F1 COARTICULATION PHENOMENA IN THE PRODUCTIONS OF GREEK SPEAKERS WITH HEARING IMPAIRMENT
- [528-530] **Charalambia Siristatidou**
DUBBING ‘HERCULES’
- [531-538] **Areti-Maria Sougari & Konstantina Iliopoulou**
INVESTIGATING LEARNERS’ ATTITUDES TOWARDS GREEK AS A SECOND LANGUAGE IN AN INTERCULTURAL SCHOOL
- [539-549] **Spyridoula Stamouli**
THE DEVELOPMENT OF NARRATIVE STRUCTURE IN GREEK L1
- [550-558] **Evangelia Thomadaki**
PARADIGM STRUCTURE, DEFECTIVENESS AND DERIVATIONAL PRODUCTIVITY
- [559-570] **Nina Topintzi & Evia Kainada**
ACRONYMS AND THE PLACEMENT OF DEFAULT STRESS IN GREEK
- [571-577] **Marina Tzakosta & Maria Hadzidaki**
WORD DERIVATION IN CHILD SPEECH: EVIDENCE FROM PRESCHOOLERS

[578-583] Marina Tzakosta & Maria Mamadaki

**COMPOUND FORMATION IN L2 LEARNING: THE CASE OF
BULGARIAN, ROMANIAN AND RUSSIAN LEARNERS OF GREEK**

[584-591] Spyridoula Varlokosta & Michaela Nerantzini

PRONOMINAL AND ANAPHORIC REFERENCE IN GREEK SPECIFIC LANGUAGE IMPAIRMENT

[592-602] Marina Vassiliou

MEASURING THE GREEK INFINITIVE THROUGH TIME

[603-611] Magdalini Vitsou

MOTHER TONGUE THEMATA: GREEK PARADIGM IN SWEDISH PRESCHOOL EDUCATION

**[612-619] Eleni Vletsi, Irene Hrisovalantou Liapi, Stavroula Stavrakaki,
Chloë Marshall & George Grouios**

ASSESSING VERBAL FLUENCY IN GREEK SIGN LANGUAGE

[623-630] Θανάσης Αγάθος, Βασιλική Γιαννακού, Βαρβάρα Δημοπούλου, Μάχη Μοντζολή, Νικόλαος Ρουμπής & Αλίκη Τσοτσορού

ΤΟ ΛΟΓΟΤΕΧΝΙΚΟ ΚΕΙΜΕΝΟ ΣΤΗΝ ΤΑΞΗ ΤΗΣ ΝΕΑΣ ΕΛΛΗΝΙΚΗΣ ΩΣ ΔΕΥΤΕΡΗΣ/ΞΕΝΗΣ ΓΛΩΣΣΑΣ: ΠΡΟΒΛΗΜΑΤΙΣΜΟΙ ΚΑΙ ΠΡΟΤΑΣΕΙΣ

[631-637] Κατερίνα Αλεξανδρή & Μαρία Καπουρκατσίδου

ΔΙΔΑΣΚΑΛΙΑ ΤΗΣ ΝΕΑΣ ΕΛΛΗΝΙΚΗΣ ΩΣ ΞΕΝΗΣ: ΑΝΑΛΥΤΙΚΟ ΠΡΟΓΡΑΜΜΑ ΓΙΑ ΤΟ ΠΡΟΧΩΡΗΜΕΝΟ ΕΠΙΠΕΔΟ ΕΛΛΗΝΟΜΑΘΕΙΑΣ (Γ1)

[638-648] Άννα Αναστασιάδη-Συμεωνίδη & Μαρία Μητσιάκη

ΠΟΣΕΣ ΨΗΦΟΙ ΣΤΟΝ ΨΗΦΟ; ΓΛΩΣΣΙΚΗ ΑΥΤΟΡΥΘΜΙΣΗ ΚΑΙ ΕΝ ΕΞΕΛΙΞΕΙ ΑΛΛΑΓΗ ΤΟΥ ΓΡΑΜΜΑΤΙΚΟΥ ΓΕΝΟΥΣ ΣΤΗ ΝΕ

[649-653] Γεωργία Ανδρέου & Μαρία Λιάκου

ΣΥΓΚΡΙΤΙΚΗ ΑΞΙΟΛΟΓΗΣΗ ΓΡΑΠΤΩΝ ΚΕΙΜΕΝΩΝ ΕΦΗΒΩΝ ΜΑΘΗΤΩΝ ΓΥΜΝΑΣΙΟΥ ΚΑΙ ΛΥΚΕΙΟΥ ΜΕ ΦΥΣΙΟΛΟΓΙΚΗ ΓΛΩΣΣΙΚΗ ΑΝΑΠΤΥΞΗ

[654-662] Μαρία Ανδριά, Imma Miralpeix & M.Luz Celaya

ΔΙΑΓΛΩΣΣΙΚΗ ΕΠΙΔΡΑΣΗ ΚΑΤΑ ΤΗΝ ΕΚΜΑΘΗΣΗ ΤΗΣ ΕΛΛΗΝΙΚΗΣ ΩΣ ΞΕΝΗΣ ΓΛΩΣΣΑΣ ΑΠΟ ΙΣΠΑΝΟΦΩΝΟΥΣ ΜΑΘΗΤΕΣ

[663-678] Σπύρος Αρμοστή, Μαριάννα Κατσογιάννου, Κυριακή Χριστοδούλου & Χαράλαμπος Θεμιστοκλέους

ΤΑΣΕΙΣ ΤΩΝ ΚΥΠΡΙΩΝ ΩΣ ΠΡΟΣ ΤΗ ΓΡΑΠΤΗ ΑΠΟΔΟΣΗ ΤΩΝ ΜΕΤΑΦΑΤΝΙΑΚΩΝ ΣΥΜΦΩΝΩΝ ΤΗΣ ΚΥΠΡΙΑΚΗΣ

[679-686] Αργύρης Αρχάκης

Η ΑΦΗΓΗΣΗ ΤΗΣ ΜΑΘΗΤΙΚΗΣ ΑΠΕΙΘΑΡΧΙΑΣ: ΑΝΑΛΥΣΗ ΣΥΝΟΜΙΛΙΑΚΩΝ ΔΕΔΟΜΕΝΩΝ

[687-695] Γεώργιος Ασπρούλης

ΚΡΙΤΗΡΙΑ ΑΞΙΟΛΟΓΗΣΗΣ ΠΛΗΡΟΦΟΡΗΤΙΚΟΤΗΤΑΣ ΜΑΘΗΤΙΚΩΝ ΚΕΙΜΕΝΩΝ

[696-707] Βασιλική Αφεντουλίδου

ΣΥΓΚΡΙΣΕΙΣ ΟΜΟΙΟΤΗΤΑΣ ΣΤΑ ΝΕΑ ΕΛΛΗΝΙΚΑ Ο ΔΕΙΚΤΗΣ ΣΑΝ

[708-716] Φρειδερίκος Βαλετόπουλος

ΠΑΡΑΤΗΡΗΣΕΙΣ ΣΤΗΝ ΕΚΜΑΘΗΣΗ ΤΗΣ ΕΛΛΗΝΙΚΗΣ ΑΠΟ ΤΟΥΣ ΓΑΛΛΟΦΩΝΟΥΣ ΔΙΔΑΣΚΟΜΕΝΟΥΣ ΤΗΝ ΕΛΛΗΝΙΚΗ ΩΣ ΞΕΝΗ ΓΛΩΣΣΑ

[717-724] Νίκος Βερβίτης, Μαρία Καπουρκατσίδου & Vojkan Stojičić

ΖΗΤΗΜΑΤΑ ΔΙΑΓΛΩΣΣΑΣ ΣΤΗΝ ΠΑΡΑΓΩΓΗ ΓΡΑΠΤΟΥ ΛΟΓΟΥ: Η ΠΕΡΙΠΤΩΣΗ ΤΩΝ ΣΕΡΒΟΦΩΝΩΝ ΦΟΙΤΗΤΩΝ ΜΕ ΓΛΩΣΣΑ ΣΤΟΧΟ ΤΗΝ ΕΛΛΗΝΙΚΗ

[725-732] Μαρία Βραχιονίδου

ΟΙ ΟΝΟΜΑΣΙΕΣ ΤΩΝ ΓΕΝΝΗΤΙΚΩΝ ΟΡΓΑΝΩΝ ΣΤΑ ΝΕΟΕΛΛΗΝΙΚΑ ΙΔΙΩΜΑΤΑ ΚΑΙ ΔΙΑΛΕΚΤΟΥΣ

[733-741] Μαριάνθη Γεωργαλίδου

ΕΡΩΤΗΣΕΙΣ ΚΑΙ ΑΠΑΝΤΗΣΕΙΣ ΣΤΟΝ ΔΗΜΟΣΙΟΓΡΑΦΙΚΟ ΚΑΙ ΔΙΚΑΝΙΚΟ ΛΟΓΟ: ΜΙΑ ΠΡΟΚΑΤΑΡΤΙΚΗ ΜΕΛΕΤΗ

[742-753] Παρασκευή Γιαννίση & Μαριάννα Κονδύλη

ΣΗΜΕΙΩΤΙΚΕΣ ΔΙΑΔΙΚΑΣΙΕΣ ΣΤΗ ΔΙΔΑΚΤΙΚΗ ΠΡΟΣΕΓΓΙΣΗ ΚΑΤΗΓΟΡΙΩΝ ΜΗ ΚΟΙΝΗΣ ΓΝΩΣΗΣ: ΟΡΙΣΜΟΙ ΚΑΙ ΤΑΞΙΝΟΜΗΣΕΙΣ ΓΕΩΜΕΤΡΙΚΩΝ ΣΧΗΜΑΤΩΝ ΑΠΟ ΠΑΙΔΙΑ ΝΗΠΙΑΓΩΓΕΙΟΥ

- [754-762] **Βούλα Γιούλη & Αγγελική Φωτοπούλου**
ΤΟ ΣΗΜΑΣΙΟΛΟΓΙΚΟ ΠΕΔΙΟ ΤΩΝ ΣΥΝΑΙΣΘΗΜΑΤΩΝ: ΤΑΞΙΝΟΜΗΣΗ ΤΩΝ ΡΗΜΑΤΩΝ
ΤΗΣ ΝΕΑΣ ΕΛΛΗΝΙΚΗΣ ΠΟΥ ΔΗΛΩΝΟΥΝ ΣΥΝΑΙΣΘΗΜΑ
- [763-772] **Διονύσης Γούτσος**
ΠΩΣ ΝΑ ΘΥΜΑΣΑΙ ΚΑΙ ΠΩΣ ΝΑ ΞΕΧΝΑΣ ΣΤΑ ΕΛΛΗΝΙΚΑ: ΔΟΜΙΚΑ ΣΧΗΜΑΤΑ ΚΑΙ ΠΡΑΞΕΙΣ
ΟΜΙΛΙΑΣ ΣΤΟ ΣΩΜΑ ΕΛΛΗΝΙΚΩΝ ΚΕΙΜΕΝΩΝ
- [773-782] **Βαρβάρα Δημοπούλου**
ΣΤΟΙΧΕΙΑ ΓΙΑ ΤΗΝ ΕΝΝΟΙΟΛΟΓΙΚΗ ΘΕΜΕΛΙΩΣΗ ΚΑΙ ΤΗ ΓΝΩΣΤΙΚΗ ΛΕΙΤΟΥΡΓΙΚΟΤΗΤΑ ΤΩΝ
ΝΕΟΕΛΛΗΝΙΚΩΝ ΙΔΙΩΜΑΤΙΚΩΝ ΕΚΦΡΑΣΕΩΝ: ΠΑΡΑΔΕΙΓΜΑΤΑ ΑΠΟ ΤΟ ΣΗΜΑΣΙΟΛΟΓΙΚΟ
ΠΕΔΙΟ ΤΗΣ ΦΥΣΕΩΣ
- [783-795] **Νίκη Ετεοκλέους, Βικτωρία Παύλου & Συμεών Τσολακίδης**
ΓΡΑΜΜΑΤΙΣΜΟΣ ΚΑΙ ΠΟΛΥΤΡΟΠΙΚΟΤΗΤΑ: ΜΕΛΕΤΗ ΠΕΡΙΠΤΩΣΗΣ ΓΙΑ ΤΗΝ ΑΞΙΟΠΟΙΗΣΗ ΤΟΥ
MULTIMEDIA BUILDER (MMB) ΑΠΟ ΜΕΛΛΟΝΤΙΚΟΥΣ ΕΚΠΑΙΔΕΥΤΙΚΟΥΣ ΣΤΗΝ ΚΥΠΡΟ
- [796-805] **Χαράλαμπος Θεμιστοκλέους**
ΤΑ ΠΥΡΗΝΙΚΑ ΤΟΝΙΚΑ ΥΨΗ ΤΗΣ ΚΥΠΡΙΑΚΗΣ ΕΛΛΗΝΙΚΗΣ
- [806-814] **Παρασκευή Θώμου**
ΣΗΜΑΣΙΟΛΟΓΙΚΗ ΑΝΑΛΥΣΗ ΠΕΡΙΠΤΩΣΕΩΝ ΜΕΤΑΦΟΡΑΣ ΧΩΡΙΣ ΚΥΡΙΟΛΕΞΙΑ ΣΕ ΧΡΗΣΗ:
ΕΠΩΜΙΖΟΜΑΙ ΤΙΣ ΕΥΘΥΝΕΣ, ΑΦΥΠΝΙΖΕΙ ΣΥΝΕΙΔΗΣΕΙΣ
- [815-826] **Έλενα Ιωαννίδου**
“ΤΙ ΕΝΝΑ ΚΑΜΟΥΜΕ Η ΤΙ ΘΑ ΚΑΝΟΥΜΕ;”
ΔΙΕΡΕΥΝΩΝΤΑΣ ΤΙΣ ΓΛΩΣΣΙΚΕΣ ΠΡΑΚΤΙΚΕΣ ΤΩΝ ΕΚΠΑΙΔΕΥΤΙΚΩΝ ΣΤΗΝ ΠΡΩΤΟΒΑΘΜΙΑ
ΚΑΙ ΔΕΥΤΕΡΟΒΑΘΜΙΑ ΔΗΜΟΣΙΑ ΕΚΠΑΙΔΕΥΣΗ ΣΤΗΝ ΚΥΠΡΟ
- [827-838] **Μαρία Καμηλάκη**
«ΚΑΙ ΟΙ ΤΟΙΧΟΙ ΕΧΟΥΝ...ΜΙΛΙΑ»: ΚΟΙΝΩΝΙΟΓΛΩΣΣΟΛΟΓΙΚΗ ΠΡΟΣΕΓΓΙΣΗ
ΤΟΥ ΧΙΟΥΜΟΡ ΣΤΟΝ ΓΡΑΠΤΟ, ΑΝΩΝΥΜΟ ΣΥΝΘΗΜΑΤΙΚΟ ΛΟΓΟ
- [839-844] **Χρυσούλα Καραντζή**
ΚΑΤΑΓΡΑΦΕΣ ΠΡΟΦΟΡΙΚΟΥ ΔΙΑΛΕΚΤΙΚΟΥ ΛΟΓΟΥ: ΠΡΟΒΛΗΜΑΤΑ ΚΑΙ ΠΡΟΚΛΗΣΕΙΣ
- [845-852] **Χρήστος Καρβούνης**
Η ΚΟΙΝΩΝΙΚΗ ΔΙΓΛΩΣΣΙΑ ΣΤΗΝ ΙΣΤΟΡΙΑ ΤΗΣ ΕΛΛΗΝΙΚΗΣ ΓΛΩΣΣΑΣ
- [853-860] **Γεωργία Κατσούδα**
Η ΕΤΥΜΟΛΟΓΗΣΗ ΣΕ ΔΙΑΛΕΚΤΙΚΑ ΓΛΩΣΣΑΡΙΑ ΚΑΙ ΛΕΞΙΚΑ:
ΠΑΡΑΔΕΙΓΜΑΤΑ ΑΠΟ ΤΟ ΚΥΘΗΡΑΪΚΟ ΙΔΙΩΜΑ
- [861-869] **Μαρία Κολιοπούλου**
ΜΕΤΑΞΥ ΣΥΝΘΕΤΩΝ ΚΑΙ ΦΡΑΣΕΩΝ
- [870-880] **Ευάγγελος Κουρδής**
ΕΝΔΟΓΛΩΣΣΙΚΗ ΜΕΤΑΦΡΑΣΗ ΚΑΤ'ΕΠΙΛΟΓΗΝ;
Η ΠΕΡΙΠΤΩΣΗ ΤΟΥ ΥΠΟΤΙΤΛΙΣΜΟΥ ΔΙΑΛΕΚΤΙΚΩΝ ΣΥΣΤΗΜΑΤΩΝ
ΤΗΣ ΕΛΛΗΝΙΚΗΣ ΓΛΩΣΣΑΣ ΣΕ ΤΗΛΕΟΠΤΙΚΑ ΔΙΑΦΗΜΙΣΤΙΚΑ ΜΗΝΥΜΑΤΑ
- [881-889] **Δημήτρης Κουτσογιάννης**
ΛΑΤΙΝΟΕΛΛΗΝΙΚΑ ΚΑΙ ΠΑΓΚΟΣΜΙΟΠΟΙΗΣΗ
- [890-898] **Δώρας Κ. Κυριαζής**
ΤΟ ΕΛΛΗΝΙΚΟ ΓΛΩΣΣΙΚΟ ΙΔΙΩΜΑ ΤΗΣ ΑΡΤΑΣ ΑΥΛΩΝΑ
- [899-904] **Irina Lobzhanidze**
ΠΕΡΙ ΠΡΟΒΛΗΜΑΤΩΝ ΤΗΣ ΚΑΤΑΡΤΙΣΗΣ ΤΟΥ ΓΕΩΡΓΙΑΝΟ-ΝΕΟΕΛΛΗΝΙΚΟΥ ΛΕΞΙΚΟΥ
ΤΩΝ ΙΔΙΩΤΙΣΜΩΝ

- [905-918] **Νικόλαος Μαθιουδάκης**
ΠΟΙΗΤΙΚΟΙ ΝΕΟΛΟΓΙΣΜΟΙ ΣΤΗΝ 'ΟΔΥΣΕΙΑ' ΤΟΥ ΝΙΚΟΥ ΚΑΖΑΝΤΖΑΚΗ: ΧΙΛΙΑΔΕΣ
ΑΘΗΣΑΥΡΙΣΤΕΣ ΛΕΞΕΙΣ ΑΝΑΖΗΤΟΥΝ ΤΗΝ ΤΑΥΤΟΤΗΤΑ ΤΟΥΣ
- [919-928] **Νικόλαος Μαθιουδάκης & Λένα Παπαδοπούλου**
ΛΕΞΙΚΟΓΡΑΦΙΚΕΣ ΕΠΙΛΟΓΕΣ ΓΙΑ ΤΗ ΣΥΓΓΡΑΦΗ ΕΝΟΣ ΠΟΙΗΜΑΤΟΣ:
ΕΝΑ ΑΔΗΜΟΣΙΕΥΤΟ ΣΗΜΕΙΩΜΑΤΑΡΙΟ ΤΟΥ ΝΙΚΟΥ ΚΑΖΑΝΤΖΑΚΗ
- [929-939] **Μαριάνθη Μακρή-Τσιλιπάκου**
Η ΑΥΤΟΔΙΟΡΘΩΣΗ/ΕΤΕΡΟΔΙΟΡΘΩΣΗ ΩΣ ΜΕΤΡΟ ΚΟΙΝΩΝΙΟΓΛΩΣΣΙΚΗΣ ΕΠΙΓΝΩΣΗΣ:
Η ΠΕΡΙΠΤΩΣΗ ΤΗΣ ΠΡΟΣΦΩΝΗΣΗΣ/ΑΝΑΦΟΡΑΣ
- [940-949] **Έλενα Μάντζαρη & Άννα Ιορδανίδου**
ΛΕΞΙΚΟΓΡΑΦΙΚΕΣ ΠΡΟΣΕΓΓΙΣΕΙΣ ΣΤΗ ΔΙΑΤΥΠΩΣΗ ΤΩΝ ΟΡΙΣΜΩΝ:
ΕΡΕΥΝΑ ΣΕ ΜΑΘΗΤΕΣ ΤΗΣ Ε΄ ΚΑΙ ΣΤ΄ ΔΗΜΟΤΙΚΟΥ
- [950-959] **Ιώ Μανωλέσσου & Χριστίνα Μπασέα-Μπεζαντάκου**
ΤΑ ΔΙΠΛΑ ΣΥΜΦΩΝΑ ΣΤΙΣ ΝΕΟΕΛΛΗΝΙΚΕΣ ΔΙΑΛΕΚΤΟΥΣ:
ΣΥΓΡΟΝΙΚΗ ΚΑΙ ΔΙΑΧΡΟΝΙΚΗ ΠΡΟΣΕΓΓΙΣΗ
- [960-964] **Ελένη Μότσιου**
ΚΑΤΗΓΟΡΙΕΣ ΠΡΑΓΜΑΤΟΛΟΓΙΚΩΝ ΦΡΑΣΕΟΛΟΓΙΣΜΩΝ
- [965-972] **Άννα Μουτή, Γεώργιος Υψηλάντης & Αντώνης Τσοπάνογλου**
ΕΞΕΤΑΖΟΝΤΑΣ ΤΗ «ΔΙΚΑΙΟΤΗΤΑ» ΣΤΑ ΤΕΣΤ ΠΟΛΛΑΠΛΗΣ ΕΠΙΛΟΓΗΣ
- [973-982] **Γεώργιος Μπατζάκας**
ΜΙΑ ΠΡΩΤΗ ΠΡΟΣΕΓΓΙΣΗ ΤΟΥ ΙΔΙΩΜΑΤΟΣ ΤΟΥ ΙΑΣΜΟΥ ΚΟΜΟΤΗΝΗΣ
- [983-989] **Θεόδωρος Μωυσιάδης**
Η ΑΟΡΙΣΤΗ ΑΝΤΩΝΥΜΙΑ *ΚΑΠΟΙΟΣ*. Ο ΣΧΗΜΑΤΙΣΜΟΣ ΚΑΙ Η ΛΕΙΤΟΥΡΓΙΑ ΤΗΣ
ΣΤΗ ΜΕΣΑΙΩΝΙΚΗ ΕΛΛΗΝΙΚΗ
- [990-999] **Θανάσης Νάκας**
ΓΙΑ ΤΟ ΝΕΟΕΛΛΗΝΙΚΟ 'ΓΕΡΟΥΝΔΙΟ' ή 'ΓΕΡΟΥΝΤΙΒΟ' ή 'ΓΕΡΟΥΝΔΙΑΚΟ'
(άλλως πως, «*far from the madding gerund*»!)
- [1000-1010] **Γεωργία Νικολάου**
ΜΟΡΦΟΛΟΓΙΚΗ ΑΝΑΛΥΣΗ ΤΩΝ ΕΠΙΘΕΤΩΝ ΤΗΣ ΝΕΑΣ ΕΛΛΗΝΙΚΗΣ
- [1011-1020] **Ελισσάβετ Νουχουτίδου**
ΡΗΜΑΤΑ ΕΞΑΡΤΗΣΗΣ ΚΑΙ ΕΠΙΛΟΓΗ ΣΥΜΠΛΗΡΩΜΑΤΙΚΟΥ ΔΕΙΚΤΗ ΣΤΟ ΜΕΣΟ
ΚΑΙ ΠΡΟΧΩΡΗΜΕΝΟ ΕΠΙΠΕΔΟ ΤΗΣ ΝΕ ΩΣ Γ2
- [1021-1029] **Νικόλαος Ντάγκας**
ΤΟ ΕΠΙΘΗΜΑ -(ι)ΛΙΚΙ ΣΤΗΝ ΚΟΙΝΗ ΝΕΟΕΛΛΗΝΙΚΗ

■ Πρόλογος |

Στον τόμο αυτό δημοσιεύονται επιλεγμένες εργασίες που παρουσιάστηκαν είτε ως αυτοτελείς ομιλίες είτε ως αναρτημένες ανακοινώσεις στο 10ο Διεθνές Συνέδριο Ελληνικής Γλωσσολογίας (ΔΣΕΓ), το οποίο πραγματοποιήθηκε στο Δημοκρίτειο Πανεπιστήμιο Θράκης κατά το διάστημα 1-4 Σεπτεμβρίου 2011 και συνδιοργανώθηκε από το Τμήμα Ελληνικής Φιλολογίας, το Τμήμα Γλώσσας, Φιλολογίας και Πολιτισμού Παρευξείνιων Χωρών και το Παιδαγωγικό Τμήμα Δημοτικής Εκπαίδευσης.

Από τις 200 εργασίες που έγιναν αρχικά δεκτές μετά από κρίση για παρουσίαση στο Συνέδριο, υποβλήθηκαν για δημοσίευση 140 περίπου και από αυτές δημοσιεύονται, έπειτα από τη διαδικασία αξιολόγησης των κειμένων, οι 119.

Προτάσσονται στον τόμο τα κείμενα των προσκεκλημένων ομιλητών με αλφαβητική σειρά. Στη συνέχεια παρατίθενται τα άρθρα στην αγγλική γλώσσα και ακολουθούν τα άρθρα στην ελληνική. Τα κείμενα παρατίθενται στον τόμο κατ' αλφαβητική σειρά, και στην περίπτωση περισσότερων του ενός συγγραφέων λαμβάνεται ως βάση το όνομα του πρώτου συγγραφέα. Ο αναγνώστης έχει τη δυνατότητα να κατεβάσει ως αρχείο pdf καθένα κείμενο ξεχωριστά, αλλά και ολόκληρο τον τόμο.

Ως οργανωτική επιτροπή και επιτροπή έκδοσης των πρακτικών του 10ου ΔΣΕΓ θα θέλαμε να ευχαριστήσουμε θερμά όλους όσους συμμετείχαν στο συνέδριο, είτε υπέβαλαν τις εργασίες τους για δημοσίευση στον τόμο αυτόν είτε όχι.

Θα θέλαμε ακόμη να ευχαριστήσουμε ιδιαίτερα τους προσκεκλημένους ομιλητές μας κκ. Jean-Claude Anscombre, Ομότιμο Διευθυντή Έρευνας στο Εθνικό Κέντρο Επιστημονικών Ερευνών (CNRS), Άννα Αναστασιάδη Συμεωνίδη, Καθηγήτρια του Αριστοτελείου Πανεπιστημίου Θεσσαλονίκης, Αναστασία Γιαννακίδου, Καθηγήτρια του Πανεπιστημίου του Σικάγου, Ursula Stephany, Καθηγήτρια του Πανεπιστημίου της Κολωνίας, Igor Mel'cuk, Καθηγητή του Πανεπιστημίου του Μόντρεαλ, Pius Ten Hacken, Καθηγητή του Πανεπιστημίου Swansea, Χριστόφορο Χαραλαμπίκη, Καθηγητή του Εθνικού και Καποδιστριακού Πανεπιστημίου Αθηνών, οι οποίοι με το κύρος και την επιστημονικότητά τους συνεισέφεραν τα μέγιστα στην επιτυχία του συνεδρίου.

Είμαστε, επίσης, ιδιαίτερα ευγνώμονες στους κριτές –εσωτερικούς και εξωτερικούς– που διέθεσαν μέρος του πολύτιμου χρόνου τους για την αξιολόγηση τόσο των περιλήψεων, όσο και των κειμένων που κατατέθηκαν προς δημοσίευση. Η βοήθειά τους ήταν καθοριστική όχι μόνο για την επιλογή των ανακοινώσεων που παρουσιάστηκαν στο συνέδριο, αλλά και για τη διασφάλιση της επιστημονικότητας και της ποιότητας του παρόντος τόμου. Ωστόσο, θα θέλαμε να υπογραμμίσουμε ότι την ευθύνη για την τελική μορφή των άρθρων που περιέχει ο τόμος αυτός φέρουν αποκλειστικά οι συγγραφείς, οι οποίοι είχαν την ευκαιρία να επανεξετάσουν τις υπό έκδοση εργασίες τους μετά τη διαδικασία της αξιολόγησης.

Θα θέλαμε να ευχαριστήσουμε επίσης όλους τους συναδέλφους, εθελοντές φοιτητές

και τα μέλη του διοικητικού προσωπικού του Δημοκρίτειου Πανεπιστημίου Θράκης, που βοήθησαν στη διοργάνωση του συνεδρίου, στην επιτυχή διεξαγωγή του και στην έκδοση των Πρακτικών. Ιδιαίτερως ευχαριστούμε τη διδάσκουσα με σύμβαση του Π.Δ 407 στο Παιδαγωγικό Τμήμα Δημοτικής Εκπαίδευσης-ΔΠΘ κ. Παπαδοπούλου Ελένη, τον διδάκτορα του Τμήματος Ελληνικής Φιλολογίας, κ. Νικόλαο Μαθιουδάκη, καθώς και την υποψήφια διδάκτορα του Τμήματος Ελληνικής Φιλολογίας κ. Ελίνα Χατζηπαπά για την ουσιαστική συμβολή τους στη διαδικασία αξιολόγησης (εκπόνηση καταλόγων με τις υπό κρίση εργασίες, διεκπεραίωση ηλεκτρονικής αλληλογραφίας με συγγραφείς και αξιολογητές), επιμέλειας και μορφοποίησης των πρακτικών.

Τέλος, το 10ο ΔΣΕΓ δεν θα μπορούσε να πραγματοποιηθεί χωρίς την οικονομική ενίσχυση του Δημοκρίτειου Πανεπιστημίου Θράκης, στο οποίο είμαστε ευγνώμονες για την οικονομική του συνεισφορά.

■ Introduction |

This volume contains selected papers from the 10th International Conference of Greek Linguistics (ICGL), held at Democritus University of Thrace, Komotini - Greece, (1st – 4th September 2011). The conference was co-organized by the Department of Greek, the Department of Language, Literature and Culture of Black Sea Countries and the Department of Primary Education.

Out of the 200 abstracts approved after the initial reviewing and presented at the Conference (posters included), approximately 140 were submitted and 119 were finally accepted for publication after a peer reviewing process. As Editors of the present volume, we would like to express our warmest thanks to all contributors, whether they submitted a paper for publication in this volume or not.

The volume is organized as follows: The first section contains the contributions of the invited speakers followed by the papers in English and finally by the papers in Greek, all set out in alphabetical order (in case of multiple authors, the name of the first author is taken into account). Readers can download not only single papers but also the entire volume in pdf format.

Special thanks are due to our invited speakers who were kind enough to travel to Komotini and deliver their keynote speeches in various fields of Linguistics, thereby contributing substantially to the success of the conference: Professor Jean-Claude Anscombre, Honorary Research Director at the National Center of Scientific Research (CNRS), Professor Anna Anastasiades-Symeonides, Aristotle University of Thessaloniki, Professor Anastasia Giannakidou, University of Chicago, Professor Ursula Stephany, University of Cologne, Professor Igor Mel'cuk, University of Montreal, Professor Pius Ten Hacken, University of Wales and Professor Christoforos Charalambakis, National University of Athens.

We are also deeply indebted to our reviewers –both internal and external– for devoting much of their precious time to reviewing the abstracts and papers. Their contribution was invaluable not only in the selection of the abstracts but also as a means of safeguarding the scientific quality of the present volume. Nevertheless, it should be pointed out that the responsibility for the final form of each paper lies ultimately with the author(s), as they had the chance to approve their texts after the process of peer reviewing.

We would like to thank all colleagues, volunteer students and administrative staff of Democritus University who contributed in various ways to the success of the conference and the publication of the proceedings. Special mention must be made for Dr. Eleni Papadopoulou, Adjunct Lecturer at the Department of Primary Education, Dr. Nikolaos Mathioudakis (Department of Greek) and Ms. Elina Chadjipapa, PhD student, (Department of Greek) for their assistance in the procedure of evaluation (listing the papers to be reviewed, handling the electronic

correspondence with authors and reviewers) as well as in improving the final layout of the proceedings.

The Conference received financial support from the Democritus University of Thrace, which is hereby gratefully acknowledged.

ABSTRACT

The aim of this paper is to propose a new morphological classification of the Modern Greek nouns that leads to a deeper understanding of the language system. Our description is based on the theory of Paradigm Function Morphology (Stump 2001), which is an inferential-realizational theory of inflection, and the theoretical model advanced by Bonami & Boyé (2003, 2004, 2006, 2009, 2011). We begin by presenting the existing classifications of Greek nouns and we move on to our own proposal which includes six inflectional classes, and its predictions.

Keywords: paradigm function morphology, thematic space, prototypical inflectional system, disponibility of inflectional classes, vocative, [+/-learned], stem recognisability, economy

1. Εισαγωγή

Πολλοί ερευνητές έχουν ασχοληθεί τόσο από συγχρονική όσο και από διαχρονική σκοπιά με το ζήτημα της περιγραφής και ερμηνείας του συστήματος κλίσης των ουσιαστικών της Νέας Ελληνικής (NE) χρησιμοποιώντας ένα θεωρητικό πλαίσιο είτε με ρητό τρόπο π.χ. Μαλικούτη (1970), Ralli/Ράλλη (1994, 1998, 1999, 2000, 2001, 2002, 2003) είτε –το συνηθέστερο– με άρρητο.

Στην ανακοίνωση αυτή, με βάση το θεωρητικό πλαίσιο της Μορφολογίας των Παραδειγματικών Συναρτήσεων (Stump 2001) όπως συμπληρώθηκε από τους Olivier Bonami και Gilles Boyé (2003, 2004, 2006, 2009, 2011), θα επιχειρήσουμε αφενός μια περιγραφή του νεοελληνικού κλιτικού συστήματος των ουσιαστικών και αφετέρου μια ερμηνεία συναφών φαινομένων που αναδεικνύουν τις τάσεις του συστήματος. Για το σκοπό αυτό εξετάσαμε πάνω από 80 000 ουσιαστικά, που είναι λημματογραφημένα στο *Αντίστροφο λεξικό της νέας ελληνικής* (Αναστασιάδη-Συμεωνίδη 2002). Έτσι, σύμφωνα με την ερμηνεία αυτή, το σύστημα μας αποκαλύπτεται σε όλη του την απλότητα παρά τη φαινομενική περιπλοκότητά του, και η περιγραφή επιτυγχάνεται με έναν τρόπο ιδιαίτερα οικονομικό: 6 τάξεις αρκούν για να περιγράψουν το σύνολο των κλιτών ουσιαστικών της NE.

Ο συσχετισμός κλιτικής τάξης και συχνότητας τύπου, ο συσχετισμός θέματος και φαινομένων κλίσης/παράγωγής καθώς και η έννοια του θεματικού κλιτικού χώρου για κάθε θέμα ενός ουσιαστικού επιτρέπουν όχι μόνο την περιγραφή με ανάγλυφο τρόπο του νεοελληνικού συστήματος, αλλά και ποικίλες προβλέψεις όπως το είδος των θεμάτων ενός ουσιαστικού και κατ' επέκταση της κλιτικής τάξης του.

Η εργασία αυτή αποτελείται από 3 μέρη:

- 1) Βιβλιογραφική ανασκόπηση σε Γραμματικές και μονογραφίες του κλιτικού συστήματος του ουσιαστικού
- 2) Παρουσίαση της πρότασής μας
- 3) Συμπεράσματα για το πρωτοτυπικό κλιτικό σύστημα της NE και εφαρμογές.

¹ Ευχαριστώ θερμά τον κ. Olivier Bonami, καθ. στο Παν/μιο Paris IV, που με περισσή ανιδιοτέλεια ανέλαβε να επιμορφώσει μικρή ομάδα ελλήνων γλωσσολόγων στο θεωρητικό πλαίσιο που έχει επιλεγεί στην εργασία αυτή, την κ. Δήμητρα Αλεξανδρίδου, υποψ. διδάκτορα, που προχώρησε με γνώση και υπομονή στον έλεγχο της πρότασης αυτής εφαρμόζοντάς την στο πλήθος των ουσιαστικών της NE καθώς και τη συνάδελφο Ανθή Ρεβυθιάδου για την προσεκτική ανάγνωση του κειμένου.

2. Βιβλιογραφική ανασκόπηση

Θα επιχειρήσουμε με συνοπτικό τρόπο να φωτίσουμε τις αρχές που υιοθετήθηκαν από τα σύγχρονα κείμενα κατά την ταξινόμηση των ουσιαστικών σε κλιτικές τάξεις.² Η κλιτική τάξη (KT) είναι ο μορφολογικός δείκτης της ομάδας των τύπων που περιλαμβάνονται στο κλιτικό παράδειγμα μιας λέξης, παρέχει ταξινόμηση στα ουσιαστικά και μετέχει στο σχηματισμό λέξεων για να εξασφαλίσει το σωστό συνδυασμό θεμάτων και επιθημάτων (Ράλλη 2003: 64, 66).

2.1 Μανόλης Τριανταφυλλίδης (1941)

Η κατηγοριοποίησή του στηρίζεται στις 3 τιμές του γένους: η α' κλίση περιλαμβάνει τα αρσενικά, η β' τα θηλυκά και η γ' τα ουδέτερα. Κάθε κλίση περιλαμβάνει πολλές KT. Ωστόσο δεν υπάρχει πλήρης αντιστοίχιση γένους και KT ούτε προβλεπτότητα. Η κατηγοριοποίηση αυτή εξυπηρετεί μάλλον πρακτικούς λόγους.³

2.2 Mirambel (1959)

Ο Mirambel θεωρεί ότι κάθε κλιτή λέξη αποτελείται από το θέμα (το αμετάβλητο στοιχείο) και την κατάληξη (το μεταβλητό στοιχείο), και ενδεχομένως από ένα επίθημα,⁴ που παρεμβάλλεται ανάμεσα στο θέμα και στην κατάληξη, όπως το -τ- στα ουδέτερα περιττοσύλλαβα π.χ. *μάλαμα/μαλάμα-τ-ος* ή το -δ- στα αρσενικά και θηλυκά περιττοσύλλαβα π.χ. *καβγάς/καγβά-δ-ες*, *κυρά/κυρά-δ-ες*.

Το θέμα διατηρεί σταθερά τη μορφή και το σημασιολογικό του περιεχόμενο. Επισημαίνει ότι ο τόνος (1959: 66) δεν είναι το στοιχείο που προσδιορίζει την KT. Το ονοματικό σύστημα παρουσιάζει την τάση να σταθεροποιήσει τον τόνο σε μια θέση σε όλους τους τύπους του. Ο αρχικός τόνος, αν μετατεθεί, θα μετατεθεί προς τα δεξιά. Η μετακίνηση του τόνου είναι ένα από τα χαρακτηριστικά που διαφοροποιεί την κλίση του ουσιαστικού από του επιθέτου, πβ. *πόλεμος/πολέμου* – *όμορφος/όμορφου*, *γυναίκα/γυναίκων* – *τίμια/τίμιων*. Δηλ. τα ουσιαστικά ξεχωρίζουν από τα άλλα ονοματικά στοιχεία (επίθετα, αριθμητικά) ως προς το ότι κατά την κλίση τους έχουν τόνο άλλοτε σταθερό άλλοτε κινητό. Κατά τον Mirambel (1959: 67) το ονοματικό σύστημα χαρακτηρίζεται από α) την ενότητα του θέματος στο εσωτερικό της λέξης, β) την ενδεχόμενη παρέμβαση επιθημάτων, γ) τη συστηματική μεταβολή των καταλήξεων. Η λόγια κλίση αγνοεί το -δ-, ο τόνος είναι κινητός και οι KT ποικίλλουν κατά τη φύση του θέματος, αν δηλ. είναι φωνηεντικό ή συμφωνικό. Η δημοτική, ενοποιώντας τα θέματά της, ενοποιεί και τις KT της και παρουσιάζει μεγαλύτερη ομοιογένεια στο κλιτικό της σύστημα. Η διάκριση των γενών είναι η γενική αρχή που διέπει την κλίση των ονομάτων στη ΝΕ.

Διακρίνει (1959: 89) την κλίση με 4 όρους, λ.χ. *αδερφός-ού-ό-έ*, την κλίση με 3 όρους, λ.χ. *αδερφοί-ών-ούς*, την κλίση με 2 όρους όπου εμπίπτουν τα περισσότερα ουσιαστικά, λ.χ. *μυαλό-ού*, *πουλί-ού*, *περιστάσεις-σεων*, *λάθος-ους*, *χειμώνες-ων*, *γάλα-τος*, *γάλατα-ων*, *τέρας-τέρατος*, *φαγάδες-ων*. Η ταξινόμησή του στηρίζεται καταρχήν στον αριθμό των διαφορετικών πτώσεων (δίπτωτα/τρίπτωτα/τετράπτωτα), στη συνέχεια στο γένος, στη μεταβολή ή μη του θεματικού φωνήεντος και τέλος στην προσθήκη ή μη επενθετικού συμφώνου. Τέλος, είναι φανερό ότι ο Mirambel

² Δε θα ασχοληθώ με παλαιότερες Γραμματικές όπως ήταν η αρχική μου σκέψη, γιατί περιγράφουν παλαιότερες φάσεις της ελληνικής, π.χ. ο Simon Portius στη Γραμματική του (1638: 15): *ο κλέφτης/του κλέφτου*. Επίσης ο Νικόλαος Σοφιανός (1874) π.χ. διακρίνει 7 KT: στην α' εντάσσονται τα αρσενικά σε -ας, -ης, -ις, -υς λ.χ. *προφήτης*, στη β' εντάσσονται τα θηλυκά σε -α και -η λ.χ. *ημέρα*, στην γ' εντάσσονται αρσενικά και θηλυκά σε -ος π.χ. *λόγος* και ουδέτερα σε -ον, -ί, -ι, π.χ. *ξύλον*, *ψωμί*. Στην δ' εντάσσονται αρσενικά σε -ας (γεν. -ος) π.χ. *άνδρας/ανδρός*, θηλυκά και ουδέτερα σε -α/-ος π.χ. *γυναίκα/γυναίκος*, *ένα/ένος*, στην ε' τάξη εντάσσονται αρσενικά επίθετα σε -ούς π.χ. *απλούς* και θηλυκά σε -ού π.χ. *αλεπού*, στην στ' εντάσσονται αρσενικά σε -ης/-ους π.χ. *Δημοσθένης* και ουδέτερα σε -ος/-ους π.χ. *γένος*. Τέλος στην ζ' εντάσσονται τα ανισοσύλλαβα αρσενικά, θηλυκά και ουδέτερα με γενική σε -ος/-ως π.χ. *Αίας/Αιάτος*, *κακότης/κακότητος*, *φύσις/φύσεως*, *στρώμα/στρώματος*. Σε νεότερες Γραμματικές καταγράφεται η γλωσσική αλλαγή συγκριτικά με την ΑΕ. Το ίδιο και ο Jannaris (1897) και ο Δυοβουνιώτης στη Γραμματική του Μητροφάνους Κριτοπούλου, π.χ. (1924: 108) «Των ονομάτων της πρώτης κλίσεως τα μεν εις ας περατούνται τα δε εις ης οίον ο Αινείας, ο Χρύσης. Τούτων η γενική λήγει εις α ή εις η οίον του Αινεία, του Χρύση, αντί του Αινείου, του Χρύσου». Ευχαριστώ την Ιώ Μανωλέσσου για τη σχετική βιβλιογραφία έντυπη και ηλεκτρονική.

³ Βλ. και Aronoff 1994 και Ράλλη/Ralli 1994, 1998, 1999, 2000, 2003: 64.

⁴ Δεν πρόκειται για επίθημα σύμφωνα με τον αποδεκτό σήμερα ορισμό του επιθήματος, αλλά για ένα στοιχείο χωρίς σημασιολογικό περιεχόμενο. Άλλωστε ο ίδιος το -δ- το ονομάζει αλλού (1959: 67) σχηματιστικό επίθημα.

έχει επηρεαστεί από το δομισμό, πράγμα που έχει ως αποτέλεσμα μια πολύ προσεγμένη περιγραφή του ΝΕ κλιτικού συστήματος, που συνοδεύεται από πάμπολλες εύστοχες παρατηρήσεις.

2.3 Μαλικούτη (1970)

Η Μαλικούτη περιγράφει ενδελεχώς υπό το πρίσμα της μετασχηματιστικής θεωρίας το κλιτικό σύστημα της ΝΕ και επικεντρώνεται στο να παραχθούν με συστηματικότητα συνδυαστικά τόσο στη δημοτική όσο και στην καθαρεύουσα οι διάφοροι κλιτικοί τύποι ενός ουσιαστικού με αναγωγή σε ενιαίο υποκείμενο σύστημα και με τη βοήθεια 21 φωνολογικών κανόνων, 4 κανόνων επανασχηματισμού βάσης και 7 κανόνων επανασχηματισμού καταλήξεων. Αναγνωρίζει 17 σχήματα ονομαστικών βάσεων και παρουσιάζει κατανομή των σχημάτων των καταλήξεων (1970: 89).

Ωστόσο πρόκειται για περιγραφή που ως προς τις επιστημονικές αρχές στηρίζεται σε προηγούμενο μοντέλο του Chomsky και ως προς τη γλώσσα αντικείμενο περιγραφής σε παρωχημένη μορφή της ΝΕ.

2.4 Sotiropoulos (1972)

Ο Sotiropoulos ως προς τη μεθοδολογία της μορφολογικής ανάλυσης ακολουθεί το μοντέλο στοιχείο και διάταξη (1972: 19), δηλ. στηρίζεται στα στοιχεία, τα τεμάχιά τους και την κατανομή τους. Τα ουσιαστικά αποτελούνται από θέματα (stems) και κλιτικά επιθήματα και εξετάζονται οι συνθήκες εμφάνισής τους. Το θέμα αποτελείται από τη βάση ή (στην πιο σύνθετη μορφή) από πρόθημα, βάση και (παραγωγικό) επίθημα (1972: 34), ενώ το κλιτικό επίθημα είτε ακολουθεί τη βάση είτε το (παραγωγικό) επίθημα (1972: 36). Τα ουσιαστικά διαιρούνται σε 3 ΚΤ και σε 8 υποκατηγορίες με βάση τα κλιτικά επιθήματα (1972: 36). Η α' ΚΤ περιλαμβάνει τα αρσενικά, η β' ΚΤ τα θηλυκά και η γ' τα ουδέτερα. Π.χ. η α' ΚΤ στον ενικό διαφοροποιείται από τη β' ΚΤ με βάση τα αλλόμορφα -ς και Ø στην ονομαστική (1972: 37). Στον πληθυντικό τα αλλόμορφα -η και -α της γ' ΚΤ διαφοροποιούνται από το αλλόμορφο -ες των ΚΤ α' και β' (1972: 38).

2.5 Joseph & Philippaki-Warbuton (1987: 122, 152)

Για τους Joseph & Philippaki-Warbuton οι κλιτικές τάξεις καθορίζονται ενμέρει από το ληκτικό στοιχείο του θέματος και ενμέρει από το γένος.

Παρατηρήσεις

Στις σ. 154-155 δίνονται τα κλιτικά παραδείγματα των κυριότερων ομαλών αλλά και ανώμαλων τάξεων. Ωστόσο στα ομαλά κατατάσσεται το *άνθρωπος* και στα ανώμαλα το *γιαγιά*. Για μας ισχύει το ακριβώς αντίθετο.

2.6 Mackridge (1990: 214-220)

Ο Mackridge προτείνει τριμερή διάκριση με βάση τις καταλήξεις.

1. Στην κατηγορία 1 εντάσσει τα ουσιαστικά που έχουν κοινές καταλήξεις στον πληθυντικό, αλλά διαφορετικές στον ενικό ανάλογα με το γένος, αρσενικό ή θηλυκό, π.χ. *φύλακας, κλέφτης – θάλασσα, τέχνη*. Ωστόσο εδώ εντάσσονται και τα ανισοσύλλαβα, π.χ. *παπάς, καφές, καφετζής, παππούς – γιαγιά, αλεπού*, αλλά και τα αρσενικά ή θηλυκά ουσ. με πληθ. σε -είς [-is], π.χ. *συγγραφέας, συγγενής – κυβέρνηση*.
2. Στην κατηγορία 2 εντάσσονται τα ουσιαστικά που σχηματίζουν τη γενική ενικού σε -ου, αρσενικά και ουδέτερα και ορισμένα θηλυκά, π.χ. *άνθρωπος, αγόρι – δωμάτιο*.
3. Στην κατηγορία 3 όλα τα υπόλοιπα, ισοσύλλαβα και ανισοσύλλαβα, π.χ. *έδαφος – όνομα, πλύσιμο, κρέας, φως, παρόν*.

Η ταξινόμηση αυτή, όπου καταβάλλεται προσπάθεια για πληρότητα αλλά και για ταυτόχρονη μείωση των ΚΤ, πέρα από τον υπολειμματικό χαρακτήρα της κατηγορίας 3, δεν έχει προβλεπτικό χαρακτήρα, δηλ. δεν μπορεί να προβλεφθεί ότι ο πληθ. του *τσομπάνης* είναι *τσομπάνηδες* και όχι **τσομπάνες* κατά το *κλέφτες*, αφού και τα δύο εντάσσονται στην κατηγορία 1.

2.7 Θωμαδάκη (1994)

Η θεωρία της Λεξικής Μορφολογίας (ισχυρή εκδοχή της Λεξικιστικής Υπόθεσης) αποτελεί το βασικό θεωρητικό πλαίσιο, το οποίο συμπληρώνεται από προτάσεις του Wurzel στο πλαίσιο του μοντέλου της Φυσικής Μορφολογίας κυρίως όσον αφορά την υπόθεση περί Δομικών Συνθηκών Παραδείγματος (1994: 68). Οι κανόνες κλίσης, παραγωγής και σύνθεσης ανήκουν στον Τομέα Λεξικής Δομής και ακολουθείται η θεωρία των λεξικών επιπέδων στα οποία διαμοιράζονται τα προσφύματα μιας γλώσσας. Ωστόσο η μορφοματική σύλληψη της μορφολογίας (1994: 50), η υιοθέτηση της παρωχημένης θεωρίας των λεξικών επιπέδων, καθώς και το ότι δε λαμβάνονται υπόψη η έννοια του θεματικού χώρου,⁵ ο αριθμός των μελών των ΚΤ, η συχνότητα, η διαθεσιμότητα των ΚΤ, η διάκριση σε κεντρικές/πρωτοτυπικές ΚΤ και μη συνιστούν βασικές επιλογές που διαφοροποιούν ριζικά την πρότασή μας. Ως συνέπεια της περιγραφής αυτής τα ουσιαστικά σε -ος όπως *δρόμος* παρουσιάζονται να αποτελούν αντιπροσωπευτικές περιπτώσεις του ΝΕ κλιτικού συστήματος (1994: 100, 141), ενώ για μας πρόκειται για μη διαθέσιμη ΚΤ.

2.8 Κλαίρης & Μπαμπινιώτης (1996, 2005: 18-22)

Οι Κλαίρης & Μπαμπινιώτης λαμβάνουν ως βασικό κριτήριο το αν το ουσιαστικό είναι δικατάληκτο ή τρικατάληκτο,⁶ στη συνέχεια εξετάζεται το ζήτημα της ισοσυλλαβίας/ανισοσυλλαβίας⁷ και ως τρίτο κριτήριο λαμβάνεται το γένος.

ΟΝΟΜΑΤΑ							
Δικατάληκτα						Τρικατάληκτα	
ισοσύλλαβα			ανισοσύλλαβα			ισοσύλλαβα	
αρσ. <i>ταμίας</i>	θηλ. <i>βρύση</i>	ουδ. <i>ποσό</i>	αρσ. <i>παππούς</i>	θηλ. <i>μαμά</i>	ουδ. <i>σώμα</i>	αρσ. <i>φίλος</i>	θηλ. <i>είσοδος</i>

Παρατηρήσεις

Η ταξινόμηση αυτή πρωτοτυπεί ως προς τα κριτήρια που λαμβάνει υπόψη καθώς και ως προς την ιεράρχησή τους και καταλήγει σε μια συνεπή περιγραφή. Ωστόσο και πάλι χάνεται το ανάγλυφο του συστήματος.

Το μεγαλύτερο πρόβλημα της ταξινόμησης αυτής είναι ότι ουσιαστικά με τα ίδια κλιτικά μορφήματα εντάσσονται σε διαφορετικές τάξεις και ουσιαστικά με διαφορετικά κλιτικά μορφήματα εντάσσονται στην ίδια τάξη, π.χ. το κλιτικό της γενικής -ου βρίσκεται τόσο στα ισοσύλλαβα δικατάληκτα (*ποσό*) όσο και στα τρικατάληκτα (*φίλος*) ή ακόμη τα *ταμίας*, *βρύση* και *ποσό* έχουν διαφορετικά κλιτικά μορφήματα στη γενική ενικού. (Βλ. και Tonnet 2006: 70.)

Στην κατηγορία *ταμίας* εντάσσονται και ουσ. όπως *αποστολέας/αποστολείς*, το οποίο παρουσιάζει μία συλλαβή λιγότερη στον πληθυντικό αριθμό και με βάση τον ορισμό της ανισοσυλλαβίας θα έπρεπε να ενταχθεί στα ανισοσύλλαβα, έστω και αν η επιπλέον συλλαβή εμφανίζεται στον ενικό.

Η κατηγορία τρικατάληκτα περιλαμβάνει τα αρσενικά και θηλυκά ουσιαστικά σε -ος χωρίς να γίνει αναφορά στο ανάγλυφο, ότι δηλ. τα θηλυκά έχουν περιορισμένη συχνότητα τύπου.

2.9 Ράλλη (2003)

Η Ράλλη σε πολλά άρθρα της ασχολείται με το κλιτικό σύστημα της ΝΕ. Ειδικότερα για την κλίση του ουσιαστικού (1994, 2000, 2003: 71 κεξ.) προτείνει 8 ΚΤ:

ΚΤ1 αρσενικά, θηλυκά π.χ. *άνθρωπος*, *ψήφος*

⁵ Η προτεινόμενη θεματική αλλομορφία αφενός έχει περιορισμένη εμβέλεια, γιατί αφορά μόνο ορισμένες κατηγορίες ουσιαστικών, λ.χ. τα ανισοσύλλαβα αρσενικά και θηλυκά ουσιαστικά (1994: 174, 152, 197, 209) και αφετέρου οδηγεί σε διπλή λημματογράφηση στο Σταθερό Λεξικό στην περίπτωση προαιρετικότητας (1994: 183).

⁶ Υιοθετείται η πρόταση του Κουρμούλη (1964).

⁷ Ισοσύλλαβα είναι τα ουσιαστικά των οποίων όλοι οι τύποι εμφανίζουν ίσο αριθμό συλλαβών. Ανισοσύλλαβα είναι τα ουσιαστικά των οποίων ορισμένοι τύποι εμφανίζουν μία συλλαβή παραπάνω (2005: 18).

KT2 αρσενικά π.χ. *μαθητής, φύλακας, κεφτές, παππούς*
 KT3 θηλυκά π.χ. *τύχη, χαρά, αλεπού*
 KT4 θηλυκά π.χ. *πόλη*
 KT5 ουδέτερα π.χ. *βιβλίο*
 KT6 ουδέτερα π.χ. *παιδί*
 KT7 ουδέτερα π.χ. *κράτος*
 KT8 ουδέτερα π.χ. *χώμα*

Ωστόσο ο μεγάλος αριθμός αλλομορφικών κανόνων (κυρίως σε θέματα) που προϋποτίθεται, π.χ. *αγορα-* vs. *αγορ-* vs. *αγορο-* καθώς και το ότι δε λαμβάνεται υπόψη ο αριθμός των μελών των ΚΤ δεν αφήνουν πολλά περιθώρια για προβλέψεις. Επίσης η ΚΤ1 (2003: 75) χαρακτηρίζεται ως η πιο κοινή, ενώ για μας δεν είναι πλέον διαθέσιμη.

2.10 Holton & Mackridge & Φιλιππάκη-Warburton (2004/2007: 42-66)

Οι συγγραφείς υιοθετούν την τριμερή κατηγοριοποίηση κατά γένος και δευτερευόντως στο εσωτερικό κάθε κατηγορίας λαμβάνεται υπόψη η κατάληξη της ονομαστικής ενικού. Έτσι διακρίνονται 8 κατηγορίες αρσενικών, 8 θηλυκών και 6 ουδέτερων (2007: 43).

Η ταξινόμηση αυτή, όπου καταβάλλεται προσπάθεια για πληρότητα αλλά και για ταυτόχρονη μείωση των ΚΤ, αντιμετωπίζει ισοπεδωτικά το συχνό και το μη συχνό, το διαθέσιμο και το μη διαθέσιμο πια, π.χ. τα ουσιαστικά σε *-ος* μπορεί να είναι αρσενικά, θηλυκά ή ουδέτερα (2007: 42), ενώ πρόκειται για κατηγορία μη διαθέσιμη της οποίας τα μέλη διαφέρουν ως προς τη συχνότητα τύπου, αφού τα θηλυκά και τα ουδέτερα έχουν ιδιαίτερα χαμηλή συχνότητα τύπου σε αντίθεση με τα αρσενικά.

2.11 Tonnet (2006: 70-87)

Ο Tonnet προτείνει για τρεις λόγους ένα σύστημα τεσσάρων κλιτικών τάξεων που αναπαράγει ενμέρει τις δομές του ΑΕ κλιτικού συστήματος. Το σύστημα αυτό (2006: 70-71) 1) αναδεικνύει τη συνέχεια της ελληνικής, 2) επιτρέπει την απρόσκοπτη ενσωμάτωση των στοιχείων που η δημοτική δανείστηκε από την καθαρεύουσα, και ιδίως 3) ομαδοποιεί στην ίδια κλιτική τάξη τα ουσιαστικά που έχουν εν μέρει ή ενόλω τα ίδια κλιτικά μορφήματα. Στην α' τάξη ανήκουν τα αρσενικά και θηλυκά ουσιαστικά που σχηματίζουν την ονομαστική/αιτιατική πληθυντικού με το κλιτικό *-ες/-δες*. Στη β' τάξη ανήκουν όσα σχηματίζουν τη γενική ενικού με το κλιτικό *-ου*, π.χ. *φίλος, Τήνος, παιδί, δημαρχείο*. Τα περισσότερα είναι αρσενικά, λίγα και [+λόγια] είναι θηλυκά⁸ και πολλά ουδέτερα. Στην γ' τάξη ανήκουν τα ουδέτερα ουσιαστικά σε *-μα* και σε *-ος* που σχηματίζουν τη γενική ενικού με το κλιτικό *-ος* ή *-ους*, π.χ. *μάθημα, έδαφος*. Τέλος στην δ' τάξη ανήκουν όσα στην ονομαστική/αιτιατική πληθυντικού έχουν το κλιτικό *-εις*. Πρόκειται για μικτή τάξη όπου τα ουσιαστικά στον ενικό κλίνονται όπως τα ουσιαστικά της α' τάξης και στον πληθυντικό όπως τα ουσιαστικά της ΑΕ γ' τάξης, π.χ. *συγγραφέας, κατάσταση, πόλη*.

Θετικό στοιχείο της ταξινόμησης αυτής είναι το ότι γίνεται μνεία της συχνότητας τύπου, λ.χ. ότι η α' τάξη, που περιλαμβάνει τα πρωτόκλιτα και ενμέρει τα τριτόκλιτα της ΑΕ, έχει τα περισσότερα μέλη.

2.12 Kyriacopoulou & Martineau & Yannacopoulou (2006)

Οι συγγραφείς διακρίνουν 887 ΚΤ. Περιγράφονται με πληρότητα και λεπτολογία 64 951 ουσιαστικά.⁹ Ο τόνος υπολογίζεται με ένα σύστημα κανόνων με βάση την τονισμένη συλλαβή στο λημματικό τύπο. Στη φάση που βρίσκεται τώρα το Ηλεκτρονικό Λεξικό των μονολεκτικών ουσιαστικών (Delas) της ΝΕ, που σχεδιάστηκε και αναπτύσσεται από τη μονάδα αυτόματης επεξεργασίας φυσικών γλωσσών (<http://linginfo.frl.auth.gr>) του Εργαστηρίου Μετάφρασης και Επεξεργασίας του Λόγου ΑΠΘ, περιλαμβάνει 64 951 λημματικούς τύπους, που αντιστοιχούν σε 268 645 κλιτούς τύπους. Κάθε λημματικός τύπος συνοδεύεται από έναν κλιτικό κωδικό αριθμό, που αποτελείται από ένα τμήμα

⁸ Για το λόγο αυτό τα θηλυκά εγκαταλείπουν την τάξη αυτή και εντάσσονται στην α' τάξη, όπου αποκτούν [-λόγια] μορφή, λ.χ. *η Τήνος* → *η Τήνο/της Τήνος*.

⁹ Σήμερα αυτό το ηλεκτρονικό λεξικό αυτόματης κλίσης μονολεκτικών ουσιαστικών περιλαμβάνει 181736 ουσιαστικά κοινά και κύρια (ανθρωπωνύμια και τοπωνύμια).

αλφαβητικό (με γράμματα) που προσδιορίζουν τη γραμματική κατηγορία (το μέρος του λόγου), και ένα τμήμα αριθμητικό που αναφέρεται σε έναν κλιτικό πίνακα με τη μορφή καταλόγου κλιτικών διανυσμάτων.

Ωστόσο δεν υπάρχει δυνατότητα προβλεπτότητας ούτε λαμβάνονται υπόψη αριθμητικά δεδομένα για τη διάκριση ανάμεσα σε πρωτοτυπικές ΚΤ και μη.

2.13 Χατζησαββίδης (2009 : 149-173)

Ο Χατζησαββίδης διακρίνει 3 ΚΤ και πολλές υποκατηγορίες με βάση το γένος, την ισοσυλλαβία και τέλος τα ανώμαλα ουσιαστικά. Έτσι η α΄ ΚΤ περιλαμβάνει τα αρσενικά, η β΄ τα θηλυκά και η γ΄ τα ουδέτερα. Ενδιαφέρον παρουσιάζει η φροντίδα για περιγραφή της μορφολογικής ποικιλίας που σχετίζεται με το ύφος και την κατάσταση επικοινωνίας.

2.14 Γενικές παρατηρήσεις

Στις παραπάνω ταξινομήσεις καταβάλλεται προσπάθεια για πληρότητα –σε ποικίλο βαθμό– με σύγχρονη μείωση του αριθμού των τιμών του χαρακτηριστικού της ΚΤ, δηλ. για επαρκή και οικονομική περιγραφή του κλιτικού συστήματος του ουσιαστικού.

Σε όλες τις προτάσεις (με εξαίρεση του Tonnet αλλά χωρίς αριθμητικά δεδομένα και της Χριστοφίδου (2003, βλ. παρακάτω 4.2), η οποία αναφέρεται σε παραγωγικές κλίσεις του ονόματος) δε λαμβάνεται υπόψη ο αριθμός των μελών κάθε ΚΤ, πράγμα σημαντικό, γιατί ο όγκος των μελών σε συνδυασμό με τη συχνότητα χρήσης επηρεάζει το σύστημα και οδηγεί σε αλλαγές που έχουν ως αποτέλεσμα αφενός την αύξηση των μελών των πολυπληθών και διαθέσιμων κλιτικών τάξεων και αφετέρου τη μείωση των μελών των ολιγομελών και μη διαθέσιμων τάξεων.

Αντιμετωπίζονται ισοπεδωτικά το συχνό και το μη συχνό, το διαθέσιμο και το μη διαθέσιμο.

Στη συντριπτική πλειονότητα των προτάσεων, με εξαίρεση τη Γραμματική των Joseph & Philippaki-Warbuton, τη Θωμαδάκη και τη Ράλλη (π.χ. 2003: 70), το φωνήεν πριν το -ς λ.χ. στο *φύλακας* δε θεωρείται τμήμα του θέματος αλλά του κλιτικού μορφήματος, π.χ. *φύλακ-ας*, με αποτέλεσμα να αυξάνει άσκοπα ο αριθμός των κλιτικών μορφημάτων.

3. Η πρότασή μας

3.1 Θεωρητικά

Η θεωρία των παραδειγματικών συναρτήσεων (Paradigm Function Morphology, Stump (2001)) δέχεται ως βασική μονάδα τη λέξη, ενώ το μόρφημα διαδραματίζει δευτερεύοντα ρόλο. Η λέξη συγκεντρώνει στο σώμα της τα μορφήματα, στα οποία προσδίδει συγκεκριμένη έννοια και λειτουργικότητα, και κάθε κλιτή λέξη είναι φορέας μορφοσυντακτικών ιδιοτήτων. Κατά τον Stump (2001: 32-33) τα κλιτικά παραδείγματα παίζουν κεντρικό ρόλο στην κλιτική μορφολογία μιας γλώσσας. Οι μορφολογικές εκφράσεις είναι 3 ειδών: ρίζες (roots), θέματα (stems) και λέξεις (words). Η ρίζα ενός λεξήματος είναι ο ερήμην τύπος του, απαλλαγμένος από κάθε στοιχείο κλίσης. Το θέμα είναι κάθε έκφραση στην οποία δυνάμει μπορούν να προστεθούν κλιτικοί εκθέτες (exponents), δηλ. τα κλιτικά επιθήματα. Ένα λέξημα έχει μόνο μία ρίζα, αλλά μπορεί να έχει πολλαπλά θέματα. Κατά τους Olivier Bonami και Gilles Boyé (2003, 2004, 2006, 2009, 2011), η μορφή του λεξήματος διαφοροποιείται σε θέματα αριθμημένα, τα οποία οργανώνονται σε έναν θεματικό χώρο, συστατικό στοιχείο του λεξήματος, από τα οποία παράγονται όλοι οι κλιτοί και παράγωγοι/σύνθετοι τύποι. Η κατανομή των θεμάτων αυτών διέπεται από ανστηρούς συσχετιστικούς κανόνες. Υπάρχουν 3 βασικά ζητήματα σχετικά με τα θέματα: α) ο τρόπος σχηματισμού του θέματος, β) η επιλογή το θέματος για κάθε γραμματική λέξη και γ) ο συσχετισμός των θεμάτων ενός λεξήματος.

Η υιοθέτηση της έννοιας του θεματικού χώρου έχει ως αποτέλεσμα κάθε κλιτός τύπος να μπορεί να επιλέγει ένα διαφορετικό θέμα, π.χ. όσον αφορά την κλίση του λεξήματος ΨΑΡΑΣ: η ονομαστική προκύπτει από το συσχετισμό του θέματος ΟΘ1¹⁰ *ψαρα-* με το κλιτικό -ς και η ονομαστική

¹⁰ Για να αποφευχθεί η σύγχυση ανάμεσα στα θέματα των διαφόρων θεματικών χώρων, προηγείται το όνομα της γραμματικής κατηγορίας. Έτσι το Ο σημαίνει ουσιαστικό, το οποίο παραλείπεται στη συνέχεια, γιατί όλη η εργασία αφορά τα ουσιαστικά.

πληθυντικού καθώς και το παράγωγο επίθετο¹¹ προκύπτουν από το συσχετισμό του θέματος Θ2β *ψαραδ-* με το κλιτικό *-ες* ή το επίθημα *-ικο(ς)*. Οι παραδειγματικές συναρτήσεις είναι στατικές συνθήκες σωστού σχηματισμού στα κελλιά. Έτσι προκύπτει το ότι τα κλιτικά είναι ίδια για όλα τα μέλη μίας ή πολλών ΚΤ, π.χ. *-ες* για τον πληθυντικό όλων των αρσενικών (εκτός των σε *-ος*) και όχι για άλλα αρσενικά ουσιαστικά *-ες* και για άλλα *-δες*.

Η έννοια του θεματικού χώρου επιτρέπει μεταξύ άλλων (Boyé 2011) αφενός να συλλάβουμε την απόλυτη αμοιβαία προβλεπτότητα ορισμένων τύπων ενός κλιτικού παραδείγματος, στο βαθμό που οι τύποι αυτοί για όλα τα λεξήματα βασίζονται στον ίδιο τύπο θέματος, π.χ. η γενική πληθυντικού για όλα τα αρσενικά βασίζεται στο Θ2 (α ή β) λ.χ. *φυλάκων, ανθρώπων, ψαράδων*, και αφετέρου να περιγράψουμε ενοποιητικά την κλιτική και παραγωγική μορφολογία.

Μια άλλη έννοια της θεωρίας αυτής είναι η έννοια του δέντρου των ιεραρχικών θεματικών εξαρτήσεων (slot dependencies), σύμφωνα με την οποία από ένα κύριο θέμα μπορούν να παραχθούν τα άλλα θέματα, λ.χ. από το θέμα *ψαρα-* παράγεται το θέμα *ψαραδ-*. Υπάρχει σύστημα αμοιβαίων αντιστοιχιών που επιτρέπει να συμπληρώνεται το σύνολο του θεματικού χώρου με βάση κάποιο κυρίαρχο θέμα.

Τέλος θεωρούμε χρήσιμη την έννοια της διαθεσιμότητας (Corbin 1987), που τη μεταφέρουμε από τη Μορφολογία Παραγωγής στην Κλιτική Μορφολογία. Διαθέσιμες διαδικασίες είναι εκείνες όπου οι μη μαρτυρημένες κατασκευασμένες λέξεις, που όμως σέβονται τους γλωσσικούς περιορισμούς, είναι τυχαία κενά. Μη διαθέσιμες είναι οι διαδικασίες που περιγράφουν μόνο μαρτυρημένες κατασκευασμένες λέξεις. Αναλογικά διαθέσιμες είναι οι ΚΤ που ενσωματώνουν νέα μέλη, είτε μέσω της νεολογίας είτε γενικότερα μέσω της γλωσσικής αλλαγής. Η διαθεσιμότητα είναι γλωσσικής φύσης και στηρίζεται στη γλωσσική ικανότητα. Επίσης διαφέρει από τη συχνότητα. Είναι δυνατό μια διαδικασία που δεν έχει υψηλή συχνότητα να είναι διαθέσιμη. Ή και αντίστροφα μια διαδικασία μπορεί να είναι συχνή αλλά όχι διαθέσιμη. Για μας η ΚΤ των αρσενικών σε *-ος* δεν είναι διαθέσιμη, περιλαμβάνει ωστόσο πολλά συχνόχρηστα ουσιαστικά. Χρήσιμες πληροφορίες για τις διαθέσιμες δομές παρέχουν οι παρατηρήσεις για τη δυναμική των γλωσσών σε συγχρονικό επίπεδο και ιδιαίτερα η μελέτη των φαινομένων νεολογίας (βλ. Αναστασιάδη-Συμεωνίδη 1986).

3.2 Κλιτικές τάξεις (ΚΤ)

Με βάση τα κλιτικά μορφήματα που εφαρμόζονται στο θέμα, διακρίνουμε 6 ΚΤ, που δε συμπίπτουν με προηγούμενες κατηγοριοποιήσεις. Οι ΚΤ θα ήταν 7, εάν υπολογίζαμε και τα άκλιτα.

3.2.1 Κλιτικός θεματικός χώρος

	Θέμα 1	Θέμα 2	Θέμα 3	Θέμα 4	συχνότητα τύπου ¹²
	ΟΕ, ΑΕ, ΚΕ	ΓΕ, ΟΠ, ΓΠ, ΑΠ, ΚΠ	ΓΕ	ΚΕ	
ΚΤ 1,2	Θ1	Θ2	Θ3=Θ2	-	46.000
ΚΤ 3	Θ1	Θ2	-	Θ4=Θ2	9.000
ΚΤ 4,5,6	Θ1	Θ2	-	-	27.000

Ο = ονομαστική, Α = αιτιατική, Κ = κλητική, Γ = γενική, Ε = ενικός, Π = πληθυντικός.

3.2.2 Επιλογή του θέματος (X)

Είναι γενικώς αποδεκτό ότι στην κλητική το ουσιαστικό εμφανίζεται στην πρωτοτυπική του μορφή, δηλ. το θέμα εμφανίζεται γυμνό, κάτι που συνταιριάζεται με τη λειτουργία της πτώσης αυτής, όπου το

¹¹ Το παράγωγο επίθετο είναι προϊόν του συσχετιστικού Κανόνα Κατασκευής Λέξεων/Λεξημάτων, που παράγει επίθετα από βάση ουσιαστικό (Corbin 1987). Η θεωρία των Bonami & Boyé συμπληρώνει το θεωρητικό πλαίσιο της Corbin ως εξής: ο κάθε ΚΚΛ πρέπει να δηλώνει ποια θέματα του θεματικού χώρου της βάσης χρησιμοποιεί και ποια θέματα του θεματικού χώρου του παραγόμενου κατασκευάζει, π.χ. *ψάρι* → *ψαρ-ικός* (θέμα *ψαρ-*) αλλά *ψαράς* → *ψαράδικος* (θέμα *ψαραδ-*).

¹² Τα αριθμητικά δεδομένα προέρχονται από το *Αντίστροφο Λεξικό της Νέας Ελληνικής* (2002).

ουσιαστικό «δεν κάνει τίποτε άλλο από το να *καλεί* κάτι με το όνομά του» (Κλαίρης & Μπαμπινιώτης 1996: 50).¹³ Ωστόσο η παρουσία της ΚΤ των ουσιαστικών σε -ος δεν μας επιτρέπει να επιλέξουμε την κλητική, λόγω των τύπων σε -ε, που παρουσιάζουν δηλ. αλλαγή στο θεματικό φωνήεν, π.χ. *φίλε!* Βέβαια ο σχηματισμός της κλητικής της τάξης αυτής δεν είναι ενιαίος, αφού συναντούμε κύρια ονόματα με κλητική σε -ο, δηλ. εναρμονισμένα με τον τρόπο σχηματισμού της κλητικής σε όλες τις υπόλοιπες ΚΤ, π.χ. *Νίκο!* Λόγω της κλητικής σε -ε απορρίφθηκε η κλητική ως η πτώση για την παραγωγή του θέματος 1. Επίσης απορρίφθηκε η ονομαστική, επειδή είναι πιο περίπλοκη από την αιτιατική, αφού στα αρσενικά προστίθεται το -ς. Έτσι τελικά προτείνεται η αιτιατική ως η πτώση που θα μας δώσει το θέμα 1.¹⁴

3.2.3 Παραγωγή των θεμάτων

Τα θέματα παράγονται με 3 τρόπους (Α, Β, Γ):

	Τρόπος Α	Τρόπος Β	Τρόπος Γ
Θέμα 1 (αιτ./εν.)	X+φωνήεν	X+i	X+η ¹⁵
Θέμα 2α	X	X	X
Θέμα 2β	X+φωνήεν+δ/τ	X+j	X+ε

Όπου X = θέμα του λεξήματος
φωνήεν: το φωνήεν του Θέματος 1 και του Θέματος 2β είναι πάντα το ίδιο στο κλιτικό παράδειγμα, δηλ. παραμένει σταθερό. Τα φωνήεντα είναι *α/η/ε/ου/ο*.

Δεν προβλέπονται μηδενικά μορφήματα.

Το Θέμα 2α προέρχεται από το Θέμα 1 μετά την αφαίρεση του τελικού φωνήεντος.

Το Θέμα 2β προέρχεται από το Θέμα 1 με την προσθήκη ενός οδοντικού: -δ- για τα αρσενικά και θηλυκά, και -τ- για τα ουδέτερα.

Από τους 3 τρόπους παραγωγής των θεμάτων, ο Α και ο Β είναι οι πρωτοτυπικοί,¹⁶ ενώ ο Γ είναι λιγότερο πρωτοτυπικός, γιατί αφορά περιορισμένο αριθμό αρσενικών και θηλυκών ουσιαστικών όπως *πρέσβης, πόλη, δύναμη*, αλλά και όλα τα παράγωγα μεταρρηματικά θηλυκά ουσιαστικά σε -ση/-ξη/-ψη.

3.2.4 Εφαρμογή στα ουσιαστικά της ΝΕ

ΚΤ 1: Θέμα 1 *φυλακα, αγροτη, τομεα, ψαρα, μαναβη, παππου, καφε, πρεσβη*

Θέμα 2α *φυλακ, αγροτ, τομε, ψαρ, μαναβ, καφ*¹⁷

Θέμα 2β *ψαραδ, μαναβηδ, παππουδ, καφεδ, πρεσβε*

ΚΤ 2: Θέμα 1 *θαλασσα, αναγκη, μαμα, αλεπου, δυναμη*

Θέμα 2α *θαλασσ, αναγκ, μαμ, αλεπ, δυναμ*

Θέμα 2β *μαμαδ, αλεπουδ, δυναμε*

ΚΤ 3: Θέμα 1 *ανθρωπο*

Θέμα 2α *ανθρωπ*

Θέμα 2β *ανθρωπε*

ΚΤ 4: Θέμα 1 *βουτυρο, χωραφι*

Θέμα 2α *βουτυρ, χωραφ*¹⁸

Θέμα 2β *χωραφj*

¹³ Για μια πρωτότυπη περιγραφή του συντακτικού και πραγματολογικού ρόλου της κλητικής στη ΝΕ βλ. Σταύρου (2009) και για την ΑΕ (Kakarikos 2011).

¹⁴ Ας μη λησμονούμε και το βασικό ρόλο που ιστορικά έπαιξε η αιτιατική στη διαμόρφωση της ΝΕ ονομαστικής.

¹⁵ Ειδικά για την ΚΤ 2 όπου ανήκουν τα θηλυκά ουσιαστικά σε -ση/-ξη/-ψη, προβλέπεται εκτός από το Θ1 σε η π.χ. *φωση* και Θ1β σε ι π.χ. *φωσι*, λ.χ. στο *φωσιολατρικός*. Για το λόγο αυτό το Θ1 σε η είναι στην ουσία Θ1α για την κατηγορία αυτή των θηλυκών ουσιαστικών.

¹⁶ Ο Β τρόπος αφορά μόνο τα ουδέτερα σε -ι.

¹⁷ Το θέμα *καφ*- δεν χρησιμοποιείται στην κλίση αλλά στη σύνθεση, π.χ. *καφόμεπρικο*.

¹⁸ Το θέμα αυτό δε χρησιμοποιείται στην κλίση αλλά στην παραγωγή, π.χ. *χωραφ-άκι*.

ΚΤ 5: Θέμα 1 *πραγμα, περας οζυ*
 Θέμα 2α *οξ*
 Θέμα 2β *πραγματ, περατ, οξε*

ΚΤ 6 Θέμα 1 *εδαφος*
 Θέμα 2α *εδαφ*
 Θέμα 2β

3.3 Πλεονεκτήματα της ανάλυσης αυτής

Η ανάλυση αυτή πλεονεκτεί έναντι των άλλων ως προς τον ενοποιητικό χαρακτήρα της σχετικά με τις μορφολογικές διαδικασίες και ιδίως ως προς τον προβλεπτικό χαρακτήρα της.

3.3.1 Ενοποιημένη περιγραφή των παραγόμενων τύπων (κλιτών, παράγωγων, σύνθετων)

Το θέμα 1 *αγροτ-* παράγει το θέμα 2α *αγροτ-*, που αποτελεί τη βάση του παραγώγου *αγροτ-ιά* (Ευθυμίου 1999), το θέμα 1 *ψαρα-* παράγει το θέμα 2β *ψαραδ-*, που αποτελεί τη βάση του παραγώγου *ψαράδικος*. Το θέμα 1 *καφε-* παράγει το θέμα 2α *καφ-* και 2β *καφεδ-*, που αποτελεί τη βάση για το παράγωγο *καφεδάκι*. Το θέμα 1 *μαναβη-* παράγει το κλιτικό θέμα 2β *μαναβηδ-* και το κλιτικό θέμα 2α *μαναβ-*, που αποτελεί τη βάση του παραγώγου *μαναβικός/μαναβική, η*. Το Θ1α *μεταφραση* παράγει το Θ2α *μεταφρασ-* και το Θ2β *μεταφρασε-*, καθώς και το Θ1β *μεταφρασι*, που αποτελούν βάση παραγώγων και συνθέτων: *μεταφρασ-ούλα, μεταφρασε-ο-λογία, μεταφρασι-ο-λογία*.

Έτσι το ουσιαστικό *ψάρι* δίνει το Θ2α *ψαρ-* που αποτελεί τη βάση πάνω στην οποία με την εφαρμογή του επιθήματος *-ά(ς)* παράγεται το παράγωγο *ψαρά(ς)*, το οποίο έχει ως θέμα 1 τον τύπο *ψαρα-*, ως θέμα 2α τον τύπο *ψαρ-* πάνω στον οποίο με την εφαρμογή του κλιτικού *-ού* παράγεται ο τύπος του θηλυκού *ψαρού*.

→ [[ψαρ-]_{Ουσ} (-ικό(ς))_{Επ.}]_Ε
 [ψάρι] → [[ψαρ-]_{Ουσ} (-ά(ς))_{Επ.}]_{Ε/ Ουσ}
 ↓
 ▼ Θ1 ψαρα-
 Θ2α ψαρ- → ψαρού¹⁹
 Θ2β ψαραδ- → ψαράδικος

3.3.2 Υψηλός βαθμός προβλεπτότητας

1. Πώς προβλέπεται αν ένα ουσιαστικό έχει ένα Θ2α (X) ή ένα Θ2β (X+φωνήεν+δ/τ); (τρόπος Α)²⁰

Τα [+/-λόγια] επιθήματα μαζί με τη βάση τους σχηματίζουν τύπο με Θ2α, ενώ τα [-λόγια] επιθήματα μαζί με τη βάση τους σχηματίζουν τύπο με Θ2β. Κατά γενικό κανόνα οι απλές λέξεις έχουν ένα Θ2α. Ενώ τα προσαρμοσμένα άμεσα δάνεια, που είναι [-λόγια], έχουν ένα Θ2β. Επίσης, αν εξετάσουμε τα επιθήματα καθώς και τα κλιτικά για το σχηματισμό του θηλυκού ως προς το χαρακτηριστικό [+/-λόγιο], παρατηρούμε ότι επιβεβαιώνεται η κατανομή των θεμάτων 2α και 2β.

Επιθήματα	[+/-λόγιο]	[-λόγιο]
-(ι)άτη(ς)	2α	
-(ι)ώτη(ς)	2α	
-ίτη(ς)	2α	
-τη(ς)	2α	
-μα		2β
-ιμο		2β
-ά(ς)		2β
-(α/ι)τζή(ς)		2β

¹⁹ Το σύμβολο (→) χρησιμοποιείται για διαδικασίες παραγωγής και το σύμβολο (→►) για διαδικασίες κλίσης.

²⁰ Βλ. 3.2.3.

-αλή(ς)		2β
-ακλά(ς)		2β
-(ι)άρη(ς)		2β
-ιέρη(ς)		2β
-ούλη(ς)		2β

Για το σχηματισμό του θηλυκού

Επιθήματα/κλιτικά	[+/-λόγιο]	[-λόγιο]
-α	2α	
-ισσα	2α	
-τρια	2α	
-τρα ²¹	2α	
-ιδα	2α	
-αίνα	2α	
-ού ²²		2β

2. Πώς προβλέπεται αν τα ουσιαστικά σε -α/-η έχουν ένα Θ2α (X) ή ένα Θ2β (Xε); (τρόπος Γ)²³
Ένα παράγωγο ουσιαστικό με το επίθημα -ση/-ξη/-ψη έχει κατά κανόνα ένα Θ2β (τρόπος Γ), δηλ. σε -ε. Οι απλές λέξεις όπως *πόλη, δύναμη* είναι ελάχιστες.

Επίθημα	[+/-λόγιο]	[-λόγιο]
-ση/-ξη/-ψη	2β	

3. Πώς προβλέπεται το Θ των παραγώγων σε -ικο;²⁴

Το επίθημα -ικ(ος) εφαρμόζεται σε Θ2α ή Θ2β με κριτήριο τη σταθερότητα του τόνου (βλ. και Θωμαδάκη 1994: 180).

Θ1	Θ2α	Θ2β		Παράγωγα με το Θ2α	Παράγωγα με το Θ2β	Μη γραμματικοί σχηματισμοί
ψαρα	ψαρ	ψαραδ	→		ψαράδ-ικο	*ψάρ-ικο
μαναβη	μαναβ	μαναβηδ	→	μανάβ-ικο		*μαναβίδ-ικο
πεισματαρη	πεισματαρ	πεισματαρηδ	→	πεισματάρ-ικο		*πεισματαρίδ-ικο
γλυκατζη	γλυκατζ	γλυκατζηδ	→		γλυκατζίδ-ικο	*γλυκατζ-ικο
μουστακαλη	μουστακαλ	μουστακαληδ	→		μουστακαλίδ-ικο	*μουστακάλ-ικο
φωνακλα	φωνακλ	φωνακλαδ	→		φωνακλάδ-ικο	*φονάκλ-ικο
ταξιδιαρη	ταξιδιαρ	ταξιδιαρηδ	→	ταξιδιάρ-ικο		*ταξιδιαρίδ-ικο

²¹ Το -τρα αποτελεί το [-λόγιο] τύπο του -τρια, όπως προκύπτει από [-λόγιους] τύπους θεμάτων στα οποία εφαρμόζεται μόνο ο τύπος -τρα, π.χ. *περέτρα – υπηρέτρια, μαζώχτρα, βυζάχτρα*. Όταν το θέμα δεν διαφοροποιείται ως προς το χαρακτηριστικό [+/-λόγιο], το -τρα εμφανίζεται παράλληλα με το θηλ. σε -τρια π.χ. *οδηγήτρια/οδηγήτρα* ή αποκλειστικά ως τύπος θηλυκού στην περίπτωση λογοτεχνικής χρήσης ή συνυποδηλωτικής, συναισθηματικής σημασίας, π.χ. *αρπάχτρα, γλείφτρα, καρδιοκάφτρα, κλέφτρα, μαγεύτρα, πλανεύτρα, ράφτρα*, διάκριση που δεν γίνεται στο αρσενικό σε -της π.χ. *ράφτης*. Ωστόσο ακολουθεί την ίδια επιλογή θέματος με το -τρια.

²² Δηλ. το -ού εφαρμόζεται σε Θ2α (ψαρ-) αλλά μετά τη διαδικασία αυτή σχηματίζει Θ2β (ψαρουδ-).

²³ Βλ. 3.2.3.

²⁴ Πρόκειται για κατασκευή ουσιαστικών μέσω της μετατροπής (βλ. Αναστασιάδη-Συμεωνίδη 1997) όπου βάση είναι το παράγωγο μετονομαστικό επίθετο με το επίθημα -ικο(ς), π.χ. *ψαρά(ς)ουσ.* → *ψαράδικο(ς)*_{επίθετο} → *ψαράδικο*_{ουσιαστικό}

4. Συμπεράσματα

4.1 Συνθετότητα του συστήματος

Υποστηρίζουμε ότι το πρωτοτυπικό σύστημα κλίσης των ουσιαστικών της ΝΕ είναι απλό. Όμως τι ακριβώς σημαίνει «το σύστημα είναι απλό»; Τι εννοείται με τον όρο συνθετότητα ενός κλιτικού συστήματος; Ο βαθμός συνθετότητας μπορεί να μετρηθεί;

Διαισθητικά οι ομιλητές θεωρούν ότι το ονοματικό κλιτικό σύστημα της ΑΕ ήταν πιο σύνθετο από της ΝΕ, που θεωρείται πιο απλό. Ωστόσο η συνθετότητα είναι πολύπλευρη και για τη μέτρησή της απαιτείται ειδική θεωρία. Ο βαθμός συνθετότητας θα μπορούσε να προκύψει από το συνυπολογισμό του μεγέθους του κλιτικού παραδείγματος, τον αριθμό των κλιτικών τύπων κάθε λεξήματος και τη σχέση τους με τον αριθμό των γραμματικών λέξεων που ανήκουν στο ίδιο λέξημα, τον αριθμό και τη δομή των ΚΤ, τον αριθμό των ανώμαλων τύπων, τις σχέσεις προβλεπτότητας ανάμεσα στις γραμματικές λέξεις του ίδιου λεξήματος κτλ. Ωστόσο το ζήτημα αυτό δε θα μας απασχολήσει στη φάση αυτή.

4.2 Πρωτοτυπικό σύστημα κλίσης

Τι περιλαμβάνει το ΝΕ πρωτοτυπικό σύστημα κλίσης των ουσιαστικών;

- 1) Τα δικατάληκτα (έναντι των τρικαταλήκτων)
- 2) Στον ενικό: -ς στην ονομαστική των αρσενικών και στη γενική των θηλυκών. Παντού αλλού ο ίδιος τύπος ονομ./αιτ./κλιτ.
- 3) Στον πληθυντικό:
 - ων: γενική πληθυντικού
 - ες: αρσενικά/θηλυκά ονομ./αιτ./κλιτ.
 - α: ουδέτερα ονομ./αιτ./κλιτ.

ΚΛΙΤΙΚΕΣ ΤΑΣΕΙΣ

	1	2	3	4	5	6
ΟΕ	ς					
ΑΕ						
ΚΕ			ο/ε			
ΓΕ		ς/ως	ου	ου	ος	ους
ΟΠ	ες	ες	οι	α	α	η
ΑΠ	ες	ες	ους	α	α	η
ΚΠ	ες	ες	οι	α	α	η
ΓΠ	ων	ων	ων	ων	ων	ων
ουσιαστικά	13.000	33.000	9.000	20.000	6.000	200

Η πρότασή μας αυτή για το τι ανήκει στο πρωτοτυπικό κλιτικό σύστημα θα ελεγχθεί με επιχειρήματα από έξι χώρους:

- α) από τον τρόπο συμμόρφωσης των δανείων στη ΝΕ,
- β) από τα ληκτικά τεμάχια των νεολογισμών που είναι ουσιαστικά κλιτά,
- γ) από την εσωτερική αλλαγή στο κλιτικό σύστημα, δηλ. τη μετακίνηση μελών από μια ΚΤ σε άλλη,
- δ) από τις προτιμώμενες ΚΤ από τα επιθήματα,
- ε) από τη γλωσσική κατάκτηση και

στ) από την απόκτηση της ΝΕ ως δευτερης/ξένης γλώσσας.

α-β) Η Χριστοφίδου (2003: 114) πολύ σωστά διακρίνει πρότυπα που δεν εμφανίζονται σε δάνεια και νεολογισμούς όπως τα θηλυκά σε -ος και τα ουδέτερα σε -ο,²⁵ -μα και -ος. Θεωρεί παραγωγικές κλίσεις για τα αρσενικά τις καταλήξεις -ας (και δευτερευόντως -ος), για τα θηλυκά τις καταλήξεις -α (και -η) και για τα ουδέτερα τις καταλήξεις -ι (και -ο).

Πράγματι οι νεολογισμοί σε -ο που είναι κλιτά ουδέτερα ουσιαστικά από το Αρχείο νεολογισμών που διαθέτουμε είτε είναι σύνθετα με β' συνθετικό ήδη προϋπάρχον, π.χ. *βιοπορτρέτο*, είτε είναι παράγωγα με προϋπάρχον επίθημα π.χ. *ψυχοτρόνιο*²⁶, *πρεκαριάτο*, *κογκνιταριάτο* (Αναστασιάδη-Συμεωνίδη & Νικολάου 2011). Διαφορετικά επιλέγεται το θέμα σε -ι.

γ) Τα αρσενικά σε -ος εγκαταλείπουν αυτή την ΚΤ τάξη που δεν είναι πια διαθέσιμη και εντάσσονται στην ΚΤ των σε -ας, π.χ. *έμπορος* → *έμπορας*, *μάγειρος* → *μάγειρας*²⁷ (Χριστοφίδου 2003: 112). Τα θηλυκά σε -ος τείνουν να υιοθετήσουν το αρσενικό γένος, π.χ. *ψήφος*, *άμμος* (βλ. Αναστασιάδη-Συμεωνίδη & Μητσιάκη υπό έκδοση) ή παραμένουν θηλυκά αλλά αποβάλλουν το -ς π.χ. *η άμμο*, *η Χιο* ή τέλος μετατρέπονται σε ουδέτερα σε -ο, π.χ. *αλφάβητο*, *ύπαιθρο* (βλ. Αναστασιάδη-Συμεωνίδη & Χειλά-Μαρκοπούλου 2003: 28-29).

δ) Τα επιθήματα συνδυάζονται στα δεξιά τους με κλιτικά του πρωτοτυπικού συστήματος (βλ. και Χριστοφίδου 2003: 105, 113).

ε) Τα παιδιά κατακτούν κατά προτεραιότητα τις παραγωγικότερες καταλήξεις, οι οποίες στην πρότασή μας αντιστοιχούν για τα αρσενικά στην ΚΤ1, για τα θηλυκά στην ΚΤ2 και για τα ουδέτερα στην ΚΤ4 (Χριστοφίδου 2003: 126). Ειδικότερα τα αρσενικά σε -ος (ΚΤ3), κατά τη Χριστοφίδου (2003: 131), ανήκουν σε παραγωγική κλίση με σημάδια υποχώρησης, αν και παρατηρείται αφενός καθυστερημένη κατάκτησή τους και αφετέρου μετακίνηση των μελών της κατηγορίας αυτής προς την παραγωγική ΚΤ1. Το ερώτημά μας είναι πώς ορίζεται η έννοια της παραγωγικότητας προκειμένου για τη συγκεκριμένη ΚΤ; Η πρότασή μας για την ΚΤ των ουσιαστικών σε -ος είναι ότι πρόκειται για κατηγορία μη διαθέσιμη πλέον. Αυτή η αρνητική έκβαση για την άλλοτε κραταιά ΚΤ δεν γίνεται άμεσα αντιληπτή λόγω της υψηλής συχνότητας χρήσης των ουσιαστικών που ανήκουν εδώ.

στ) Σχετικά με τα γραμματικά κλιτικά μορφήματα, δύο είναι οι βασικές παρατηρήσεις που αφορούν το σύνολο του δείγματος από γραπτά αλλοδαπών μαθητών ανεξαρτήτως της πρώτης γλώσσας (Γ1) τους (Αναστασιάδη-Συμεωνίδη, Βλέτση, Μητσιάκη, Μποζονέλος, Χούμα 2010): α) εντοπίζεται υπεργενίκευση του μορφήματος -ες για το σχηματισμό του πληθυντικού σε όλες τις ΚΤ, π.χ. *θρανίες*, *παράθρηες*, *οι τείχες* (αντί *οι τοίχοι*) και β) προστίθεται σε ληκτική θέση το γραμματικό μόρφωμα -α (+ουδέτερο, +πληθυντικός) σε άκλιτες λέξεις, π.χ. *στα τράμα*, πιθανόν για λόγους συμμόρφωσης στην πρωτοτυπική συλλαβή²⁸ της ΝΕ και στο ασημάδευτο γένος. Επίσης ένταξη στην πρωτοτυπική ΚΤ των ουδετέρων σε -ο, π.χ. *στο δάσο* (αντί *στο δάσος*), γιατί τα ουδέτερα σε -ος δεν ανήκουν στο πρωτοτυπικό σύστημα και η ΚΤ τους δεν είναι διαθέσιμη. Άλλωστε είναι τα μόνα που παρουσιάζουν τριπλές μετακινήσεις στον τόνο: *μέγεθος-μεγέθους-μεγεθών* (Ρεβυθιάδου 1999). Ωστόσο ομαλότητα, διαθεσιμότητα και συχνότητα δεν συνιστούν τα αναγκαία κριτήρια για την αναγνώριση του πρωτοτύπου (Legallois & Jacques Francois 2011 : 52).

4.3 Δύο βασικά χαρακτηριστικά

Η ΝΕ διαθέτει 2 βασικά χαρακτηριστικά, όπως διαγράφονται από την ανάλυση που προηγήθηκε: επιζητεί τη σαφή διάκριση των κατηγοριών και την οικονομία.

4.3.1 Σαφής διάκριση κατηγοριών

Η ελληνική είτε στην ΑΕ φάση της είτε στη ΝΕ συγκαταλέγεται μεταξύ των γλωσσών με πλούσιο κλιτικό σύστημα. Ωστόσο μια σημαντική διαφορά ανάμεσα στις δύο είναι ότι η ΝΕ αναζητεί τη σαφή διάκριση των κατηγοριών, λ.χ. ουσιαστικό από επίθετο, ενικός από πληθυντικός, αρσενικό από θηλυκό

²⁵ Τα περισσότερα δάνεια εντάσσονται ως ουδέτερα με την κατάληξη -ι και σπανιότερα με την κατάληξη -ο, π.χ. τουρκικό *meltem* > *μελτέμι* (Χριστοφίδου 2003: 105).

²⁶ Για το επίθημα -όνιο βλ. Αναστασιάδη-Συμεωνίδη 2009.

²⁷ Ωστόσο ο *γείτονας* – πληθ. *γείτονες* αλλά και *γειτόνοι/γειτόνους*. (Ευχαριστώ τη συνάδελφο Μ. Μαργαρίτη-Ρόγκα για την επισημάνση αυτή).

²⁸ Σύμφωνα και Φωνήεν.

αλλά ιδίως αρσενικό και θηλυκό από ουδέτερο.²⁹ Διαβλέπουμε μια τάση της ΝΕ να παίζει με ανοιχτά χαρτιά: διαφοροποιεί σαφώς τα αρσενικά από τα θηλυκά, και τα δύο μαζί από τα ουδέτερα και ιδίως στον πληθυντικό. Πβ. την κοινή κατάληξη αρσενικών και θηλυκών στον πληθυντικό -ες σε αντίθεση με το -α των ουδετέρων, το -δ- στα ανισοσύλλαβα σε αντίθεση με τα ουδέτερα που εμφανίζουν το -τ- π.χ. *μπαμπάδες-μαμάδες* αλλά *χρώματα*, την ταυτότητα του θεματικού φωνήεντος στα αρσενικά και θηλυκά: -α, -η, -ο, -ε και -ού, π.χ. *μπαμπάς/μαμά*, *ναύτης/νύφη*, *άνθρωπος/άμμος*, *μπουφές/νενέ*, *παπούς/αλεπού*, σε αντίθεση με τα ουδέτερα που το θεματικό τους φωνήεν είναι -α, -ι, -ο, π.χ. *στόμα*, *παιδί*, *νερό*.

Η θέση μας αυτή για τη σαφή διάκριση των κατηγοριών υποστηρίζεται τόσο από το γεγονός ότι η κλίση των ουσιαστικών σε -ος δεν είναι πια διαθέσιμη αλλά αποκτά αποκλειστικότητα για τα επίθετα, όσο και από την ευρύτατη εμφάνιση του ταξικού σηματοδότη³⁰ στο τέρμα των λέξεων, ρόλος του οποίου είναι να ενσωματώσει τις λεξικές μονάδες στην τάξη όπου ανήκουν μορφολογικά ή σημασιολογικά, π.χ. *σέξουαλ* → *σεξουαλ-ικός*, *κλότσος* → *κλοτσ-ιά*, *τοπ* → *τοπάκι*. Επίσης το τελικό -ς αποτελεί δείκτη αρσενικότητας και τα λίγα θηλ. ή ουδ. σε -ς προσπαθούν να επιβιώσουν σε ένα αφιλόξενο πλέον γι' αυτά περιβάλλον π.χ. *η ψήφος* → *ο ψήφος* (Αναστασιάδη-Συμεωνίδη & Μητσιάκη υπό έκδοση). Διότι τελικά το τέρμα των λέξεων έχει βαρύνουσα σημασία και συμβάλλει απόλυτα στον καθορισμό της γλώσσας που μιλάμε, πβ. το γαλλοφανές λόγω τερμάτων σύγχρονο περιπαιχτικό κείμενο της ΝΕ:

Μαντμαζέλ, κοινοβουλευτισιόν χοντροκλεινιόν γκαραντί,
χρηματιστίκ, βατοπεδουάρ, ολυμπιάντ, ασφαλιστίκ κασέ
Τώρα, μέσα στο μαιζόν εγκλειστίκ, τρε μπατίρ, καταστασιόν απελπιστίκ

Έτσι ερμηνεύουμε και τη συμμόρφωση των δανείων στο μορφολογικό σύστημα μιας γλώσσας, αφού αρκεί το τέρμα να είναι σύμφωνο με το ΝΕ σύστημα για να είναι ελληνοφανής η λέξη. Επιπλέον επιχείρημα για το σημαντικό ρόλο του τέρματος των λέξεων αντλούμε από την κατευθυντικότητα της συλλαβοποίησης για την ελληνική, που είναι από δεξιά προς τα αριστερά (Karra 1995). Δηλαδή, σε μια ακολουθία φθόγγων αρχίζει ο σχηματισμός της συλλαβικής δομής (πυρήνας και μεγιστοποίηση της έμβωσης) από το τελευταίο δεξιό φωνήεν και συνεχίζεται με το σχηματισμό της επόμενης συλλαβικής δομής προς τα αριστερά.

Επίσης ο ανισοσύλλαβος πληθυντικός, που αποτελεί κανόνα για τη ΝΕ, διαφοροποιείται από τον ενικό με τη μέγιστη εικονικότητα, επειδή ενισχύεται με μία επιπλέον συλλαβή (Mayerthaler 1981 : 23 από Kilani-Schoch 1988 : 99). Ακόμη η ανισοσυλλαβία συμβάλλει στη διατήρηση του θεματικού φωνήεντος και του τόνου. Γενικά τα ισοσύλλαβα ουσιαστικά που διαθέτουμε είτε είναι κληρονομημένα λ.χ. *άνθρωπος*, *χαρά*, είτε είναι κατασκευασμένες λέξεις (παράγωγα, σύνθετα) π.χ. *σφουγγαρόπανο*, *σιδηρόδρομος*. Για μας δεν είναι τυχαίο το ότι στη ΝΕ όλα τα επιθήματα κατασκευής αρσενικών ουσιαστικών που δεν αποτελούν κληρονομία από την ΑΕ όπως είναι το -της σχηματίζουν ανισοσύλλαβο πληθυντικό, π.χ. -άς (*γαλατάς*), -τζής (*παλιατζής*), -λής (*μερακλής*), -άρης/-ιέρης (*βαρκάρης*, *τιμονιέρης*), -ιάρης (*ψειριάρης*), -άκις (*γυαλάκις*).³¹ Αξίζει να σημειωθεί ότι η ανισοσυλλαβία αφορά το αρσενικό και επιτρέπει την εμφανή διάκριση από τον αντίστοιχο τύπο του θηλυκού, π.χ. *ζηλιάρης/ζηλιάρηδες* αλλά *ζηλιάρα/ζηλιάρες*.

Επίσης στις νεότερες κλιτικές τάξεις ο πληθυντικός σχηματίζεται ανισοσύλλαβα π.χ. αρσενικά σε -ές (*καφές*, *καναπές*), σε -ούς (*παπούς*), σε -ης (*μανάβης*) και θηλυκά σε -έ (*νενέ*), σε -ού (*αλεπού*).

Επιπλέον τα νεότερα ουσιαστικά, ακόμη και αν το σύστημα διαθέτει κατάληξη, δημιουργούν ανισοσύλλαβο πληθυντικό, π.χ. αρσ. *φύλακας/φύλακες* (ΑΕ *φύλαξ*), αλλά *μπάρμπα/μπαρμπάδες* και θηλ. *χαρά/χαρές* (ΑΕ *χαρά*) αλλά *μαμά/μαμάδες*.

Τέλος υπάρχουν κληρονομημένα ή λόγια ισοσύλλαβα που δημιουργούν και ανισοσύλλαβο πληθυντικό με [-λόγιο] χαρακτήρα, π.χ. *καθηγητής/καθηγητές* και *καθηγητάδες*, *δεσπότης/δεσπότες* και *δεσποτάδες*, *μάντες/μάντεις* και *μάντηδες*, *Καππαδόκης/Καππαδόκες* και *Καππαδόκηδες* – *αδερφές/αδερφάδες*, *νύφες/νυφάδες* – *άλογα/αλόγατα*, *πρόστιμο/πρόστιμα* και *προστίματα*.³² Δηλ. η κατεύθυνση για το σχηματισμό του πληθυντικού είναι από την ισοσυλλαβία στην ανισοσυλλαβία, γιατί είναι πιο εικονική.

²⁹ Π.χ. στην ΑΕ δεν υπάρχουν ουσιαστικά στα οποία η ανισοσυλλαβία διαφοροποιεί τον ενικό από τον πληθυντικό, δεν είναι συχνά δυνατή η πρόβλεψη του γένους από το κλιτικό μόρφημα. Βλ. και Θωμαδάκη (1994: 138).

³⁰ Βλ. Corbin (1987) και Αναστασιάδη-Συμεωνίδη & Μασούρα (2009).

³¹ Με εξαίρεση το -ίστας, που ίσως αντιγράφει το -ιστής.

³² Κατά τα παράγωγα σε -μο, ενώ εδώ δεν μετέχει το επίθημα -(σ)ιμο, γιατί το -ιμ αποτελεί τεμάχιο του θέματος.

4.3.2 Οικονομία

Το ΝΕ ονομαστικό κλιτικό σύστημα επιζητεί τη σαφή διάκριση των κατηγοριών αλλά με λιτό τρόπο, δηλ. διατηρώντας τις διακρίσεις που θεωρούνται απαραίτητες, λ.χ. ενικός-πληθυντικός, αρσενικό-θηλυκό-ουδέτερο, ορθές-πλάγιες πτώσεις³³ για συντακτικούς λόγους. Άλλες διακρίσεις δε θεωρούνται απαραίτητες και συνεπώς βασιλεύει ο συγκρητισμός. Υπό το πρίσμα αυτό τα αρσενικά σε -ος διαθέτουν περιττή πολυτέλεια διακρίνοντας 4 διαφορετικούς κλιτικούς τύπους στον κάθε αριθμό, χωρίς επιπλέον οι τύποι του πληθυντικού να διαθέτουν και την ανάλογη εικονικότητα. Άρα το σύστημα καταργεί αυτή την κλιτική τάξη, δηλ. δεν δημιουργεί νέες απλές λέξεις σε -ος. Το καλύτερο που μπορεί να κάνει η τάξη αυτή είναι να μειώσει τους τύπους από 4 σε 3: το κατορθώνει με την κλητική ορισμένων κύριων ονομάτων σε -ο (αντί σε -ε)³⁴ ή με τη μετακίνηση του ουσιαστικού στην ΚΤ των σε -ας, π.χ. *ο θύλακας/τους θύλακες* (αντί *ο θύλακος/τους θυλάκους*). Επίσης έτσι ερμηνεύουμε την κατάργηση του τύπου της αιτιατικής σε ορισμένα ιδιώματα, π.χ. *έχεις κολιού;* (Νικήτη Χαλκιδικής) (κοινή ΝΕ *έχεις κολιούς;*). Η κατάργηση είναι απόλυτα σύμφωνη με τις τάσεις του ΝΕ συστήματος. Βέβαια η κατάργηση αυτή δεν είναι άμεσα ορατή, γιατί α) πολλά αρσενικά σε -ος είναι συχνόχρηστα και συνεπώς σε σχέση με τη γνωστική επεξεργασία αφενός είναι βαθιά ριζωμένα και αφετέρου ανακαλούνται γρήγορα,³⁵ και β) κατασκευάζονται νέες λέξεις όχι απλές αλλά παράγωγες με τα επιθήματα λ.χ. -ίσκος, -ισμός, -μός π.χ. *ημετερ-ισμός, εκπασοκισ-μός*, ή σύνθετες με ήδη υπάρχοντα στοιχεία, π.χ. *καναπεδάνθρωπος, ρεμπετολόγος, εικονοφάγος, ποδοσφαιρογράφος*.

Με ποια μέσα επιτυγχάνεται ο λιτός τρόπος, ενώ επιζητείται η σαφής διάκριση των κατηγοριών; Η οικονομία επιτυγχάνεται με τρεις τρόπους:

Α) Αναγνωρισιμότητα του θέματος

Η σταθερότητα στη θέση του τόνου, η διατήρηση του θεματικού φωνήεντος μέσω της ανισοσυλλαβίας στον πληθυντικό,³⁶ η κατάργηση των ενθημάτων³⁷, των μεταπτωτικών βαθμίδων π.χ. *λέγω/λόγος*, όλα αυτά συμβάλλουν στην αναγνωρισιμότητα του θέματος και κατ' επέκταση του λεξιήματος.

Ήδη ο Φιλήντας (1927 : 39) σημειώνει ότι ο περιττοσυλλαβισμός στη ΝΕ προέκυψε από την τάση της ελληνικής να διατηρεί το ίδιο τερματικό θεματικό φωνήεν, δηλ. διατηρείται το θεματικό φωνήεν (ο χαρακτήρας) σε όλο το κλιτικό παράδειγμα, πράγμα που συμβάλλει στη σταθερότητα της μορφής του θέματος και συνεπώς στην αναγνωρισιμότητά του.

Απαιτείται η σταθερότητα της μορφής του θέματος (χωρίς ετεροίωση, χωρίς ενθήματα, χωρίς μετακίνηση του τόνου). Έτσι ερμηνεύουμε το ότι ισοσύλλαβα ουσιαστικά ανέπτυξαν και δεύτερο τρόπο κλίσης [-λόγιο] κατά το πρότυπο των ανισοσυλλάβων (βλ. παραπάνω): *γιαγιά* – *γιαγιές/γιαγιάδες*, *ναύτης* – *ναύτες/ναύτηδες*, *άρχοντας* – *άρχοντες/αρχοντάδες*, *λεβέντης* – *λεβέντες/λεβέντηδες*, *άλογο* – *άλογα/αλόγατα*.

Β) Σταθερότητα του τόνου

Η σταθερότητα του τόνου έχει ως αποτέλεσμα να διατηρείται ο τόνος στην ίδια συλλαβή με το λημματικό τύπο.

Ποιος είναι ο βασικός αλγόριθμος τονισμού για σύστημα λεξικού τονισμού όπως της ΝΕ; Η Ρεβυθιάδου (1999) έχει δώσει πειστικές απαντήσεις.

³³ Στην πραγματικότητα γίνεται ακόμη πιο περιορισμένη διάκριση, αφού διακρίνεται η ονομαστική/αιτιατική/κλητική από τη μια από τη γενική για τα θηλυκά και τα ουδέτερα από την άλλη. Η αιτιατική, που ανήκει στις πλάγιες πτώσεις, δε διακρίνεται πάντα από την ονομαστική. Διακρίνεται στα αρσενικά, όπου διαφοροποιούνται οι ορθές από τις πλάγιες πτώσεις με εξαίρεση την κλητική, που, αν και ορθή πτώση, έχει, εκτός από τα σε -ος, την ίδια μορφή με την αιτιατική ενικού.

³⁴ Στις Γραμματικές δεν υπάρχει συμφωνία στον τρόπο σχηματισμού της κλητικής των ουσ. σε -ος: Τα αρσενικά σε -ος με τόνο στην παραλήγουσα σχηματίζουν κλητική σε -ο, π.χ. *Αλέκο, Νίκο*, αλλά *Αλέξανδρε, Φίλιππε, Στέφανε*, όπως *γέρο* και τα σε -άκος, π.χ. *φιλαράκο* (Holton et al. 2007: 48). Ωστόσο ο Tonnet (2006: 82) παρατηρεί ότι η κλητική είναι ίδια με την αιτιατική στα [-λόγια] βαφτιστικά και στα παροξύτονα οικογενειακά ονόματα, π.χ. *Πάνο, Αλέκο, κύριε Βενιζέλο, Ξαρχάκο*, ενώ *Αλέξανδρε, κύριε Παπαδόπουλε*. Για τους Κλαίρη & Μπαμπινιώτη (1996: 51) τα περισσότερα αρσενικά σε -ος σχηματίζουν την κλητική σε -ε, π.χ. *Θόδωρε*, με εξαίρεση τα δυσύλλαβα, που τη σχηματίζουν σε -ο, π.χ. *Γιώργο*. Για τον Χατζησαββίδη (2009: 153) ο τύπος *Πάυλε* θεωρείται ότι ανήκει στο οικείο ύφος, ενώ στη νόρμα ανήκει ο τύπος *Πάυλο*.

³⁵ Στο γνωστικό επίπεδο η συχνότητα πληροφορεί την εσωτερικευμένη γραμματική των ομιλητών, στο βαθμό που η συχνότητα μιας μονάδας ευνοεί την απομνημόνευσή της, την εγκατάστασή της, αλλά επίσης και την ενδεχόμενη φωνολογική απομείωση, όταν η συχνότητα είναι ιδιαίτερα υψηλή (Legallois & Francois 2011 : 10).

³⁶ Στην ΑΕ το θεματικό φωνήεν μεταβάλλεται συχνά από πτώση σε πτώση.

³⁷ Λ.χ. Στην ΑΕ το ρηματικό θέμα *λαβ-* διακόπτεται από το ένθημα -μ- για το σχηματισμό του ενεστώτα (*λαμβάνω*).

Ο κανόνας για τη ΝΕ είναι ο τόνος να παραμένει σταθερός. Τα ουσιαστικά στα οποία κατεβαίνει ο τόνος είναι κληρονομημένα. Η σταθερότητα του τόνου συμβάλλει στην αναγνωρισιμότητα του θέματος. Ενδιαφέρον παρουσιάζει η παρατήρησή μας ότι δύο βασικά χαρακτηριστικά του ΝΕ κλιτικού συστήματος –ανισοσυλλαβία και σταθερότητα του τόνου– συνδέονται στενά: τα ανισοσύλλαβα διατηρούν σταθερό τον τόνο στη γενική πληθυντικού, π.χ. *μαϊμού/μαϊμούδων*. Ωστόσο από τα δύο χαρακτηριστικά πιο ισχυρό είναι η ανισοσυλλαβία, επειδή η θέση του τόνου περιορίζεται από το νόμο της τρισυλλαβίας: στην περίπτωση *άλογο/άλογα* – *αλόγατα* η ανισοσυλλαβία ισχύει, ενώ ο τόνος μετακινείται λόγω του περιορισμού της τρισυλλαβίας.

Ακόμη η διατήρηση του τόνου στην ίδια συλλαβή καθορίζει την επιλογή του θέματος κατά την κατασκευή των παραγώγων σε –*ικος* (βλ. παραπάνω). Βάση και παράγωγο τονίζονται στην ίδια συλλαβή: π.χ. *ψαρά-/ψαράδ-* → **ψάρ-ικος/ψαράδ-ικος* (επιλέχθηκε το Θ2β) αλλά *μανάβη/μανάβηδ-* → *μανάβ-ικος/*μαναβήδ-ικος* (επιλέχθηκε το Θ2α).

Γ) Ο περιορισμένος αριθμός των κλιτικών μορφημάτων με σαφή λειτουργία στο πρωτοτυπικό σύστημα: –ς δείκτης αρσενικότητας, –ων γενική πληθυντικού, –ες ονομαστική/αιτιατική/κλητική πληθυντικού αρσενικών και θηλυκών και –α ονομαστική/αιτιατική/κλητική πληθυντικού ουδετέρων.

5. Εφαρμογή

Η έρευνα αυτή πέρα από το θεωρητικό ενδιαφέρον της μπορεί να έχει ποικίλες εφαρμογές τόσο στο χώρο της υπολογιστικής γλωσσολογίας, γιατί παρέχει περιγραφή που χαρακτηρίζεται από πληρότητα και οικονομία, όσο και στο χώρο της διδακτικής της ΝΕ ιδίως ως δεύτερης/ξένης γλώσσας, επειδή δεν παρουσιάζονται όλες οι ΚΤ ισοπεδωτικά ισοδύναμες, αλλά λαμβάνονται υπόψη κριτήρια όπως το πρωτοτυπικό μορφολογικό σύστημα κλίσης, η συχνότητα και η διαθεσιμότητα των δομών.

Ένα κλιτικό σύστημα όπως της ΝΕ που έχει 2 βασικά χαρακτηριστικά, τη λιτότητα και τη σαφή διάκριση των κατηγοριών, πρέπει να είναι απλό στη διδασκαλία του, γιατί αφενός λόγω λιτότητας είναι περιορισμένος ο αριθμός των κλιτικών μορφημάτων και του τρόπου κατασκευής των θεμάτων, και αφετέρου λόγω της επιζητούμενης σαφήνειας των κατηγοριών υπεισέρχονται οι σημασιολογικές διακρίσεις, π.χ. ενικός-πληθυντικός, και συνεπώς είναι πιο εύκολη η εκμάθησή του.

Τόσο στις Γραμματικές όσο και στα εγχειρίδια διδασκαλίας της ΝΕ ως μητρικής και ως δεύτερης/ξένης δεν λαμβάνεται ουσιαστική πρόνοια για ανάδειξη της απλότητας του κλιτικού συστήματος της ΝΕ. Λ.χ. η κλιτική τάξη των αρσενικών σε –*ος* διδάσκεται ήδη από τα πρώτα μαθήματα, ενώ δεν αποτελεί πρωτοτυπική τάξη του ΝΕ κλιτικού συστήματος ούτε πρόκειται για διαθέσιμη κλιτική τάξη. Αρκεί η αναμφισβήτητη συχνότητα χρήσης ορισμένων λεξημάτων της ΚΤ3 (αρσενικά ουσιαστικά σε –*ος*) για να δικαιολογηθεί η ισχυρή θέση που κατέχει η κλίση αυτής της ΚΤ στις γραμματικές περιγραφές και στα εγχειρίδια εκμάθησης της ΝΕ (Αναστασιάδη-Συμεωνίδη 2003);

6. Επίλογος

Η περιγραφή αυτή στηρίζεται σε 81.200 μονολεκτικά ουσιαστικά της ΝΕ, που συνιστά τον πιο ενημερωμένο κατάλογο κοινών ουσιαστικών της ΝΕ.

Η ανάλυση αυτή είναι καινοτόμος ως προς τα εξής σημεία:

1. Πρόβλεψη του δεύτερου θέματος από το πρώτο, π.χ. από το Θ1 *πεισματορη-* → το Θ2 *πεισματορηδ-*
2. Ενοποιημένη περιγραφή των ομαλών και ανώμαλων ουσιαστικών.
3. Περιγραφή που λαμβάνει υπόψη τη διαθεσιμότητα των ΚΤ: οι ΚΤ1, ΚΤ2, ΚΤ4 είναι διαθέσιμες, σε αντίθεση με την ΚΤ6 που δεν είναι διαθέσιμη και την ΚΤ 3 όσον αφορά το σχηματισμό απλών (όχι σύνθετων) λεξικών μονάδων.
4. Ενοποιημένη περιγραφή των μορφολογικών διαδικασιών (κλίσης-παραγωγής-σύνθεσης) με την υιοθέτηση της έννοιας του θεματικού χώρου.
5. Ενσωμάτωση του χαρακτηριστικού [+/-λόγιο] στην κλίση των ουσιαστικών.

SOME INSIGHTS INTO EVIDENTIALITY AND EVIDENTIAL MARKERS IN FRENCH¹

Jean-Claude Anscombre

LDI-CNRS (Paris XIII)

janscombre@ldi.univ-paris13.fr

ABSTRACT

A common approach to evidentiality distinguishes three main subcategories of phenomena: evidentiality by inference, by hearsay and by perception. If elementary cases look quite obvious, the problems arise as soon as we intent to give more accurate definitions. This work is an attempt to answer the following questions, on the bases of examples mainly taken from French.: a) What are the grounds that allow an inference by the speaker? Is it really a logical process that is at work, or rather some commonplace knowledge that thus would approximate inferential reasoning to some kind of hearsay mechanism; b) How does the speaker/utterer get involved in the hearsay process? What are the different positions he can occupy with regard to the source of a hearsay? c) Are there linguistic characteristics which reflects the intervening of a perception?

Keywords: Evidentiality, evidential markers, hearsay, inference, perception, semantics.

0. Introduction

Despite the fact that languages obviously consider that human awareness of truth is fairly relative, it is not until recently that studies have been devoted to the different devices used by languages to express the origin of the information carried by a sentence and/or the various attitudes of a speaker towards this knowledge. If languages are used to provide a wide repertoire of devices for expressing these characteristics, their nature usually varies from one language to another one: verbal, nominal, adverbial, etc. The study of such devices has been termed *evidentiality*², each device being an *evidential marker*, and the way in which different languages provide evidential marking is a general question still to be explored. Since it sometimes deals with the speaker's attitude towards the situation s/he refers to in her/his utterance, as we will see later on, evidentiality is obviously part of modality, more precisely **epistemic modality**³.

A commonly accepted claim - based on the wide amount of data investigated until today - is that languages tend to differentiate three general kinds of evidentiality, which can be classified into **direct evidence** and **indirect evidence**. **Direct evidence**, also labeled **attested** or **perceptual evidence**, involves any knowledge acquired through auditory, gustative, olfactory, tactile and visual senses, i.e. by a sensory mode. The indirect type of evidence is the well-known **reported evidence**, better known as **hearsay evidence**, and the **inferred evidence**. From now on, I will, in short, speak of the **perception** type, of the **hearsay** type, and of the **inference** type. Needless to say, these three types can be divided into subsubclasses, a point which will not be considered here. The three types can be exemplified in:

- (1) John must be in his office, his car is in the parking (inference type).
- (2) I was told that John is in his office (hearsay type).

¹ This work is part of the Research Project FFI2009-08714 « Dictionnaire d'opérateurs sémantico-pragmatiques en français contemporain », supported by the *Ministerio de Ciencia e Innovación Español*.

² The notion of *evidentiality* as a linguistic information is commonly attributed to Franz Boas in his *Handbook of American Indian Languages* (1911). The term *evidential* was first used by Roman Jakobson in 1957 as a verbal category to be distinguished from grammatical mood.

³ Some scholars like Chafe: 1986, include *belief* among evidentials, as part of the epistemic system, while others like Bybee: 1985 or Willett: 1988, are more reluctant. The crux of the problem lies in whether evidentiality only deals with the marking of the source of the knowledge, or also includes the speaker's attitude towards this knowledge.

(3) I can hear John speaking with Mary in his office (perception type).
Such cases may look quite obvious as for their interpretation, but the problems arise as soon as we intend to give to each of these categories a more accurate definition. This work is an attempt to answer the following questions, among others, in the case of explicit evidential markers:

a) What are the grounds that allow an inference by the speaker, as in (1))? Is it really a logical process that is at work, or rather some commonplace knowledge that thus would approximate inferential reasoning to some kind of hearsay mechanism.

b) How does the speaker/utterer get involved in the hearsay process? What are the different positions he can occupy with regard to the source of a hearsay?

c) In the case of French, on which linguistic grounds can we determine the nature of the evidence, especially in the case of the perception type?

1. The hearsay type

We will start with the hearsay type, which is – or at least seems to be – the more obvious or visible type in Western languages. The base of hearsay is language itself, since we know an important part of the things we know because we have been told about them by some other people. Languages such as English, French or Spanish have a wide variety of devices to qualify a given knowledge as having been acquired through language communication. Some markers refer to a specific source as *à mon avis/in my opinion/a mi parecer*; others refer to some indeterminate linguistic community: *on dit que, comme on dit, they say, as they say, people say*, etc.; *dicen, como dicen, cuentan en la prensa*, etc. Here are a few real examples:

- (4) "...**Les sondages, qui affirment** que Hilary gagnerait haut la main contre Mc Cain, n'ont pas convaincu le gagnant des primaires démocrates..." (*L'Express*, 28 juillet 2008, p. 32).
[The polls, that claim...].
- (5) "...Il est imprudent de mettre, **comme on dit**, tous ses oeufs dans le même panier..." (Gide, *Robert ou l'intérêt général*, III,) [As the saying goes...].
- (6) "...**Dicen que** antes de morir – comentó el croata – se debe plantar un árbol, escribir un libro y tener un hijo..." (A. Pérez-Reverte, *El pintor de batallas*, Alfaguara, Madrid, 2006, p. 215) [They say that...].
- (7) "...Del que te manda, hay que cuidarse siempre. – *Del amo y del mulo, cuanto más lejos más seguro, como dicen en mi pueblo* – añadió Robles..." (L. Silva, *La reina sin espejo*, p. 169) [...as they say in my village...].
- (8) "...It did no good to think back. The mill cannot grind with the water that is past, **as the old people in the mountain used to say**..." (G. Richards, *Red Kill*, 1980, XIV).
- (9) "...**They do say** that a trouble shared is a trouble halved..." (F.Cradock, *Thunder over Castle Rising*, 1980, i).

From now on, I will refer to an indeterminate source of a hearsay as a G-speaker, and will concentrate on the study of such G-speakers in Modern French. I will mainly examine two points: a) How can we claim we are dealing with a G-speaker; b) What is the relation between the G-speaker (the source) and the speaker of the utterance.

We will examine the following French evidential markers: *on dit que* ('they say that'), *comme on dit* ('as they say'), and *dit-on* ('...', it is said, .../somepeople say'). They show the following characteristics:

a) They use the French verb *dire* 'to say', as a verb of saying, which can be seen by the possibility of substitution of *dire* by other verbs of saying:

- (10) *On (dit + affirme (state) + prétend (claim) + raconte (tell) + ...) que...*
- (11) *Comme on (dit + prétend + l'affirme + le raconte + ...), ...*
- (12) *p, (dit-on + prétend-on + affirme-t-on + raconte-t-on + ...).*

b) French *on* can refer to a community of people, but it is not the only possibility, so that we must find out the linguistic properties supporting the claim that a G-speaker is at work in such expressions. Among other properties, the *on* referring to a G-speaker:

(i) Can be combined with adverbials such as *généralement* ('generally'), *communément* ('commonly'), *couramment* ('currently'), *habituellement* ('usually'), etc. :

- (13) *Comme on dit communément*, tout est bien qui finit bien (= 'As they commonly say, all is well that ends well').
- (14) Une crise se prépare, dit-on **généralement** (= 'A crisis is in the wind, it is generally said').

- (15) On dit **généralement** que les fameux OVNIS ne sont que de banals phénomènes atmosphériques (= 'They generally say that the well-known UFOS are just mere atmospheric phenomena').
- (ii) Can be combined with aspectual adverbials such as *toujours* ('always'), *souvent* ('often'), *parfois* ('sometimes'), which are compatibles with an interpretation in terms of indefinite plurality :
- (16) On dit **toujours** qu'il vaut mieux se préparer au pire ('They use to say that ~~the worst~~ is yet to come').
- (17) Les fameux OVNIS ne sont que de banals phénomènes atmosphériques, dit-on **parfois** ('It is sometimes said').
- (18) Comme on dit **souvent**, un bon tiens vaut mieux que deux tu l'auras ('As they often say, better a bird in the hand than two in the bush').
- (iii) Can be combined with a **collective noun**⁴, that is a nominal that refers to a set of several unspecified entities of the same category, and cannot be given a definition in extension. Very common examples of collective nouns would be items like *les milieux autorisés* 'the responsible quarters', and *les milieux bien informés* 'the well informed people', *la presse* 'the newspapers'. We should also mention expressions like *chez les scientifiques* 'among the scientists'. Below some examples:
- (19) On dit **dans les milieux autorisés** qu'une crise se prépare ('in the responsible quarters').
- (20) Comme on dit **chez les scientifiques**, les fameux OVNIS ne sont que de banals phénomènes atmosphériques .
- (21) Le premier ministre serait sur le point de démissionner, dit-on **dans l'entourage du président** ('among the familiars of the president')

We will now aim to determine how does the speaker locates him/herself with respect to the G-speaker, being a G-speaker in a linguistic community, that is a set of real or virtual speakers. The results of our investigation show the following configurations:

a) The speaker S of *on dit que* can be part of the G-speaker involved, but not necessarily. In this respect, *on dit que* is opposed to *on sait que*⁵, which necessarily includes the speaker S, as exemplified in:

- (22) (**On dit + on sait**) qu'il y a un changement climatique en cours, et c'est indiscutable (= 'there is no question about it').
- (23) (**On dit + *on sait**) qu'il y a un changement climatique en cours, mais je suis loin d'être de cet avis (= 'I am far from being of the same opinion').

b) The speaker S of *comme on dit, p* belongs to the community attached to the G-speaker involved, as can be seen in:

- (24) **On dit que** ce n'est pas la mer à boire, (**et je suis bien de cet avis + mais je ne suis pas de cet avis**).
- (25) **Comme on dit**, ce n'est pas la mer à boire, (**et je suis bien de cet avis + *mais je ne suis pas de cet avis**).

c) The speaker of *dit-on* does not belong to the community attached to the G-speaker involved, as can be seen in the following contrasts:

- (26) **On dit** qu'il y a un réchauffement climatique, (et selon moi, on a raison + mais selon moi, on a tort) (= 'In my view, (they are right + they are wrong)').
- (27) Il y a un réchauffement climatique, **dit-on**, (*et selon moi, on a raison + mais selon moi, on a tort).

Moreover, *dit-on* cannot combine with an utterance that asserts some truth shared by the speaker. Hence the following contrasts:

- (28) **On dit** que je sais que Max est à Paris ('They say that I know that Max is in Paris').
- (29) ??Je sais que Max est à Paris, **dit-on**⁶ ('I know that Max is in Paris, some people say').
- (30) Je **saurais** que Max est à Paris, **dit-on** ('I am supposed to know that Max is in Paris, some people say').

Since its pragmasemantic value is not predictable on the base of the usual value of the subject-verb inversion in parentheticals, the evidential marker *dit-on* then appears to be a grammaticalized or even

⁴ See Lecolle : 1998.

⁵ *On dit* means 'they say', but *on sait* does not mean 'they know', but rather 'we know, it is a well known fact'.

⁶ Is possible only if *je sais* is some kind of reported speech, in which case *je* does not refer to the speaker as such.

pragmaticalized sequence. It shows a clear contrast with similar markers like *dis-je*, *dis-tu* and *dit-il* which are usually intended to recall a former utterance⁷.

A quite intriguing case is the combination of *dit-on* with gnomic utterances, especially proverbs or sayings, as in:

- (31) Les apparences sont trompeuses, dit-on ('Appearances can be deceiving, it is said').
- (32) L'avenir appartient à celui qui se lève tôt, dit-on ('The early bird catches the worm, it is said').

A fact that seems to contradict our characterization of *dit-on*, since sayings are normally shared by the whole community of speakers. In fact, utterances like (31) and (32) are meant – at least in French – to advise somebody. They can be interpreted as meaning 'I don't want to interfere, but some people would apply the following principle...'.⁸

A first conclusion is that in addition to the origin of the information, evidential markers currently tell us something about the position of the speaker as regards this information and its origin. In this aspect, evidential markers show similarities with modalities seen as the speaker's attitude toward what is said.

2. The inference type

As with the hearsay type, the inference type is part of indirect evidence. A first point is the definition itself of the word **inference**. We will from now on call **inference** any sequence of operations starting from a set of premises and ending with a set of conclusions. According to the nature of the mechanism ensuring the inference, three types have been usually distinguished⁸: a) the **deductive** one; b) the **inductive** one; c) the **abductive** one. The first type comes under logic, the last two under reasoning. The most obvious case of inference is of course the logical one: from a given state of affairs, one can deduce some specific consequences in virtue of a logical law. As an example, let's examine Pierce's example:

- (33) 1. All the beans from this bag are white
- 2. These beans are from this bag.
- 3. (Then) These beans are white.

Being the mechanism the well-known *modus ponens*: if $p \rightarrow q$ and if p , then q . The inductive reasoning draws generalizations from specific cases, as in Pierce's example:

- (34) 1. These beans are from this bag.
- 2. These beans are white.
- 3. (Then) All the beans from this bag are white.

As for the abductive reasoning, it is based on the following schema:

- (35) 1. All the beans from this bag are white.
- 2. These beans are white.
- 3. (Then) These beans are from this bag.

That is: if $p \rightarrow q$ and q , then p ⁹.

In fact, deductive reasoning should be divided into two subcategories, namely **logical deduction** as in (33), and **plausible deduction**, which is based on arguments, as in:

- (36) 1. When somebody works hard, he is (usually) tired.
- 2. I have been working hard lately.
- 3. (Hence) I am (likely to be) tired.

The point is now to find out on which grounds the inference is made. To clarify the type of problems bound to the notion of evidential inference, I will take an example from Guentcheva: 1986, namely:

- (37) John [must have] left, his luggage is no longer in his room.

The central factual claim is obviously *John's luggage is no longer in his room*, being *John left* the plausible conclusion drawn by inference from the factual claim. The inference itself is a kind of circumstantial inference based upon a rule like [When the luggage of a person is no longer in his room, the person has left the room], which can be considered as an abduction from the gnomic R = [When a

⁷ For analogous facts in English, compare the (somewhat unusual) parenthetical *say I, said he*, etc. and the colloquial expression *Says you!*

⁸ Pierce: 1965.

⁹ Guentcheva: 1994, gives several examples of abductive inference in everyday language, such as *We have been broken into!*

person leaves his room, he takes his own luggage away]. (37) is then to be classified as a plausible deduction, being the problem the linguistic status of R. There are two possibilities: the first one consists in seeing R as an abstract pattern, the second considers R as some sort of virtual utterance belonging to a common knowledge. In this second case, R is not an explicit but rather an underlying causal principle, but can very often be made explicit, as in:

- (38) John [must have] left, his luggage is no longer in his room, and usually, [When a person leaves his room, he takes his own luggage away].

Let's now see a case of induction, as in:

- (39) If you are going to Spain, mind Spanish flies, one bit me last year.

Once again, the inference rests upon a rule, namely [Spanish flies bite], which again is not an explicit but an underlying principle and is called up by the factual claim *one bit me last year*. And once again the problem arises of the status of the rule. Last but not least, there is a very well-known category of such gnomic rules that are clearly related to a virtual speaker, namely the proverbs and other sayings. We tend to use sayings as inferential mechanisms, as exemplified in:

- (40) "...Show him the stuff. Let him make his own mind up. – Okay. May be you're right at that. Seeing is believing, I guess..." (A. Price, *Our man in Camelot*, 1975).

The speaker of (40) is the speaker of the saying, but in no way the origin of it, which is something like some collective wisdom that is depicted as a virtual voice – *as they say, it is said*, etc.

A consequence then of the second possibility is that it approximates the inference type to some kind of hearsay type, since the inferential mechanism is then considered to be due to a virtual speaker that can be made explicit for instance in cases like sayings. A problem of choosing the first possibility is that it makes it difficult to represent the way the inference works in reality. In the case of (38) for instance, the inference should go this way:

- (41) 1. [When a person leaves his room, he takes his own luggage away].
2. John's luggage is no longer in his room.
3. (Then) John left his room (by abduction).

2. is a factual claim and then an utterance and 3. the utterance that is drawn by inference from 1. and 2. But this is possible only and only if 1. is also an utterance. In the first option, it is not so and 1. is an abstract principle, that is a meta-linguistic proposition. (40) then will work only if 1 is said in a way or another to be equivalent to a real utterance.

To conclude the above, we can see the boundaries between the hearsay type and the inference type are not clearly established. As we have seen before, sayings and proverbs belong to the hearsay type but are used in inferential processes. On the other hand, inferential processes usually rest upon common grounds that might be interpreted as having a hearsay nature.

3. The perception type

As said before, the perception type is part of direct evidence, and involves any sensory mode, auditory, gustative, olfactory, tactile and visual senses as well. As quoted by Anderson: 1986. We usually tend to take our perceptions for granted, and see any perception verb as giving rise to an evidential. Unfortunately, things are not that simple, and in most cases the use of a perception verb is ambiguous between a mere predication and an evidential, as exemplified in:

- (42) It looks like gold ('it has the same aspect as gold' + 'it is gold according to my visual perception').

On the other hand, the perception type is primarily a perception type, and its sensory nature is not due to some pragmatic inference. In the following example:

- (43) The door is open.

I know that the door is open because I hear (43) or read it, but it means in no way that we have acquired such knowledge through a perception: (43) *implies* a perception, but does not *mean it*. Perception verbs have not given rise to many studies: from a syntactical point of view, see Willems (1981, 2000) for French; and from a semantic point of view, the *Perceptual Reports* have been analyzed as sentences within the intensional framework of *Situation Semantics* (Barwise: 1981, Perry and Barwise: 1981), and as indefinite descriptions of an event within the extensional framework of (Higginbotham: 1984). As in many other languages, French has perception verbs, about thirty, the more frequent being *apercevoir* (perceive), *contempler* (contemplate), *écouter* (listen), *entendre* (hear),

goûter (taste), *observer* (observe), *regarder* (watch), *sentir* (smell), *voir* (see), etc. The problem in both French and in English is that a perceptual report (*naked infinitive*) like:

- (44) Jean a vu Marie pleurer ('John saw Mary weep').

Is totally ambiguous between a mere predication 'What John saw was Mary weep', where *John saw* is the main predication, and an evidential 'Mary wept, John saw it', where this time *Mary wept* is the main predication. The distinction between true evidential and non-evidential interpretation of a perceptual report is not easy to make, and as far as I know, very few studies have been devoted to find out specific properties related to the evidential interpretation. I will now turn precisely to an indirect way of showing up the presence of a perceptual evidence.

In French, the verb *trouver* 'to find', is very commonly used to express a judgment or an opinion through the construction *je trouve que* 'I find that':

- (45) Je trouve que cette pièce de théâtre est excellente ('I find that this play is excellent').

Such a verb also exists in English, Portuguese and Catalan, but in Spanish for instance, its use is restricted to noun phrases: *La obra de teatro, la encuentro excelente*? *Encuentro excelente la obra de teatro* /**Encuentro que la obra de teatro es excelente*. The verb *trouver* has two interesting characteristics:

a) First, it shares with perception verbs like *voir* 'see' the possibility of a double construction, namely noun phrase and finite clause:

- (46) Je vois Marie impatiente/Je vois que Marie est impatiente ('I see Mary impatient/I see that Mary is impatient')

- (47) Je trouve Marie impatiente/Je trouve que Marie est impatiente ('I find Mary impatient/I find that Mary is impatient').

b) An utterance of *Je trouve que SN + V* is possible only if the speaker has had a **direct experience** of SN¹⁰. Hence the following examples:

- (48) Je n'ai pas vu cette pièce, mais (je crois + *je trouve) qu'elle est excellente.
(I have not seen this play, but (I think + I find) that it is excellent')
- (49) Je n'ai pas goûté ce vin, mais (je pense + *je trouve) qu'il est excellent.
(I have not tasted that wine, but (I think + I find) that it is excellent')
- (50) Je n'ai pas senti ce parfum, mais (j'ai l'impression + *je trouve) qu'il est très frais.
(I have not smelled that perfume, but (I think + I find) that it is very fresh')
- (51) Je n'ai pas encore écouté ce disque, mais (je suis sûr + *je trouve) que l'interprétation est remarquable.
(I have not played that record, but (I am certain + I find) that the interpretation is remarkable')
- (52) Sans avoir touché le tissu, (je parie + *je trouve) qu'il est très doux.
Without touching the fabric, (I bet + I find) that it is smooth

As opposed to:

- (53) J'ai vu cette pièce, et je trouve qu'elle est excellente.
(I saw this play, and I find it is excellent')
- (54) J'ai goûté ce vin, et je trouve qu'il est excellent.
(I tasted this wine, and I find that it is excellent')
- (55) J'ai senti ce parfum, et je trouve qu'il est très frais.
(I smelled this perfume, and I find that it is very fresh')
- (56) J'ai écouté ce disque, et je trouve que l'interprétation est remarquable.
(I played this record, and I find that the interpretation is remarkable')
- (57) J'ai touché le tissu, et je trouve qu'il est très doux.
(I touched the fabric, and I find that it is very smooth').

Hence, the French verb *trouver* provides us a criterion to determine a subclass of perceptual evidentials. Not the whole class, since *trouver* implies that a judgment be possible.

What has been said above has an important consequence on the notion of direct evidence. Consider the following examples (Anscombe: 2010b):

- (58) Je trouve que la mort de César a été horrible.
(I found Caesar's death horrible').
- (59) Je trouve horrible de mourir à vingt ans.
(I find it horrible to die being twenty years old').

¹⁰ Ducrot: 1975.

It is fairly obvious that the speaker cannot have a 'direct experience' of Caesar's death, neither can he have a direct experience of 'dying being twenty years old'. In fact, some common knowledge is considered as taken for granted, and hence is considered as direct experiences. It can be historical knowledge as in (58), or else common places as in (59), which relies upon something like 'One dies when one is old'. Direct evidence appears then to refer to things that are considered as unquestionable facts, based on perceptual facts and on historical facts or commonplaces as well. Further investigations should then examine the linguistic relationship between *hear-say* phenomena and perceptual reports.

THE GREEK FUTURE: EPISTEMIC MODALITY AND MODAL CONCORD

Anastasia Giannakidou

University of Chicago

giannaki@uchicago.edu

ABSTRACT

*In this paper, I propose an analysis of the Greek so-called ‘future’ particle *tha* (θα) as an epistemic necessity modal operator with present perspective. This analysis renders *tha* similar to the English modal *must*—and as in English, I will argue that we find evidential uses (further studied in Giannakidou and Mari to appear, and shown to hold in both Greek and Italian). The main evidence for the modality of *tha* will be drawn from co-occurrence with modal adverbs which constitutes, I will argue, modal concord in the sense of Huitink (2012). My analysis is similar to Tsangalidis (1999) who argues that the particle *tha* is not a prototypical future tense marker—but differs from Tsangalidis who claims that *tha* is not a modal operator either. The major implications of what I propose here is that the category ‘future’ is modal, at least in Greek, and that the ‘future’ reading is simply forward shifting of the time of the event due to the presence of an adverbial.*

1. The future: tense or modality?

The question of whether the category ‘future tense’ in natural languages is a tense or modality has been central in linguistic semantics, and both answers have been explored (for modal accounts, see Prior, 1967; Bertinetto, 1979; Copley, 2002; Squartini, 2004; Mari, 2009, Klecha 2011; for a defense of the temporal analysis see Kissine 2008). Certainly, the English future word ‘will’ has been known to admit purely modal readings, and is typically characterized in the grammars as a modal verb. We also read, for instance in Palmer (1987), that “it is tempting to refer to the meaning of *will* as probability, alongside possibility and necessity for *may* and *must*. But the word ‘probable’ does not provide a good paraphrase. A better paraphrase is again in terms of conclusion: ‘A reasonable conclusion is that.. (Palmer 1987: 136)’.”

- (1) The French’ll be on holiday this week.
- (2) No doubt, you’ll remember John.

The sentences above with *will* are conjectural rather than temporal, and *will* seems to convey a sort of ‘inferential’, epistemic modality: *given what I know, it is quite likely* or *it is quite plausible*, or in cases of stronger certainty, *it must be the case* that that the French are on holiday this week. The modality is stronger than mere possibility, and ranges from strong probability to weak and classical necessity (Kratzer 1981, 1991). However, *must* and *will* are not equivalent:

- (3) John will be in his office.
- (4) John must be in his office (Palmer 1987: 136).

Must conveys stronger certainty than *will* in the pair above, and it also seems to have an evidential component (see von Stechow and Gillies 2010 and references therein): *all the worlds compatible with the best indirect evidence I have*, are worlds where John is in his office. *Must*, at the same time, unlike *will*, does not necessarily make reference to a time after the utterance time:

- (5) Utterance time, 9 pm: John must have left at 6 pm; #by 10 pm).
- (6) Utterance time, 9 pm: John will have left (#at 6 pm; by 10 pm).

In this paper, I will propose that the Greek future particle *tha* (θα) is, contrary to the traditional grammar label, not a future tense but a modality operator, pretty much like *will* and *must*. The epistemic, non-future, uses of *θα* have been known in the literature since Tzartanos' grammar (1953); they have also been noted in the grammar of Holton et al. (1997), and were studied in more detail in Tsangalidis's seminal work on *tha*. They have also acknowledged in more recent literature e.g. Chiou (2012). I will further show here that the 'future' reading itself is not devoid of epistemic modality either, there are therefore no purely temporal uses of *tha*. Tsangalidis himself reaches the conclusion that *tha* is neither a modal nor a temporal operator, but rather a hybrid, mixed category. The analysis I will propose in this paper treats *tha* as a modal (epistemic) operator, with present—not future—perspective (a position that I adopt from my earlier work (Giannakidou 2009)). In ongoing work, Giannakidou and Mari study the evidential component underlying *tha*, but given space limitations, I will not expand on this here.

The main argument for the modality of *tha* comes from its non-future readings with present and past, and from its interaction with modal adverbials. In the examination of this interaction, we discover that Greek exhibits rich patterns of modal concord, not only with *tha* but also with the other necessity modal *prepi*. I adopt Huitink's 2012 analysis of modal concord as a suitable framework for the analysis of Greek, but we also note a flexibility with both necessity modals in Greek that may be used as an argument for probability based theories of modality such as e.g. Lassiter (2011).

The modal analysis of *tha* has a variety of implications which set up a lively agenda for future research. First, it allows us to move beyond the choice *particle or verb?*, dictated by typological studies (Tsangalidis 1999) and which collapses essentially the semantic category 'modal operator' with the syntactic status of 'modal verb'. Modality is a semantic category that can have various syntactic realizations (Kratzer 1981, 1991, Portner 2009)— verbs, adverbs, morphemes such as *-able*— and as I suggest here also particles. It is misleading to reject the modal analysis of *tha* just because it is not, syntactically, a verb (see a similar point in Roussou and Tsangalidis 2010). Second, the modal analysis of *tha* establishes a correlation between epistemic modality and temporal interpretation, a route that has not been previously taken but which is very promising in allowing a better understanding of the category 'future'.

The paper unfolds as follows. In the next section, I describe the epistemic reading of *tha* in detail, along with the future use. Instrumental to this discussion is the co-occurrence of *tha* with modal adverbs, showing that the modal readings have a gradient force that is stronger than mere possibility, and closer to high probability and necessity. In section 3, I will outline the temporal polarity analysis of Giannakidou 2009 which I will use as the basis for the derivation of the future meaning; in section 4, I further develop the epistemic modal analysis of *tha* and offer a preliminary analysis of the modal concord patterns observed.

2. *Θα*: future, epistemic readings, and co-occurrence with modal adverbs

The Greek verb is obligatorily inflected for tense and aspect, and the particle *tha* is used with all four tense and aspect combinations: perfective non-past (PNP), perfective past (PP), imperfective non-past (INP) and imperfective past (IP). I illustrate the basic temporal/aspectual distinctions below (cf. Mackridge 1985, Holton et al. 1997):

- | | |
|---|--|
| <p>(7) a. graf- -o (INP)
 write.imperf -1sg.nonpast
 'I am writing (right now).'
 'I write (generally).'</p> | <p>b. grap- s- -o (PNP)
 write- perf.1sg.nonpast
 [no English equivalent; * on its own]</p> |
| <p>(8) a. e- graf- -a (IP)
 past- write.imperf. 1sg.past
 'I used to write.'
 'I was writing.'</p> | <p>b. e- grap- s- a (PP)
 past- write- perf.1sg.past
 'I wrote.'</p> |

The basic temporal opposition is between a morphological past, which is usually marked by the prefix *e-* attaching to the verbal stem and specific inflection; and a nonpast which is signaled by the absence of the prefix *e-* (hence the label *nonpast*), and which has its own inflection. The form in (7b)— the PNP— is a dependent form: it is not possible on its own, but only in combination with nonveridical particles (i.e. particles that create a nonveridical domain; Giannakidou 1998, 1999, 2009) such as the subjunctive *na*, *tha*, the optative *as*, *prin* 'before', *an* 'if':

- (9) a. **As** fiji o Janis.
 as leave.PNP.3sg the John
 ‘Let John go.’ (request or permission)
- b. **Na** fiji o Janis.
 na leave.PNP.3sg the John
 ‘Let John go.’ (request or permission)
- c. **Tha** fiji o Janis.
 tha leave.PNP.3sg the John
 ‘John will leave.’ (future)
- d. {**An/Prin**} fiji o Γιάννης....
 If/before leave.PNP.3sg the John
 ‘If/before John goes away....’

As we see in these examples, the combination nonveridical particle plus PNP creates future orientation: the intended event is to be located at an interval starting at the utterance time and stretching through the time afterward. So, future orientation is *not* an exclusive property of *tha*, but typical of the whole class of nonveridical particles and connectives in combination with this particular verbal form, the PNP. We also see that some of the particles function as higher modal or illocutionary force operators (e.g. the optative or the subjunctive), or they directly correspond to C positions as is the case with the connectives.

I will give examples of *tha* with each combination next, but I wanted first to frame the discussion by saying that in *all* combinations, even with the PNP, *θα* is interpreted epistemically. In addition, with PNP, we have the future reading, which is more due to properties of the PNP (Giannakidou 2009). My account differs from Tsangalidis (1999) who claims non-ambiguity and distinguishes between *tha* with PP which gives ‘pure’ epistemic past readings, and *tha* with the PNP which gives ‘pure’ non-epistemic future readings. (Tsangalidis allows the other combinations to be open to both temporal and modal readings). My claim is that there is no ‘pure’ future reading, and that the epistemic reading is always available with *tha* (see also Chiou 2012 for a similar intuition that the epistemic reading is generally available in all cases). It is important to note that Giannakidou and Mari (to appear) reach a similar conclusion for the Italian future suffix too.

Let us now consider in some detail the epistemic meaning of *tha*.

2.1 The epistemic reading of *θα*: co-occurrence with adverbs and the necessity modal

The epistemic reading arises as a ‘pure’ reading—in the sense of lacking future—in combinations of *tha* with imperfective non-past (INP) and perfective past (PP). I describe first the combination of *tha* with nonpast; the reading with the PP is exactly the same, only about a past event.

Consider the sentences below. In the glosses below I will refer to *tha* as FUT:

- (10) a. I Ariadne tha kimate tora.
 the Ariadne FUT sleep.INP.3sg now
 Ariadne must be sleeping now.
- b. I Ariadne tha ine giatros.
 the Ariadne FUT be.3sg doctor
 Ariadne must be a doctor.
- c. I Ariadne tha pezi tora.
 the Ariadne FUT play.INP.3sg now
 Ariadne must be playing now.

I use both stative and non-stative predicates, and as we see, in all cases, the most plausible paraphrase is the one indicated in the translations where I use the verb *must*. The reading is epistemic, inferential: I am considering information I have, and draw an inference based on that information. For example, with regard to (a), I know that Ariadne has the habit of taking a nap at 2pm, I also know that she always sticks to

schedule, and I also know that today has been a regular day. So at 2 pm, I utter the sentence expressing my relative certainty that Ariadne is, *for all I know*, asleep. Likewise, I know also that usually by 6 pm Ariadne is down at the yard playing with her friends. At any time after 6 pm then, I can utter (c) with the same degree of certainty. Finally, (b) expresses an inference that is more based on knowledge plus behavioral evidence: I have witnessed Ariadne expressing opinion on medical matters, she cites medical papers all the time, and similar things, hence I am entitled to conclude (b).

We must note that the certainty about the truth of the proposition is relatively strong, as we will witness below with the use of adverbials. But before we discuss that, it is important to mention that if I have direct evidence of the even happening, I cannot use *tha*. Just like in English, e.g., if I am watching the rain falling, it is quite weak to say “It must be raining”:

- (11) Context: I am watching the rain through the window. I say:
#*Tha vrex!* “It must be raining”.

This seems to suggest a sensitivity to the nature of evidence: if I have direct evidence to the truth of the sentence, *tha* is unacceptable. This sensitivity suggests that the statement with *tha* is weaker than the non-modalized assertion ‘It is raining’ or ‘Ariadne is a doctor’—weaker in the sense of nonveridical (Giannakidou 1998, 1999: not entailing the truth of the sentence in the context). Statements with indirect evidentials are similarly weak (nonveridical), and do not entail the truth of the sentence in the context—see for instance Fallor 2002, Smirnova 2011, and Murray 2012. If direct evidence supports the stronger statement, I am not being a co-operative speaker by choosing a weaker statement.

So, *tha* does convey a strong sense of certainty, it is still however non-veridical and conveys a non-homogeneous epistemic space that allows for the possibility that *not p*, like all modals (Giannakidou 1998, 1999; *pace* con Fintel and Gillies 2010), and nonveridical contexts in general. Now, notice that *tha* is fine with high probability adverbs such as *malon* ‘probably/most likely’, *sigoura* ‘certainly’ and *oposdhipote* ‘definitely’—but is bad with mere possibility adverbs such as *isos* ‘maybe/perhaps’ and *pithanon* ‘possibly’:

- (12) I Ariadne {malon/profanos/sigoura/oposdhipote} *tha* ine jatros.
the Ariadne probably/obviously/certainly/definitely FUTbe.3sg doctor.
Ariadne must {probably/obviously/certainly/definitely} be a doctor.

- (13) I Ariadne {isos/pithanon} **tha* ine jatros.
the Ariadne maybe/possibly FUT be.3sg doctor
Maybe Ariadne is a doctor.

This contrast suggests that the force of the modality of *tha* is stronger than mere possibility, and parallel facts about FUT and the adverbials hold in Italian (Giannakidou and Mari, to appear). Notice also that *tha* is compatible with a range of adverbs from high probability to necessity (*oposdhipote* ‘definitely’ which is the Greek equivalent to ‘necessarily’ in epistemic contexts).¹

The same behavior characterizes the Greek necessity modal *prepi* (the only necessity modal verb in Greek), which combines with the same range of adverbs, *but also with FUT itself*:

¹ The cognates *anagastika* ‘necessarily’ *ipixreotika* ‘obligatorily’ resist epistemic uses in Greek, and are preferred in deontic contexts. The sentence below creates an obligation that Ariadne be a doctor:

- (i) #I Ariadne *prepi anagastika/ipoxreotika* na ine giatros.
Ariadne must necessarily/obligatorily be a doctor.

The # marks the epistemic reading. In a context where an obligation makes sense, the use of *anagastika/ipoxreotika* is fine:

- (ii) Context: Ariadne wants to get a job at the hospital. I say: “In order to apply,
I Ariadne *prepi anagastika/ipoxreotika* na ine giatros.”
Ariadne must necessarily/obligatorily be a doctor

- (14) I Ariadne {malon/#isos} tha prepi na efije.
 Ariadne probably FUT must subj left.PNP.3sg
 ?Ariadne probably must have left.
- (15) I Ariadne (tha) prepi na efije.
 Ariadne FUT must subj left.PNP.3sg
 ?Ariadne probably must have left.
- (16) Ta pedia prepi oposdhipote na ine sto spiti.
 The children must definitely SUBJ be.3pl in-the home
Epistemic necessity: The children must definitely be at home
- (17) Ta pedia **prepiprofanos/endexomenos** na ine sto spiti.
 The children **must obviously/potentially** SUBJ be.3pl in-the home
Epistemic necessity: The children must probably be at home

(All complementation is finite in Greek, and modal verbs take subjunctive *na* complements). *Prepi* is compatible with a range of adverbs above a certain threshold of high probability reaching to necessity. In this, it differs from English where *must* resists modification by adverbs other than strong necessity modals (ex. 14, 15), (though such occurrences are not unattested, as David Lassiter communicated to me)². It seems plausible to say that Greek collapses the Kratzerian distinction between *should* (weak necessity) and *must* (necessity) in the same lexical item (unlike English). Soward counts as necessity seems to be ‘more flexible’ in Greek—a fact that can also be used to support measure function based theories of modality such as e.g. Lassiter 2011, as I will comment briefly at the end of the paper. At any rate, given the co-compatibility of *tha* and *prepi*, we must conclude that they express matching modalities. We can view this as a case of modal concord in the sense of the most recent discussion in Huitink 2012, an idea I develop further in section 4.2.

2.2 FUT plusperfective non-past: future *and* epistemic reading

The combination of FUT and the perfective non-past (PNP) gives the temporal reading:

- (18) O Janis tha ftasi stis 5 pm/avrio. (future)
 The John FUT arrive.PNP.3sg at 5 pm/tomorrow.
 ‘John {will/#must} arrive at {5 pm/tomorrow}.’

A paraphrase with *must* is pretty odd in this case. Notice also that we have the adverbials ‘at 5 pm’ and ‘tomorrow’. Without them, the epistemic reading is free to surface:

- (19) Context: It’s late, the weather is bad, and we know Ariadne is travelling. You worry, and I want to reassure you and say:
 Min anisixis. I Ariadne tha ftasi. (epistemic)
 Not worry.imperative.2sg. the Ariadne FUT arrive.PNP.3sg.
 ‘Don’t worry. Ariadne will arrive.’

² Dan Lassiter offers the following, corpus retrieved, examples with *must possibly* and *must perhaps*:

- (i) The Parish borders the North Downs and is on the edge of a designated Area of Outstanding Natural Beauty. Surrounded by this amazing countryside it offers outstanding views. Just stand at Eastwell Towers and gaze out towards the Wye Crown, *it must possibly be one of the finest views in the South East*.
- (ii) This book is an odyssey, a journey up through the mists of time from the remote past. It explores what *must perhaps be the most fundamental of all questions* - who we are.

In this case, I am expressing a certainty that Ariadne will arrive which I mean to be comforting. This is a reading that we also get with *will*.

The epistemic reading is also prominent with the evidential “*ipan*” ‘they say’:

- (20) *O Janis tha gini kala, ipan.*
the John FUT recover.3sg said.3pl.
‘John will recover, they say.’

Finally, consider the following example (from Holton et al. 1997):

- (18) *Kaθe proi tha sikothi, tha pji to kafedhaki tu, tha dhiavasi tin efimeridha tu, kai kata tis 8.30 tha fiji jia to grafio tu.*
‘Every morning he will get up, drink his coffee, read his newspaper and at approximately 8.30 he will leave for the office.’

This is a series of generic sentences, with no reference to the future—in Greek or in English. So, the ‘future’ reading of *tha*, in the absence of a definite adverbial such as ‘at 5 pm’ is never ‘pure’, never devoid of epistemic modality. I must mention Chiou’s 2012 analysis which agrees with my conclusion above that *tha* always contributes an epistemic modal semantic core, and further argues that “the future interpretations arise as implicatures related to the Levinsonian I- principle. In essence, it is proposed that future-time reference is an I- enriched interpretation of the modal base achieved at the level of communication and depends on pragmatic cues of speaker intentions.” (Chiou 2012: 35). In this account too, we find the future reading being not a semantic contribution of *tha* itself, but due to more general conversational principles.

According to Giannakidou and Mari (to appear), the future reading arises as a temporally specific reading *when the speaker is in possession of direct knowledge*. This typically happens when we have an adverb (future, as here, or past as in the examples next). When the adverb is present, it provides direct evidence about a time, and this time serves to constrain the temporal space for the location of the eventuality denoted by the VP. The future reading is simply the forward narrowing down of the time of the event denoted by the sentence. In other words, the future reading comes as a temporal domain restriction, and the sentence is not merely an assessment, but becomes a prediction (for more discussion and examples see Giannakidou and Mari to appear).

2.3 *Tha* with past: epistemic and conditional

Tha is possible with both perfective and imperfective past. The perfective past (PP) gives rise to an epistemic interpretation, pretty much like the one we saw with the imperfective present. The only difference is that we are now epistemically assessing a past event, just like with combinations of *must* with present perfect in English:

- (19) a. I Ariadne tha kimithike tora.
the Ariadne FUT sleep.PP.3sg now
Ariadne must have fallen asleep by now.
a I Ariadne tha milise xthes.
the Ariadne FUT talk.PP.3sg yesterday
Ariadne must have talked yesterday.

I know Ariadne’s habits, plans etc. So I can infer *now* that at some point prior to now, Ariadne fell asleep. Crucially, I am assessing the sentence at the present time—the utterance time, a fact consistent with the analysis of Giannakidou 2009 outlined in section 3.

Everything we said about the epistemic reading earlier holds fully here, including the adverb uses and co-occurrence with *prepi*:

- (20) I Ariadne (tha) prepi {malon/oposdhipote/*isos} na kimithike tora.
the Ariadne FUT must probably/definitely/maybe subj sleep.PP.3sg now
Ariadne must {?probably/definitely} have slept now.

So again, we have high probability plus modal concord. With *tha* and the imperfective past (IP), on the other hand, a conditional, possibly counterfactual reading arises (Iatridou 2000, Giannakidou 2009; Smirnova 2011b):

- (21) I Ariadne *tha* *efevge* *tora*.
 the Ariadne FUT leave.IP.3sg now
 Ariadne would leave now.

- a. *Ala dhen efije telika.*
 But she didn't actually leave.
 b. *Ke pragmati, ine sto treno.*
 And indeed she is in the train.

The counterfactual reading is an implicature: it is cancellable. But not so with the past perfect:

- (22) I Ariadne *tha* *ixe fiji*
 the Ariadne FUT had left.PERF.past
 Ariadne would have leave left.
 # *Ke pragmati, ine sto treno.* ‘#And indeed she is in the train’

It is reasonable to assume that the counterfactual reading is not a genuine compositional reading—in the sense that it is not derived from the meaning of past and imperfective. Rather, it seems plausible to treat it as an implicature that we get because we are not using the simple past. We can imagine the hearer thinking that if the speaker knew that Ariadne drank the syrop, they would have used the perfective form which is stronger because it conveys completion. They didn't, therefore the speaker must not know that Ariadne drank the syrop, hence the counterfactual inference.

So, to sum up: *tha* behaves like a high-end necessity epistemic modal. The future reading emerges with the verbal dependent form perfective non-past—and is not particular to *tha* in this case (it is also observed with the optative, subjunctive particles etc). I proceed now with the analysis of Giannakidou 2009 which explains precisely this case, and then augment it with a modal component for *tha*.

3. Giannakidou 2009: the dependency of the perfective non-past and the particles as *n*

In Giannakidou 2009 I made two claims which play a central role here in deriving the future reading with the PNP. The first claim was that the Greek PNP cannot make reference to the utterance time, as is usually assumed to happen with apparent present tenses. In other words, Greek nonpast does not function as a present tense. Instead, the PNP denotes an interval whose left boundary is a dependent (Giannakidou 1998), *non-deictic* variable *t*. The presence of such a variable renders an expression ‘polarity’ sensitive, and will limit its distribution:

- (23) *Non-deictic variables* (Giannakidou in press: (109))
 A variable *x* is non-deictic iff *x* cannot be interpreted as a free variable.

A non-deictic variable is a semantically and syntactically deficient object (for more on this see Giannakidou and Quer 2012) that *cannot* pick up contextual values by default, like regular variables do. An item containing such a variable will thus depend on another element in the sentence to be valued. I proposed the following semantics for PNP:

- (24) $\llbracket \text{nonpast} \rrbracket = \lambda P \lambda t P((t, \infty))$

This semantics is inspired by Abusch's (2004) analysis of *WOLL* as a substitution operator. According to Abusch, "in the substitution operator, *t* is a bound variable that corresponds to the tense argument of *will*

[which is n , coming from the higher PRES; clarification mine]. For a top-level occurrence of *will*, the effect is to substitute (n, ∞) for n " (Abusch, 2004:39). However, with the Greek nonpast we will not be able to do this substitution because, unlike *will*, which triggers PRES at the top level (Abusch 2004: (48)), the Greek nonpast cannot trigger PRES, and without it, t remains free at the top. But t is a dependent variable, and as such it cannot be left free. In this case, the structure becomes ill-formed:

The interval (t, ∞) lacks temporal orientation, because t is unvalued: it can only be interpreted as a bound or identified variable, and here there is nothing above nonpast to give it a value. The PNP form must therefore rely on another element in the sentence to give a value to t .

And here comes the second claim I made: given the dependent nature of nonpast it becomes necessary to introduce n in some other node in the clause, higher than TP. This is where the particles enter the picture: they are generated in nodes higher than TP and function as PRES, they provide the utterance time. So, the denotation of *tha* I gave in Giannakidou 2009 was simply n , which after combining with TP gives a value to the dependent variable t of the PNP:

(26) $\llbracket \text{tha} \rrbracket = n$

(27) $\llbracket \text{tha} \rrbracket (\text{TP} (29)) = \lambda t \exists e [\text{write}(j, e) \wedge e \subseteq (t, \infty)] (n) = \exists e [\text{write}(j, e) \wedge e \subseteq (n, \infty)]$

So, *tha* gives us n , so we now have n to identify t and replace it. The event will now be located at the interval that starts at the utterance time and stretches through infinity. This explains the possibility of future for the PNP, while saying that *tha* is NOT a future tense. The result is a future orientation, the event of writing will be located at the interval following n . As I said at the beginning, this happens also with the subjunctive particle and the optative, so the need to have particles is semantically motivated:

(28) $\llbracket \text{na} \rrbracket = n$

Na thus functions as PRES in a subjunctive clause, and this partly explains why *na* and *tha* do not co-occur (Giannakidou 2009, Roussou 2000): one of them would be redundant. Here n is introduced by the Mood head which hosts *na*. In the absence of a modal or adverbial or a question particle, at C^0 we have the operator that gives the illocutionary force of a request or a command: $\lambda p !p$. The optative, I will suppose, is located in C, as the imperative morpheme, and therefore gives the illocutionary force.

In other words, the particles in the Greek clause (and related particles in Balkan languages, I would suppose) ‘expand’ the verbal structure beyond the V itself, and function as PRES. Importantly, the particles are always linked, even in main clauses—since e.g. *na* is under the force operator— with a C position. There is more detailed consideration of all this in Giannakidou 2009 (see also Lekakou and Nilsen 2007 for discussion).

Kratzer posits two conversational backgrounds as arguments of a modal expression— the modal base and the ordering source. (Additional parameters can be set, such as a secondary ordering source, as suggested in von Fintel and Iatridou, or a choice function as in Matthewson et al. 2007). These two arguments derive a number of modal ‘forces’ and ‘flavors’. The modal base f is the factual background, and the ordering source g is a normative background. With FUT, the modal base is epistemic; specifically it is the set of propositions known by an individual, i.e. the speaker in an unembedded context. A proposition p corresponds to a set of worlds, namely, the set of worlds in which it is true. A set of propositions A corresponds to a set of sets of worlds, and its intersection to a set of worlds, namely, the worlds in which all of the propositions of A are true. So, our modal base will be the following, and the relevant individual will be the speaker:

$$(32) \quad \cap f_{\text{epistemic}}(w) = \lambda w'. w' \text{ is compatible with what is known by the speaker in } w$$

Now, the ordering source orders the worlds in the modal base with respect to how well they conform to a given norm or ideal (often sensitive to the context). Modal expressions of necessity like *prepi* and *tha* ‘must’ quantify over those modal base worlds that adhere to the norms in the ordering source as much as possible. The ordering source g , when applied to a world, gives the set of norms of that world, and this set determines a partial order $\leq_g(w)$ on set of possible worlds, as defined below:

$$(33) \quad \text{The ordering } \leq_g(w)$$

For all $u, z \in W$, for any $g(w) \subseteq \wp(\wp(W))$:

$u \leq_{g(w)} z$ iff $\{p: p \in g(w) \text{ and } z \in p\} \subseteq \{p: p \in g(w) \text{ and } u \in p\}$

The ordering states that for any pair of worlds u, z , u is closer to the ideal set by $g(w)$ if the set of propositions true in z is a *subset* of the set of propositions true in u . A necessity modal requires that for all worlds u of the modal base, there is a world v that comes closer to the ideal imposed by the ordering source, and in all worlds z closer than v to the ideal, the proposition p expressed by its complement is true: p is true in all of the most ideal worlds of the modal base. We can simplify this definition by making the so-called ‘limit assumption’, i.e., by assuming that there always are accessible worlds that come closest to the ideal. We can call these worlds $Bestg(w)(\cap f(w))$, following (Portner 2009), or $\max g(w)(\cap f(w))$, following Huitink. We obtain the following lexical entries for *prepi*, *tha* and *must*:

$$(34) \quad \text{For any world } w, \text{ and conversational backgrounds } f, g:$$

$\llbracket \text{prepi/ tha/ MUST} \rrbracket_{w,f,g} = \lambda q \langle st \rangle. \forall w' \in Best_{g(w)}(\cap f(w)): q(w') = 1;$

where $Bestg(w)(X)$ selects the most ideal worlds from X , given the ordering given by $g(w)$

Crucially, only in the *Best* worlds is p true, therefore the universal modal is nonveridical: the modal base is a non-homogenous space containing p and *non- p* worlds, as can be seen in the diagram below:

$$(35)$$

This explains why the modalized sentence even with a necessity modal, is ‘weaker’ than a non-modalized assertion: there are worlds in the modal base $\cap f(w)$ where p is not true, and the actual world may turn out to be one of those worlds. Just to make sure that we appreciate this, consider the following case:

namely that *tha* and *prepi* convey weak necessity, this use of expected. But since it is a combination of the elements we are discussing here, I do not consider it a lexical item itself (nor do von Fintel and Iatridou).

- (36) Context: Ariadne is sneezing, has a fever, watery eyes, etc.
 B: She must have the flu.
 a. *Prepi* na exi gripi.
 must subj have.3sg flu
 b. *Tha* exi gripi.
 must have.3sg flu

The doctor is assessing, and given what he knows (the symptoms, his knowledge of what the symptoms mean, the time of the year, etc) he is entitled to conclude that Ariadne has the flu. In the worlds compatible with his best knowledge/evidence, etc., this is his verdict. However, his modal base allows also for worlds in which Ariadne does not have the flu (*non-p*) but an allergy, or pneumonia. The doctor's judgment may be that these worlds are not the correct basis for forming his current diagnose, they are not best; but they are there in the modal base. The more of those *non-p* worlds the doctor allows, or the more he allows them to influence his judgment, the less certain he becomes. If the doctor wants to exclude *non-p* worlds, he must make the stronger statement without *must/ta/prepi*, that relies on a veridical epistemic space which is homeogenous: *all worlds* compatible with what he considers as the basis for his diagnose are *p* worlds. I summarize the distinction below (for more detailed discussion see my earlier works (Giannakidou 1998, 1999, 2006, 2011):

- (37) *Veridical and nonveridical modal space*
 (i) A modal space (a set of worlds) *W* is veridical with respect to a proposition *p* just in case all worlds in *W* are *p*-worlds. (*Homogeneity*).
 (ii) If there is at least one world in *W* that a *non-p* world, *W* is nonveridical. (*Non-homogenous space*).

All modals come with non-homogeneous, therefore nonveridical spaces (pace von Stechow and Gillies 2010); and do subjunctive selective verbs and indirect evidentials (see also Smirnova 2011). The idea of homogeneous and non-homogeneous modal space has also been expressed in terms of *diversity* in Condoravdi 2002.

This concludes our basic discussion of the modality of *prepi* and *ta*. I must also mention, finally, that there are differences between *ta* and *prepi*, most prominently (a) the fact that *prepi* is also a deontic modal (so it can be associated with a deontic modal base) unlike *ta* which is only epistemic, and (b) that *prepi* is indeed compatible with past tense (*e-prepe*). Temporally, *ta* retains present perspective, and never scopes below past (see also Giannakidou and Mari to appear). I will close now by very briefly addressing the role of the adverbs.

4.2 *Tha* and the role of adverbs: modal concord

Recall the range of adverbs that *ta* and *prepi* combine with. I will only give the example here with *ta*, and gloss it as MUST. I remind the reader that the possibility adverbs are excluded:

- (38) I Ariadne {malon/profanos/sigoura/oposdhipote/*isos/* pithanon} *ta* ine jatros.
 the Ariadne probably/obviously/certainly/definitely/maybe/possibly MUST be.3sg doctor.
 Ariadne must {?probably/obviously/certainly/definitely/} be a doctor.

(There may be slight differences between *ta* and *prepi* when we consider a wider range of adverbials, but this needs to be assessed at a later time, as in these core cases they appear to be similar. A corpus study, for instance, could be valuable). The question is: what is the function of the adverbs? The very fact that they range from weak to classical necessity suggests a flexibility of *ta* that we don't find with *must*—which is odd, or only marginally acceptable with *probably*. The adverb in Greek disambiguates, specifies, the exact force of the modal.

I will capture this disambiguation by following Huitink's (2012) most recent account of modal concord. Huitink argues that the adverbs "fill the ordering source argument slot" of the modal verbs. This means that the phenomenon involves matching, which I find very appealing. The modal *ta* and *prepi* are compatible

with the whole range of necessity meanings, and the adverb requires matching modality. With matching modality, the adverb narrows down the interpretation of the modal. Huitink specifies the meaning of adverbs such as Dutch *verplicht* ‘obligatorily’ and *misschien* ‘perhaps’ in the following way, where P stands for a modal operator that has already combined with a modal base (so P is of type ((s, (st, t)), (st, st))):

- (39) a. $\llbracket \text{verplicht} \rrbracket = \lambda P: P$ is universal. $P(\lambda w \lambda p.p$ is obliged in $w)$
 b. $\llbracket \text{misschien} \rrbracket = \lambda P: P$ is existential. $P(\lambda w \lambda p.p$ is known in $w)$

The idea is that *verplicht* combines with a modal verb, checks whether it has the right quantificational force, and then applies this verb to an ordering source which assigns to each world the set of propositions that are obliged in it.

We can pursue this analysis for Greek facts. The adverbs *oposdhipote* ‘definitely’ and *malon* come with the presupposition that they need to attach to a universal modal. *Tha* is a universal so they can combine with it; but *isos* and *pithanon* ‘possibly’ aren’t universal so the combination fails:

- (40) a. $\llbracket \text{malon/oposdhipote} \rrbracket = \lambda P: P$ is universal. $P(\lambda w \lambda p.p$ is known in $w)$
 b. $\llbracket \text{isos/pithanon} \rrbracket = \lambda P: P$ is existential. $P(\lambda w \lambda p.p$ is known in $w)$

When the argument of the adverb is not a universal, their combination is not defined, and therefore becomes odd. *Malon* and *oposdhipote* both consider known facts, but *malon* is weaker than *oposdhipote* ‘necessarily’ in expressing high probability (or weak necessity), and not classical necessity. Due to space, I cannot work out the details of weak necessity that are relevant here. A way to capture this, though, within the theories of modality I am assuming, is to say that the accessibility relation of *malon* accesses more facts and therefore allows less worlds in the modal base (following Portner’s discussion of deontic *should* and *must* (Portner 2009: chapter 2). This would entail that the adverb affects the accessibility relation directly, not just the ordering source.

For adverbs like *profanos* ‘obviously’, Huitink suggests to consider a stereotypical ordering source (following Kratzer’s human necessity), which will give us a proposition “less certain” than a proposition that is necessary with respect to all epistemically accessible worlds. Bare epistemic MUST would quantify over this latter set. In this way, Huitink claims, MUST OBVIOUSLY expresses a weaker quantification than bare MUST on its own. I believe this holds for the combinations *tha profanos* and *prepi profanos* in Greek too:

- (41) a. I Ariadne tha ine profanos jatros.
 the Ariadne MUST be.3sg obviously doctor.
 b. I Ariadne prepi profanos na ine jatros.
 the Ariadne MUST obviously subj be.3sg doctor.
 Ariadne must obviously be a doctor.
 c. I Ariadne tha prepi profanos na ine jatros.
 the Ariadne MUST MUST obviously subj be.3sg doctor.
 Ariadne must obviously be a doctor.

Notice the three way concord in the c example with *tha*, *prepi* and the adverb. Indeed these statements are weaker than the statements without *profanos*.

I must close this discussion soon, but the last thing I wanted to say is that, I think, the concord phenomena that we observe in Greek may serve to support measurement based approaches to modality like Lassiter 2011. Lassiter proposes a theory of modality where the modal sentences get their truth values by comparing the position of their proposition on a relevant scale to a *threshold* value (determined by context and the lexical semantics of the modal). In this assumption, a rough semantics of MUST will be the following:

- (42) $\llbracket \phi \text{ must be the case} \rrbracket^{M,w,g} = 1$ if and only if $\text{must}(\phi)$ is greater or equal to ϑ_{must}
 (Lassiter 2011: (1.6))

We have here a measure for what counts as MUST—the threshold value ϑ_{must} . This threshold may differ

from one language to another—recall that in English *must* is harder (though not impossible) with *probably*, but in Greek, combinations of *malon* with *prepi* and *tha* are common. So, the threshold for MUST in Greek is lower and includes weak necessity (or high probability).

Modal concord, in this frame, can be restated as specifying subspaces on the measurement scale, a guide of where to look for the numerical value of *tha p*: e.g. on a scale from 0 to 1, with *malon*, we must look at values of high probability, say between .8-.9; with *oposdhipote*, we only look at .99. The adverbs therefore serve as value restrictors, as probability restrictors, which I find a very promising way to think about their role. Another way to rephrase this idea is to say that the adverbs function as degree modifiers (thanks to Dan Lassiter for this suggestion). If modal adverbs are probability degree modifiers, the differences in acceptability as we move down the range of epistemic modals (ordered by strength) become similar to the contrast between *slightly damp/wet/#soaking* or *somewhat large/#enormous* or *totally #ajar/open*. The modal-adverbial relation becomes thus parallel to the degree modifier-adjective relation in establishing permissible and non-permissible combinations that rely on the combinatorial restrictions of the modifiers as they ‘match’ (or do not match) the probability space established by the modal operator. Though I cannot undertake the task of making this promising idea more concrete in the present paper, I hope to be able to do so in future work.

4. Conclusion

I have only scratched the surface, in this paper, of the rich patterns of modal concord in Greek, and on the interaction between necessity modals and temporality in this language. Certainly the facts that I was able to consider here deserve a more thorough and careful examination for a better understanding—and for better appreciating the consequences they may have for the various tools for linguistic modality that have been developed in the past few years, especially for the gradability and concord approaches to modality.

I hope to have conveyed in this paper that the study of Greek necessity modals such as *tha* and *prepi* can teach us valuable lessons about the linguistic realizations of necessity. *Tha*, a traditionally known ‘future’ particle, turns out to have a broad usage as an epistemic modal operator of weak and classical necessity. The future meaning emerges as a particular case of combining *tha* with the verbal dependent form PNP. The gradable (or flexible) modality range of *tha* enabled us to make reference to modal concord and, in the end, to probability measure approaches to modality. Probability measurements have been posited also in the analysis of evidentials—most prominently in the theory of McCready and Ogata 2007 for Japanese evidentials. Most of the examples in that paper are future oriented. This may be an accident, but maybe not. The relation of evidentiality and the future is explored further in Giannakidou and Mari to appear, where the idea of ‘measuring’ the evidence plays a key role.

Acknowledgement

I wanted to thank the organizers of the 10th *International Conference on Greek Linguistics*—Zoe Gavrilidou, Angeliki Efthimiou, Penelope Kambaki-Vougioukli, and Evangelia Thomadaki, at the Democritus University of Thrace—for inviting me for a keynote presentation, at what proved to be an exceptionally lively and exciting ICGL. The talk presented me with an opportunity to think substantially about the set of data presented here—and which surely deserve a much more careful and detailed examination than I was able to do in this paper. The audience at ICGL 10 provided very useful feedback and many thanks to Nikos Mathioudakis for his editorial assistance! Many thanks also to Tasos Tsangalidis and Michael Chiou, my students at the Modality Seminar this spring (2012) at the University of Chicago, where parts of this material was presented—and to Dan Lassiter for his suggestions and data from English, as well as Janneke Huitink for her comments. I hope to be able to discuss their suggestions more properly as this project grows. Finally, I wanted to thank my collaborator on this big project, Alda Mari, for very useful discussions on the future, epistemic modality and evidentiality.

PHRASEOLOGY: ITS PLACE IN THE LANGUAGE, IN THE DICTIONARY, AND IN NATURAL LANGUAGE PROCESSING

Igor Mel'čuk

Observatoire de linguistique Sens-Texte
University of Montreal, Canada

igor.melcuk@umontreal.ca

ABSTRACT

The paper introduces the concept of phraseme—that is, non-free, or selectionally constrained, phrase or clause—and characterizes the three major classes of phrasemes: idioms, collocations and clichés (the latter including an important subclass of pragmatemes). A finer classification of phrasemes is elaborated, based on the notions of compositionality of complex linguistic signs and that of the semantic pivot of a meaning. After this, are described the techniques used to represent phrasemes of all types in an Explanatory Combinatorial Dictionary and present three examples illustrating the use of this dictionary for difficult cases of translation involving phrasemes.

You can't BUY TIME or SAVE TIME common idioms
notwithstanding. You can only
SPEND TIME.

Eric Zorn, a columnist for the *Chicago Tribune*

1. Introduction

The expressions printed in small caps in the motto are examples of what is known as phrasemes; phrasemes of a language constitute its phraseology. Linguists agree that phraseology is extremely important for linguistic studies, but, quite unfortunately, they do not agree either on the exact content of the notion 'phraseology' or on the way phraseological expressions should be described and treated in linguistic applications, among others, in lexicography and Natural Language Processing [= NLP]. I will address these two points: Section 2 proposes a rigorous definition of phraseme, a characterization of the major classes of phrasemes and an exhaustive phraseme typology; Section 3 sketches the fundamentals of a lexicographic description of phrasemes, while in Section 4 I consider three examples of difficult cases of automatic translation where the solutions come from the proposed lexicographic description of one of phraseme classes (namely, collocations). Section 5 summarizes the most important points of the paper.

My theoretical framework is Meaning-Text Theory [= MTT]. I have to use certain of its notions and formalisms without explanation. For more on MTT, please consult Mel'čuk 1974, 1981, 1988a: 43-91, 1997 and Kahane 2003a.

Technical terms appear, on their first mention, in Helvetica.

2. Phraseology in the Language

The literature on phraseology is too huge to be reviewed here even cursorily; see, for instance, Cowie and Howarth 1996, and the collections Everaert *et al.* (eds) 1995, Cowie (ed.) 1998, Burger *et al.* (eds) 2007, and Anscombre and Mejri (eds) 2011. I will limit myself to Mel'čuk 1995 (a sketch of a theory of phraseology within the Meaning-Text framework) and the classics Bally 1909 and Weinreich 1969, which have most profoundly influenced my approach to phrasemes.

2.1 Two Main Families of Phrasemes: Lexical and Semantic-Lexical Phrasemes

A phraseological expression is a multiword utterance—that is, a linguistic expression formed by several lexemes syntactically linked in a regular way (in what follows, only multiword utterances are considered, which allows me to omit the modifier *multiword*).¹ The notorious expression *X kicks the bucket* \approx ‘person X dies of natural causes, I being flippant about X’ is syntactically and morphologically structured exactly the same way as all similar phrases of the form “Transitive Verb—DirO:” *kick the ball, hit John, squeeze her hand*, etc. Even the expression *kick the bucket* itself can mean ‘kick the bucket [full of dirty water]’! This expression is special, i.e. phraseological, only because of its “unpredictable” meaning. A phraseological expression, or phraseme, is thus an utterance featuring some unpredictable properties, i.e., a constrained utterance, or an utterance that is not free. Therefore, I begin with a definition of free utterance.

DEFINITION 1: FREE UTTERANCE

|| An utterance **U** is free, or non-constrained, if and only if [= iff] each of its lexical components Lis selected by the speaker strictly for its meaning and in conformity with its linguistic properties but independently of the lexical identity of other lexical components of **U**.

Corollary: Every lexical component of a free utterance **U** can be replaced by any of its (quasi-)synonyms without taking into account any other lexical component of **U**, and this replacement does not affect **U**’s meaning and grammaticality. In the phrase *select the word freely*, you can replace any component with no matter which of its synonyms and the meaning as well grammaticality is preserved: *choose the lexeme without constraint*.

DEFINITION 2: NON-FREE UTTERANCE = PHRASEME

|| An utterance **U** is non free, or constrained(= phraseologized), iff at least one of its lexical components Lis selected by the speaker as a function of the lexical identity of other component(s) of **U**.

In a non-free utterance **U**, at least one Lis selected depending on **U**’s other particular lexemes; such an utterance is called, as I just said, phraseme.

Corollary: In a phraseme, not every lexical component can unrestrictedly be replaced by any of its (quasi-)synonyms without affecting the phraseme’s meaning and grammaticality. In *kick the bucket* \approx ‘die’ you cannot replace any of the components: *boot the bucket* or *kick the pail* do not mean ‘die’.

A phraseme violates the freedom of selection of its lexical components on the paradigmatic axis of speech production, as the speaker is looking (in his mental lexicon) for appropriate lexical units. The selection activity proceeds in two stages:

- First, the speaker constructs his starting meaning; he selects the necessary simpler meanings and unites them into the meaning of his eventual utterance—that is, into its starting Semantic Representation [= SemR].
- Second, the speaker selects lexical units needed to express his starting SemR and unites them into the Deep-Syntactic Representation [= DSyntR] of the utterance.

Accordingly, two cases of violation of lexical selection freedom can be distinguished in the process of constructing an utterance.

The first case. The construction of the starting meaning ‘ σ ’ [= the SemR] of the utterance L(‘ σ ’) is free. To obtain ‘ σ ’, the speaker selects simpler meanings ‘ σ_1 ’, ‘ σ_2 ’, ..., ‘ σ_n ’ and puts them together in conformity with his needs and general rules of his language: the language does not specifically constrain the speaker’s semantic choices. But the lexical components of the utterance L(‘ σ ’) cannot be chosen freely: some or all of them are selected as a function of the others. The violation of the selection freedom takes place in the transition {SemR} \Leftrightarrow {DSyntR} and manifests itself in lexical constraints. Therefore, resulting phrasemes are called lexical (boldface in examples indicates the lexical components selected restrictedly): *kick the bucket*, *pull* [N_Y ’s] *leg* ‘lie [to N_Y] in order to have fun’ or Rus. *na golubom glazu* lit. ‘on a blue eye’ = ‘pretending to act honestly and sincerely’; *The rain is falling in torrents*, *It rains cats and dogs* or Rus. *Dožd’ l’ët kak iz vedral* lit. ‘Rain is pouring as from bucket’ and *prolivnoj dožd’* ‘torrential rain’ are typical lexical phrasemes.

¹ The term utterance is used here to refer to the set of linguistic expressions including (beside words) phrases, clauses and sentences, since a phraseme can be any of the above. I leave aside the phrasemes of the morphological level—that is, the phraseologized combinations of morphs within a wordform: *fight+er* ‘military plane...’ or *for+get*. For this family of phrasemes, or morphophrasemes, see, for instance, Beck and Mel’čuk 2011.

DEFINITION 3: LEXICAL PHRASEME

|| A phraseme is lexical iff its meaning is constructed by the speaker freely, but its lexical components L(all or some) are selected in a constrained way.

The second case. Not only the lexical composition of the phraseme is constrained, but also its meaning. To describe a real-world situation, the Speaker is forced by the language to select the starting meaning 'σ', and he cannot take an equivalent meaning 'σ'' or 'σ''' ('σ' ≡ 'σ'' ≡ 'σ'''). As a result, the utterance L('σ') is constrained semantically **and** lexically. This type of phraseme is thus "doubly" constrained: in the transition {ConceptR} ⇔ {SemR} (by semantic constraints) and then in the transition {SemR} ⇔ {DSyntR} (by lexical constraints). This is a semantic-lexical phraseme. A simple example is the sign *Wet paint*: Russian says in this context *Ostorožno, okrašeno* lit. 'Caution, painted' rather than *Syraya kraska* 'Wet paint' or even *Ostorožno, vykrašeno* (with a different aspect prefix); and in English it would be inappropriate to write on a sign *Caution, freshly painted*, although this is a perfectly grammatical and semantically correct utterance. Here the language prescribes the meaning to express in the given situation and its specific lexical expression.

DEFINITION 4: SEMANTIC-LEXICAL PHRASEME

|| A phraseme is semantic-lexical iff not only all its lexical, but also all the components of its meaning are selected by the Speaker in a constrained way.

In other words, a semantic-lexical phraseme is selected as a whole (just like idioms, see 2.3.1).

Examples: *in other terms/in other words; to make a long story short*; Rus. *inače govorja* lit. 'speaking differently', *koroče govorja* lit. 'speaking shorter' or *čto i trebovalos' dokazat'* 'Q.E.D.' [= Lat. *Quod Erat Demonstrandum*].

Thus, this major partition splits phrasemes into two main families: lexical phrasemes and semantic-lexical phrasemes.

2.2 Compositionality and the Semantic Pivot

To develop a finer typology of phrasemes, the notion of compositionality of linguistic signs is needed. Recall (for instance, Mel'čuk 1982: 40-41) that a linguistic sign *s* is a triplets = ⟨ 's' ; /s/ ; Σ ⟩, where:

's' is the signified, or informational content, most often a linguistic meaning;

/s/ is the signifier, or a physical perceptible signal, most often a string of phonemes (or characters);

Σ is the syntactics, or a set of data specifying the cooccurrence of *s* with other signs.

For instance, the noun AIRCRAFT is represented as a linguistic sign like this:

⟨ 'vehicle designed to fly...' -SG/PL;²/ɛʔrkɹæft/; Σ = noun, countable, Lexical Functions: *land*_(V), *take off*, *crew*, ... ⟩

Simple signs are combined into complex signs by the operation of linguistic union ⊕. For a particular language **L**, this operation is represented as a set of linguistic rules that tell us how signs must be united:

- The signifieds are united by putting the SemR of an argument into the corresponding argumental position of the corresponding predicate; for instance, 'quite(...)' ⊕ 'baby' ⊕ 'sleep(...)' = 'quiet(sleep(baby))'.
- The signifiers are united by juxtaposing the strings of phonemes and applying all necessary morphological operations; for instance, *deploy* ⊕ *re-* ⊕ *-ed* = *redeployed*.
- The syntactics are united by retaining the combinatorial data valid for the resulting complex sign; for instance, *L*_(V) ⊕ *-er*_(N) = *L*-*er*_(N), as in *sing+er*.

These are rather general rules; but the operation ⊕ covers all rules necessary for appropriate combination of signs of **L**, including all syntactic and morphological rules, etc.

DEFINITION 5: COMPOSITIONAL COMPLEX LINGUISTIC SIGN

|| A complex linguistic sign **AB** consisting of the signs **A** and **B** is compositional iff **AB** = **A** ⊕ **B**.

This means that, for the complex sign **AB** = ⟨ 'AB' ; /AB/ ; Σ_{AB} ⟩, its signified 'AB' must be equal to 'A' ⊕ 'B', its signifier /AB/, to /A/ ⊕ /B/ and its syntactics Σ_{AB}, to Σ_A ⊕ Σ_B.

² This notation indicates that the meanings of the grammemes SINGULAR and PLURAL belong to the signified of the stem of the lexeme AIRCRAFT: *This aircraft is...* vs. *These aircraft are...*

From Definition 5 it follows that compositionality is an absolute notion, which does not admit degrees: a complex sign is compositional or not. Compositionality concerns the three components of the sign independently; in this paper I will consider only the compositionality of signifieds, i.e., the semantic compositionality.

A free utterance is necessarily compositional: it is only thanks to this property that linguistic communication is possible. To master language **L** means to have in the brain a sufficient number of simple signs of **L** and the rules of the operation \oplus for **L**.

The selection of lexical units happens on the paradigmatic axis of language while their combination involves the syntagmatic axis. Taking into account the two axes of speech production guarantees that our characterization of phrasemes is exhaustive.

DEFINITION 6: SEMANTIC PIVOT (OF A MEANING)

Let there be meaning ' σ ' that is divided into two parts, ' σ_1 ' and ' σ_2 ' (' σ ' = ' σ_1 ' \oplus ' σ_2 ').

|| The part ' σ_1 ' of meaning ' σ ' is called its semantic pivot iff the other part ' σ_2 ' is a predicate of which ' σ_1 ' is the argument: ' σ ' = ' σ_2 '('' σ_1 '').

The semantic pivot of meaning ' σ ' is logically different from the communicatively dominant component of ' σ ', which is the minimal paraphrase of ' σ ' (Mel'čuk 2001: 29–31). Thus, in the meaning of the phraseme *take a shower* 'wash oneself under a shower' the semantic pivot is 'shower', while the communicatively dominant component is 'wash'. (The semantic pivot will be identified in the examples by shading.) Note that:

- 1) The semantic pivot of a multi-word expression **E** does not have to coincide with the lexical meaning of one of **E**'s components. Thus, in the phrase *private eye* 'private detective' the semantic pivot 'detective' is not lexicalized as such.
- 2) In many cases, the semantic pivot of an expression coincides with its communicatively dominant component, but this is not a reason to confound them.

The notion of semantic pivot will be used to sharpen the typology of phrasemes.

2.3 Major Classes of Phrasemes

Crossing the two dimensions—lexical vs. semantic-lexical constraints and being compositional vs. non-compositional—gives four logically possible major classes of phrasemes:

Nature of constraints \ Compositionality of phrasemes	non-compositional	compositional
lexical	IDIOMS	COLLOCATIONS
semantic-lexical	IMPOSSIBLE CLASS	CLICHÉS

Figure 1 The Three Major Classes of Phrasemes

However, one of these classes—semantic-lexical non-compositional phrasemes—cannot exist: if a non-free (= phraseologized) utterance **U_{phr}** is non-compositional, then it has, by definition, a “holistic” meaning that is associated with **U_{phr}** as a whole; therefore, this meaning cannot be constructed by the speaker for the occasion; therefore, it does not make sense to talk about constrained/non-constrained character of its construction.

As a result, a natural language has just three major classes of phrasemes: idioms, collocations and clichés.

2.3.1 Idioms

DEFINITION 7: IDIOM

|| A lexical phraseme is an idiom iff it is non-compositional.

An idiom is indicated in print by elevated half-brackets: ' ... '.

Examples: '*cheek by jowl*' 'in close association', '*The game is up*' 'your deceit is exposed', '*come to* [**N_X**'s] senses' 'become conscious again', '*put* [**N_Y**] *on the map*' 'make the place Y well-known', '*bull*

session 'long informal talk on a subject by a group of people', *'game of chicken'* 'showdown between two opponents where none is disposed to yield and both lose if they push the conflict to the end' Rus. *'ostat'sja s nosom'* lit. 'remain with nose' \approx 'X gets nothing in a situation where X is supposed to obtain something he wanted', *'sinij čulok'* 'bluestocking', etc.

An idiom can be characterized by the degree of its transparency/opacity: the degree to which its meaning includes the meanings of its components. Three types of idioms can be distinguished in such a way: full idioms, semi-idioms and quasi-idioms. All of them are non-compositional, but the degree of their transparency varies.

DEFINITION 8: FULL IDIOM

|| An idiom **AB** is a full idiom iff its meaning does not include the meaning of any of its lexical components:

‘AB’ $\not\supset$ ‘A’ and ‘AB’ $\not\supset$ ‘B’.

Examples: *'put [N_Y] through its paces'* 'to test Y thoroughly', *'go ballistic'* 'suddenly become veryangry', *'by heart'* 'remembering verbatim', *'bone of contention'* 'reason for quarrels or fights', Rus. *'jabloko razdora'* lit. 'apple of discord' = 'bone of contention', *'delat' nogi'* lit. 'do legs' = 'flee', *'polezt' v butylku'* lit. 'try.to.get into bottle' = 'stubbornly insist on something in a dangerous situation', etc.

DEFINITION 9: SEMI-IDIOM

|| An idiom **AB** is a semi-idiom iff its meaning 1) includes the meaning of one of its lexical components, but not as its semantic pivot, 2) does not include the meaning of the other component and 3) includes an additional meaning '**C**' as its semantic pivot: 'AB' \supset 'A', and 'AB' $\not\supset$ 'B', and 'AB' \supset '**C**'.

Thus, a semi-idiom is semi-transparent (or semi-opaque, depending on whether you are an optimist or a pessimist).

Examples: *'private eye'* 'private detective', *'sea anemone'* 'predatory polyp dwelling in the sea', Rus. *'mozolit' glaza'* lit. 'make.corns.on Y's eyes' = 'be too often or for too long before Y's eyes'.

DEFINITION 10: QUASI-IDIOM (= WEAK IDIOM)

|| An idiom **AB** is a quasi-idiom, or weak idiom iff its meaning 1) includes the meaning of both of its lexical components, neither as the semantic pivot, and 2) includes an additional meaning '**C**' as its semantic pivot:

‘AB’ \supset ‘A’, and ‘AB’ \supset ‘B’, and ‘AB’ \supset '**C**'.

Examples: *'start a family'* '[conceive the first child with one's spouse, [thereby] starting a full-fledged family]';

'barbed wire' '[artifact designed to make obstacles with and constituted by] wire with barbs [fixed on it in small regular intervals]'; *'lightning rod'* '[artifact designed to protect buildings against lightning—a [metallic] rod [fixed at the upper part of the building and grounded]]'.

2.3.2 Collocations

DEFINITION 11: COLLOCATION

|| A lexical phraseme is a collocation iff it is compositional.

Examples: *heavy ACCENT*, Rus. *sil'nyj AKCENT* lit. 'strong accent', Fr. *ACCENT à couper au couteau* lit. 'accent to cut with. the knife'; *soundly ASLEEP*, Rus. *SPAT' glubokim snom* lit. 'asleep with deep sleep'; *ARMED to the teeth*; *fasten* \langle = *buckle up* \rangle *the SEATBELT*, Rus. *zastegnut' PRIVIAZNOJREMEN'* lit. 'button.up seatbelt'; *leap YEAR*, Rus. *visokosnyj GOD* (the adjective VISOKOSNYJ is used only with GOD 'year').

A collocation consists of a base, lexical unit chosen freely by the speaker (shown in *SMALL CAPS*), and of a collocate, lexical unit chosen to express the intended meaning as a function of the base. A collocation is semantically compositional, since its meaning is divisible into two parts such that the first one corresponds to the base and the second to the collocate. The meaning of the base is always the semantic pivot of the collocation. For more on collocations in the Meaning-Text framework, see Mel'čuk 2003a, 2003b and 2004.

This should not be understood as implying that a collocate—taken as such, outside the collocation—necessarily has the meaning it expresses within the collocation. Thus, in the collocation

sit for an exam ‘undergo an exam’, the verb SIT expresses the meaning ‘undergo’; but in an English dictionary, the verb SIT does not have to carry this meaning: ‘undergo’ is not its inherent, but context-imposed signified.

In English, you **make** a decision, and in British English, you can also **take** it. For the same thing, French says **prendre** [= ‘take’] *une décision*, German—*eine Entscheidung treffen/füllen* [= ‘meet/fell’], Russian—**prinjat** [= ‘accept’] *rešenie*, Turkish—*karar vermek* [= ‘give’], Polish—**podjąć** [= ‘take up’] *decyzję*, Serbian—**doneti** [= ‘bring’] *odluku*, and Korean—*gyeoljeongeul haerida/naerida* [= ‘do (take/put down)’]. This clearly shows that boldfaced verbs are selected as a function of the noun meaning ‘decision’. If instead of DÉCISION a French speaker uses CHOIX ‘choice’ (*Jean a pris la décision de rester* lit. ‘Jean has taken the decision to stay’ E*Jean a ... le choix de rester* ‘Jean has ... the choice to stay’), he has to say FAIRE ‘make’ rather than PRENDRE ‘take’: *Jean a fait (*a pris) le choix de rester* ‘Jean has made the choice to stay’.

Collocations are extremely variegated and very numerous in any particular language (in the millions). Two major types are distinguished: standard and non-standard collocations.

Let there be a collocation “Base-**f**-Collocate,” where the collocate expresses the meaning ‘**f**’ as a function of the base: roughly, ‘**f**’(Base) = Collocate.

DEFINITION 12: STANDARD COLLOCATION

|| A collocation “Base-**f**-Collocate” is standard in language **L** iff the meaning ‘**f**’ meets simultaneously the following two conditions:

1. ‘**f**’ is applicable to many different bases and specifies many different collocates.
2. $L_i(\mathbf{f})$ —that is, the lexical units that express ‘**f**’—participate in Deep-Syntactic paraphrasing.

In other words, **L** has many collocations where the relation between the base and the collocate is **f** (here, “many” means at least several dozen or, better, hundreds) and which are actively exploited in DSynt-paraphrases.

Examples: so-called support, or light, verbs, such as those used with ATTACK_(N) in *On Friday, the rebels carried out an ATTACK on the port.* E*On Friday, the port came under the rebels’ ATTACK.* E*The (last) rebels’ ATTACK on the port came on Friday.* E*On Friday, the rebels attacked the port.* Or else intensifiers, as in *The rebels ATTACKED the port from all sides.* E*The rebels launched a large-scale ATTACK on the port.*

DEFINITION 13: NON-STANDARD COLLOCATION

|| A collocation “Base-**f**-Collocate” is non-standard, in language **L** iff the meaning ‘**f**’ is not applicable to many different bases and does not specify many different collocates (in the minimal case, it can apply just to one base and produce just one collocate) and does not participate in the DSynt-paraphrasing.

Examples: *leap YEAR*, where ‘**f**’ = ‘having 366 days’; *black COFFEE*, ‘**f**’ = ‘with no dairy product added’; *LAUGH*in [N_x’s] *sleeve*, ‘**f**’ = ‘trying to hide the fact of...’; *spiked HEELS*, ‘**f**’ = ‘long and thin’; etc.

The meaning ‘**f**’ corresponds to a Lexical Function, see below, 3.2.1.

2.3.3 Clichés

DEFINITION 14: CLICHÉ

|| A semantic-lexical phraseme is a cliché.

Examples: *If you’ve seen one, you’ve seen them all*; *Happy birthday to you!*; *no matter what*; *We all make mistakes*; *Will you marry me?*; etc.

A cliché is a compositional expression used for a complex meaning ‘σ’ that the language prescribes to use instead of an equivalent one ‘σ’’. Thus, in English we ask *What is your name?* and answer *My name is* [N] or *I am* [N]; Russians say *Kak vas zovut?* lit. ‘How do they call you?’ and *Menja zovut* [N] ‘They call me [N]’. The sentences *Kak vaše imja?* and *Ja* [N], the literal renderings of the English expressions, are fully understandable and grammatical, but not quite standard.

A cliché is characterized by its lexical anchor (or anchors), which is the lexeme(s) whose meaning(s) control(s) the use of the cliché: *What is your name?* and *Kak vas zovut?* ‘What do they call you?’ have NAME/IMJA as their anchor. (As we see in *Kak vas zovut?*, a cliché’s lexical anchor does not have to be explicitly present in the cliché.) In a dictionary, clichés are described under their lexical anchors.

The clichés of a language fall into two major subclasses depending on whether the meaning of the cliché under consideration is constrained or not by the extralinguistic situation in which the cliché is felicitously used. If it is the case, we have pragmatically constrained clichés, or pragmatemes; otherwise, the cliché is pragmatically non-constrained.

Pragmatically non-constrained clichés include several subclasses, of which I will mention two:

- Complex proper names, which have just one referent each : *The Old Testament* [**name of the first part of the Bible**], *Farewell to Arms* [**name of a novel by E. Hemmingway**], *The Moonlight Sonata* [**name of a piano sonata by Beethoven**], *City of Lights* [**nickname of Paris**], *Eternal City* [**nickname of Rome**] (Bosredon 2011).

- Proverbs, which state «eternal» truths: *A friend in need is a friend indeed*; *Fortune helps the brave*; *The end justifies the means*. (NB: Not every proverb is a cliché; some of them are not compositional—that is, idioms, such as *Every Jack has his Jill* or *When in Rome, do as the Romans do*.)

Pragmatically constrained clichés can be illustrated by the case of warnings printed on containers of perishable foods. English says *Best before...*, while in Russian, this will be *Srok godnosti...* lit. 'Term of validity...', in Polish, *Najlepiej spożyć...* lit. 'The best [is] to consume...', in French, *À consommer avant...* lit. 'To consume before...', and in German, *Mindestens haltbar bis...* lit. 'At least keepable till...'. All these expressions are fully constrained but compositional—that is, they are clichés. However, this is a particular type of cliché, since they are used only in a particular situation: as an official inscription [**on a container of perishable food fabricated for sale**]. The boldfaced indication in brackets is a pragmatic constraint on this cliché.

Pragmatic constraints are in principle applicable to any type of lexical expression—not only to phrasemes but to lexemes as well; here are examples:

pragmatically constrained

idioms	: <i>Break a leg!</i> 'Good luck!' [to a performer who is going on stage] (<i>I</i>) <i>copy that!</i> 'I understood you' [in a radio communication]
collocations	: <i>Wet paint</i> [on a sign]
clichés	: <i>No parking</i> [on a sign] <i>Enjoy your meal!</i> [to people starting a meal]
lexemes	: <i>Roger!</i> 'I understood you' [in a radio communication] Pol. <i>Smacznego!</i> lit. 'Of tasty!' ≈ 'May your food be tasty!' [to people

starting a meal]

However, among pragmatically constrained lexical expressions, clichés occupy a special place: a crushing majority of pragmatically constrained expressions are clichés. Therefore, it is convenient to give pragmatically constrained clichés a special name: pragmatemes.

DEFINITION 13: PRAGMATEME

|| A pragmatically constrained cliché is a pragmateme.

Examples: *Hold the line!* [**in a telephone conversation**], *Watch your step!* [**on a sign**], *X—all you can eat* [**on a sign in a restaurant**], *Emphasis mine* [**after a quotation in a written text**], *Return to sender* [**on a postal sending**], *Who's there?* [**answering a knock on the door**], *Enjoy your meal!* vs. Fr. *Bon appetit!* lit. 'Good appetite!' [**to people starting a meal**], etc.

Let it be emphasized: such a cliché as *What's your name?* is not a pragmateme: it can be used in any situation; likewise, *on top* [*of* Y], *Sorry to keep you waiting*, *I am in the mood* [*for* Y], *Would you mind* [*Y-ing?*], *It's a proven fact*, etc.

Here are a few Turkish pragmatemes (from Öztürk Kasar 2009: 168-175; they are given in a literal translation):

MARRIAGE

«I wish you both to age together
happily» : *May God allow you to age on the same bolster!* [**a wedding guest to the newlyweds at a marriage ceremony**]

WORK

«I wish you that your work be
successful» : *May this come easily!* [**a passerby to somebody who is working**]

MEDICINE [drug]

«I wish you that this cures you
medicine] : *May this be beneficial!* [**to somebody who is taking a**

SNEEZE

«I wish you everything good»

:*May you live long!* [to a person who sneezes]

SHOWER, BATH, SHAVING

«I wish you everything good»

: *May there be plenty of healths!* [to somebody who has just bathed or shaved]

showered,

SLEEP

«I wish you to sleep well»

: *May God give much comfort!* [to somebody who is going to bed]

Note that in Spanish, in this situation you wish *¡Buenas noches!* 'Good nights!', in Russian—*Spokojnoj noči!* 'Quiet night!', and in Serbian—*Laku noć!* 'Easy night!'

However, the Turkish clichés *May God give strength to your arms and your legs!* and *May your eyes burst!* are not pragmatemes, since they can be used in any circumstances to express the following conceptual content:

THANK

«I thank you for physical efforts
with which you have just helped me»

: *May God give strength to your arms and your legs!*

DAMN

«I damn you»

:*May your eyes burst!*

As noted by A. Polguère (orally), many—perhaps even the majority of—pragmatemes are independent utterances, i.e., sentences. Moreover, their meaning includes most often the meaning 'I' (= 'the Speaker'); therefore, they are non-descriptive lexical units, more precisely signalatives (Mel'čuk 2001: 353-356).

2.5 General Typology of Phrasemes

I can now present all the major subclasses of phrasemes and their taxonomy:

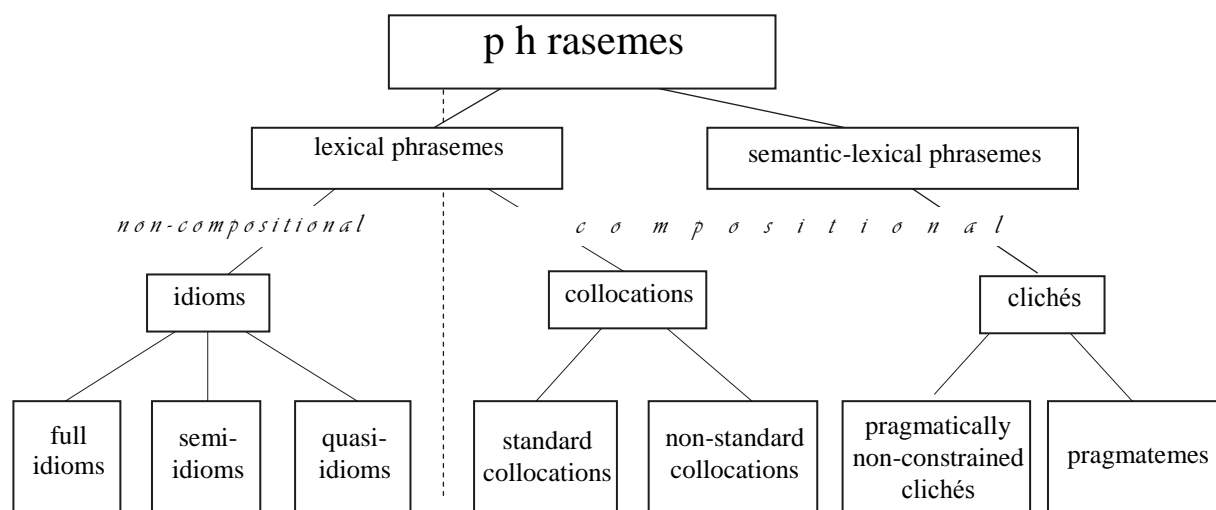

Figure 2 General Typology of Phrasemes

3. Phraseology in the Dictionary

The dictionary considered here is the *Explanatory Combinatorial Dictionary* [= ECD]; its principles, its structure and basic underlying notions are taken for granted (see Mel'čuk 1974, Mel'čuk and Zholkovsky 1984, Mel'čuk 1988b, Mel'čuk et al. 1984–1999, Mel'čuk et al. 1995, Mel'čuk 2006, Mel'čuk and Polguère 2007). I will discuss only the lexicographic presentation of phrasemes.

3.1 Lexicographic presentation of non-compositional phrasemes (idioms)

An idiom is a lexical unit, just as a lexeme is one. Idioms are, then, described in an ECD the same way as lexemes: each has its proper dictionary entry, featuring the same structure as a lexeme entry, with one important difference: since an idiom is a multiword utterance, it is supplied with its Surface-Syntactic structure. Cf.:

'PULL THE WOOL OVER [N_Y's] EYES', full verbal idiom

Definition

X pulls the wool over Y's eyes : 'X tries to deceive Y in order to hide from Y what X is really doing'.

Surface-Syntactic Structure

Government Pattern

$X \leftrightarrow I$	$Y \leftrightarrow II$	
1. N	1. <i>of</i> N	THE ← determ → EYES → attrib → OF N
	2. N's	EYES → possessive → N's
	3. A _(poss) (N)	EYES → determ → A _(poss) (N)

Don't pull the wool over foreigners' eyes! | *He tried to pull the wool over my(John's) eyes.*

The number of idioms in a particular language is probably around 10 000; thus, the English idiom dictionary Cowie *et al.* 1993 contains about 7 000 idiomatic expressions, and the French idiom dictionary Rey and Chantreau 1993, about 9 000; an excellent Russian-English dictionary of idioms (Lubensky 1995) presents some 13 000 idiomatic units.

3.2 Lexicographic presentation of compositional phrasemes (collocations and clichés)

Compositional phrasemes—collocations and clichés—are not lexical units; they do not have their own dictionary articles and are described in the articles of their bases/anchors. For instance, the collocation *ARMED to the teeth* does not have a separate entry, but appears under ARMED; Rus. *vypisat' čeklit*. 'write out a check' = 'draw a check' is given under ČEK; and so forth. The same is true of clichés.

3.2.1 Lexicographic presentation of collocations

The number of collocations in languages of *Standard Average European* type is very high: no less than ten times the number of lexemes, which means millions. Therefore, the lexicographic description of collocations requires a special formal apparatus that would allow for their elegant systematic presentation in the dictionary and, at the same time, facilitate automatic processing. Such an apparatus is the system of **lexical functions** [= LFs]. It is of course impossible to introduce here the notion of LF or offer the reader a detailed review thereof (see Žolkovskij and Mel'čuk 1967, Mel'čuk 1974: 78-109, 1982, 1996, 2003a, b, Kahane 2003b, Kahane and Polguère 2001, Wanner (ed.) 1996). I will limit myself to a few examples of standard and non-standard LFs, used for the description of, respectively, standard and non-standard collocations—in order to show afterwards how LFs can be exploited in NLP.

Standard collocations described by standard LFs

A standard LF **f_{stand}** describes a family of standard collocations where the semantic relation between the base and the collocate is institutionalized in the language; **f_{stand}** specifies this relation simply by its name.

• Verbal Standard LFs

– Support verbs

	RESPONSIBILITY X's ~ concerning Y	CARE X's ~ concerning Y	ACCUSATION X's ~ of Y of Z	AID X's ~ to Y
Oper ₁	<i>carry</i> [ART ~]	<i>give</i> [~ to N _Y]	<i>level</i> [ART ~ at N _Y]	<i>come</i> [to the ~ (→ of N _Y)]
Func ₂	~ <i>includes</i> [N _Y]	~ <i>is aimed</i> [at N _Y]	~ <i>weighs</i> [on N _Y]	~ <i>comes</i> [to N _X from N _X]
Labor ₁₂	————	<i>surround</i> [N _Y with ~]	<i>bring</i> [N _Y under ~]	<i>support</i> [N _Y with N _X 's ~]

– Realization verbs

	PRIZE X's ~ to Y for Z	DOCTOR ~ X of Y	TRAP X's ~ for Y	ASPHALT ~ used by X on Y
Real ₂	<i>win</i> [ART ~]	<i>see</i> [ART ~]	<i>fall</i> [into ART ~]	————
Fact ₂	~ <i>goes</i> [to N _Y]	~ <i>sees</i> [N _Y]	~ <i>catches</i> [N _Y]	~ <i>covers</i> [N _Y]
Labreal ₁₂	[N _Y of ART ~]	————	<i>catch</i> [N _Y with ART ~]	<i>cover</i> [N _Y with ~]

• Adjectival Standard LFs (intensifiers/mitigators)

	WET	DRUNK	BREATHE	ROLE	LAUGHTER
Magn	~ <i>to the bone</i>	<i>dead, stone~, ~ as a skunk//smashed</i> ³	~ <i>heavily</i>	<i>important < crucial < critical</i>	<i>hysterical, side-splitting ~; uncontrollable ~</i>

	WOUND	DRUNK	BREATHE	ROLE	LAUGHTER
AntiMagn	<i>light ~ //scratch</i>	<i>slightly ~ //tipsy</i>	~ <i>lightly</i>	<i>small, secondary ~</i>	<i>muffled ~</i>

Non-standard collocations described by non-standard LFs

A non-standard LF **f_{non-stand}** describes a non-standard collocation where the semantic relation between the base and the collocate is not institutionalized in the language; to specify this relation, **f_{non-stand}** must be described in the same metalanguage as that used for lexicographic definitions:

with no diary products added(COFFEE) : *black* [~]
drinking up the contents of the glass
at one go(DRINK) : [~] *bottoms up*
used too much(EXAMPLE) : *hackneyed* [~]

To illustrate the lexicographic description of collocations, here is a lexical entry for the noun BATTLE1(as in *Fierce battles are raging within 25 miles of Tangkin*):

BATTLE1, noun, countable

Definition

Battle between X and Y for Z: 'Armed confrontation between group X and group Y for Z'.

Government Pattern

X ↔ I	Y ↔ II	Z ↔ III
1. <i>of</i> N 2. N's 3. A _{poss} (N)	1. <i>with</i> N 2. <i>against</i> N	1. <i>for</i> N 2. <i>over</i> N 3. <i>to</i> V _{INF}
4. <i>between</i> N and N		

a battle of Philippino guerrillas/their battle

with (<= *against*) *the Japanese*;

battles between Palestinian factions for (<= *over*) *the border control* (<= *to control the border*)

Lexical Functions

Syn_∩ : *engagement < combat; action; fight; firefight*
V_o_∩ : *battle*_V
S_{1/2} : *combatant; adversary, enemy*
S_{loc} : *battlefield, battleground*

³ The symbol “//” indicates that all LF values that follow it are fused— that is, each one expresses together the meaning of the base and its own; thus *smashed* means ‘very drunk’. Another example: *Magn(fog) = dense, thick//pea-soup*, where *pea-soup* means ‘dense fog’.

Mult	: //hostilities; war
Loc _{in}	: in [~]
Ver	: winning[a winning ~]
AntiVer	: losing
Magn	: pitched; ferocious, fierce, grueling, intense, rude, violent; bloody<murderous [huge losses] <mortal; royal / postposed
AntiMagn	: //skirmish
Oper ₁	: fight [ART ~]; be, be locked, be engaged [in ART ~ →against N _Y]
IncepOper ₁	: engage [ART ~]
ContOper ₁	: continue [ART ~]
FinOper ₁	: stop [ART ~]
CausOper ₁	: send [N _X in ~]
[Magn+Func ₀]	: rages
Func ₁₊₂	: opposes [N _X to N _Y ; N _X and N _Y], pits [N _X against N _Y]
nonFunc ₀	: //guns are silent
IncepFunc ₀	: breaks out
IncepLabor ₁₂	: //engage [N]
Real ₁	: win [ART ~]
AntiReal ₁	: lose [ART ~]
Son	: rumbles
X and Y being individuals in physical contact	: close, hand-to-hand [~]
X and Y being ships	: naval
X and Y being planes	: aerial, air [~] //dogfight
X and Y being of quite unequal forces	: unequal; see-saw [~]
X and Y being of rather equal forces	: tight
more difficult for X	: up-hill [~]
X's first B.	: //baptism of fire
X begins to participate in B.	: joins [the ~]

3.2.2 Clichés

Being compositional, the meaning of a cliché need not be indicated in the dictionary. (Although in a pedagogical dictionary it might be.) What has to be indicated is the conceptual content to which a given cliché corresponds. Thus, for the content «I want you to tell me your name» (a conceptual representation is printed in «Monaco» in double quotes and is underlined), English says *What's your name?*, while in Russian the corresponding expression is *Kak vas zovut?* lit. 'How do they call you?', which has a different meaning—that is, a different semantic representation.

Clichés (including pragmatemes) and pragmatically constrained lexemes are presented in the articles of their anchor(s) in a way similar to the presentation of non-standard LFs, except that instead of the description of their meaning, the dictionary gives a description of their conceptual content. For instance:

PAY _(V)	
«without having to pay»	: free of charge
LATE	
«Even if this is happening later than needed, it is OK»	: Better late than never.
PUBLISH	
«[the text in question] is supposed to be published shortly»	: forthcoming [in a bibliographic reference]
DOG	
«There is an aggressive dog on premises»	: Beware of dog [on a sign]

3.3 New Type of General Dictionary

The proposed lexicographic description of phrasemes entails a new concept of general dictionary. Traditionally, a dictionary is a huge list of words supplied with all types of necessary or useful information. But if the dictionary also has to store and systematically describe all set phrases, which outnumber words at least 10 to 1, it ceases to be a dictionary of words: it becomes a dictionary of phrases or, more precisely, of minimal utterances—that is, utterances that cannot be fully represented in the lexicon in terms of other, smaller utterances and rules for their combinations. The idea that what is actually needed is a dictionary of multiword expressions was put forth in a concise article Becker 1975; coming from a different direction (language teaching), Nattinger 1980 also underscored the necessity of a “phrasal” dictionary. Bogusławski and Wawrzyńczyk 1993 and Bogusławski and Danielewiczowa 2005 constitute an excellent illustration of what such a dictionary should look like: their dictionary includes idioms, collocations and clichés, but also syntactic constructions (for instance, «N_X of N_{(period)Y}»: *book of the year* or *cover girl of the month*). More recently, many dictionaries of idioms and collocations have been published for different languages, but what I am aiming at here is a general dictionary where words and multiword expressions are stored and described together and in parallel. The ECD is intended to be such a dictionary.

4. Phraseology in Natural Language Processing

Idioms and clichés have to be listed in the dictionary, and I have shown how this could be done. From the viewpoint of NLP, they are similar to single words and can be dealt with in the same way as single words are. But the collocations pose a serious problem for automatic processing, in particular for automatic translation, given their number and variety. Lexical Functions offer a reasonable solution.

LFs can be used in NLP—in particular, in automatic translation and text generation—in two ways. On the one hand, LFs ensure correct lexical selection when translating the collocations of the type (English-Russian) *grave illness* ~ *tjažělaja bolezň* lit. ‘heavy illness’, *put* [N_Y] *in danger* ~ *podvergat*’ [N_Y] *opasnosti*_{DAT} lit. ‘submit [N_Y] to danger’ or *takeflight* ~ *obratit’sja v begstvo* lit. ‘turn oneself in flight’. All such “exotic” equivalences are covered by pairs of ECD-type dictionaries; LFs, being linguistically universal, play the role of an interlingua.

On the other hand, LFs underlie paraphrasing at the deep-syntactic level. This paraphrasing is necessary to resolve syntactic mismatches between the input and output sentences S_{source} and S_{target} , such mismatches being extremely frequent in parallel texts. Only paraphrasing can allow a translation system to construct an acceptable deep-syntactic structure for the output sentence S_{target} in the case of a serious mismatch between the vocabulary of S_{target} and its DSyntS, “inherited” from S_{source} . Thus, consider the sentence 0a) and its translations in Russian and French 0b-c):

- (1) a. *She competes internationally.*
- b. Rus. *Ona učastvuet v meždunarodnyx sorevnovanijax*
 ‘She participates in international competitions’.
- c. Fr. *Elle participe à des compétitions internationales* [idem].

The verb meaning ‘[to] compete’ (in the needed sense) does not exist in Russian or French. However, a verb V can always be paraphrased by the deverbal noun $S_0(V)$ and one of its support verbs: $V \Leftrightarrow S_0(V) \leftarrow \Pi - \text{Oper}_i(S_0(V))$. This formula describes all equivalences of the type *compete* \Leftrightarrow *participate in competition(s)*, *trip* \Leftrightarrow *take a trip*, *look* \Leftrightarrow *have a look*, etc.; the noun *competition* has direct equivalents in Russian and French.

For a universal DSynt-paraphrasing system, see Žolkovskij and Mel’čuk 1967, Mel’čuk 1974: 141-176, 1988c, 1992 and 2004, and Miličević 2007; Mel’čuk and Wanner 2006 deals specifically with the problem of syntactic mismatches in machine translation; the use of LFs in text generation is described in Iordanskaja *et al.* 1996 and Lareau and Wanner 2007. The paraphrasing system for Russian has been implemented and tested in a series of computer experiments: Apresjan and Cinman 1998 and 2002.

I will now present three examples of translation that are difficult because of the collocations involved, in order to show how the use of LFs ensures good results.

Example 1: The verb STRIKE

Take the sentence in 0a) and its closest (= most literal) Russian translation in 0b):

- (2) a. *The book thief struck again.*
- b. *Knižnyj vor снова соверšil kražu* lit. ‘Book thief again committed theft’.

It is absolutely out of the question to translate STRIKE in this sentence as UDARJAT' 'strike': the result would be incomprehensible. The correct choice is the collocation *soveršit' kražu* 'commit a theft'. But where and how do we establish the equivalence *strike* \equiv *soveršit' kražu*? In different contexts, the verb STRIKE has lots of other equivalents in Russian:

- (3) a. *The hurricane **struck** the island again.* \equiv
*Uragan snova **obrušilsja** na ostrov* lit. 'Hurricane again fell down on island'.
 b. *The bullet **struck** him in the shoulder.* \equiv
*Pulja **popala** emu v plečo* lit. 'Bullet hit to him in shoulder'.
 c. *A suicide bomber **struck** in the market.* \equiv
*Terrorist-smertnik **podorval sebja** na rynkelit.* 'Suicide bomber exploded himself in market'.

And so forth.

However, if we think of LFs, the answer comes immediately: all the illustrated uses of STRIKE are values of LF Fact_0 : $\text{Fact}_0(L) \approx$ 'perform the action that (the denotation of) L is supposed to perform in conformity with its nature'. A Russian ECD must have:

$\text{Fact}_0(\text{VOR 'thief'})$: *krast'* 'steal', *soveršat' kražu* 'commit a theft'
 $\text{Fact}_0(\text{URAGAN 'hurricane'})$: *obrušit'sja* [na N] 'strike [N]'
 $\text{Fact}_0(\text{PULJA 'bullet'})$: *popast'* 'hit'
 $\text{Fact}_0(\text{TERRORIST-SMERT-})$
 $\text{NIK 'suicide bomber'})$: *podorvat'sebja* 'explode oneself'

An English ECD gives the same indications for the above uses of STRIKE: $\text{Fact}_0(\text{THIEF}) = \textit{strike}$, etc.

Given the regular translation equivalents THIEF \equiv VOR, HURRICANE \equiv URAGAN, etc., the equivalencies between the corresponding values of their Fact_0 are obtained automatically.

Example 2: The French noun APPOINT 'exact sum paid by X to Y for Z such that Y does not have to give X any change' (= *exact change*)

A sign in a French bus shown in (4a) could be translated into Russian as (4b):

- (4) a. *Merci de faire l'appoint* lit. 'Thank you for doing the exact change'.
 b. *Platite za proezd bez sdačit* lit. 'Pay for transportation without change'.

Such an equivalent is produced, using a pair of dictionaries of the ECD type, in five steps.

- *Merci de Y* is a pragmatically constrained lexeme that must be described in a French ECD as a non-standard LF under PRIER 'ask':

«Authorities ask you to Y» : *Merci* [*de V('Y')*_{INF}] [*on a sign*]

- PRIER has a regular Russian equivalent PROSIT' 'ask'.

Under PROSIT', the Russian ECD has the above non-standard LF:

«Authorities ask you to Y» : *V('Y')*_{IMPÉR.2PL} [*on a sign*]

- *Faire* in 0a) is described in the French ECD as Real_1 of APPOINT:

$\text{Real}_1(\text{APPOINT})$: *faire* [*l'~*]

- APPOINT is translated as PLATA BEZ SDAČI lit. 'sum paid by X to Y for Z such that Y does not have to give X any change'.

- $\text{Real}_1(\text{PLATA 'the sum paid'})$: *//platit'* 'pay'

These five steps produce *Platite bez sdači* lit. 'Pay without change'. But Russian also requires the indication of the thing paid for: *platit' začto?* 'pay for what?' – *za proezd* 'for transportation'. This indication can be extracted from general knowledge about the situation in which the relevant utterance is made: if the sign is placed in a public transportation vehicle, you have to add *za proezd*; if it is hung on a ticket office, *zabilet* 'for ticket' is a must; if it is over the counter of a diner, it will read *za obed* 'for lunch'.

There is another way, perhaps even simpler, to establish the equivalence in question; namely, *faire l'appoint* can be described as a non-standard LF of PAYER:

giving the exact sum due, so that

Y does not have to give the change to X: *//faire l'appoint*

The corresponding non-standard LF in Russian is described under PLATIT' 'payer':

PLATIT' 'payer'

giving the exact sum due, so that

Y does not have to give the change to X : *bez sdačit* lit. 'without change'

The equivalence is then obtained in one step. Nevertheless, I wanted to present multiple paths that could lead to the same result.

Example 3: The verb STAB

The Russian sentence in 0a) must be translated into English as 0b):

(5) a. Rus. *Žertve bylo naneseno pjat' noževyx ran* lit. 'To.victim were dealt five knife wounds'.

b. *The victim was stabbed five times.*

Here are the steps necessary to obtain this equivalence:

- Rus. *Nanesti* [*ranu*] = CausFunc₂(RANA 'wound'); *noževaja* [*rana*] = caused by a knife(RANA)
- Eng. [caused by a knife + CausFunc₂(WOUND)] = // [to] *stab*
- A general Deep-Syntactic paraphrasing rule (i stands for a DSynt-actantial relation):

$$V_{\text{support}}(L_1) - i \rightarrow L_1 - \text{ATTR} \rightarrow L_2 \leftrightarrow V_0(L_1) - \text{ATTR} \rightarrow L_2,$$

that is, a modifier L_2 of the noun L_1 in a collocation "Support Verb + N" becomes a modifier of the verb that is semantically equivalent to this collocation; in our case, $\text{FIVE} \leftarrow [\text{STAB WOUND}_{\text{PL}}] \leftrightarrow \text{FIVE} \leftarrow \text{TIME}_{\text{PL}} \leftarrow \text{STAB}_{(\text{V})}$. (*Five times* is a surface lexical realization of the meaning 'five' when applied to a verb.)

5. Conclusions

In my view, the five most important points of this presentation are as follows:

1. Phrasemes constitute a very significant part of the lexicon of any language; therefore, they have to be presented in a formal dictionary (of the ECD type) in a systematic way.
2. A dictionary of the ECD type is the key for the automatic production of high quality texts.
3. Such a dictionary must reserve a place of honor for collocations described in terms of Lexical Functions as well as for all other phrasemes (idioms and clichés).
4. Lexical Functions must be exploited in two major respects: for lexical selection and for deep-syntactic paraphrasing.
5. A paraphrasing system must be part of any reliable NLP system.

Acknowledgments

The text of the paper has been read and criticized by D. Beck, L. Iordanskaja and J. Milićević, whom I thank *from the depth of my heart* [=Magn(THANK_(V))]. I also profited a lot from long and heated discussions concerning phrasemes with S. Kahane and A. Polguère. I did my best to account for their remarks and suggestions; but of course I *bear* [= OPER_i(RESPONSIBILITY)] the *full* [= Magn(RESPONSIBILITY)] *responsibility* for any mistake that survived their scrutiny.

NEOCLASSICAL WORD FORMATION IN ENGLISH AND THE ORGANIZATION OF THE LEXICON

Pius ten Hacken

Swansea University, UK
p.ten-hacken@swansea.ac.uk

ABSTRACT

Neoclassical word formation is a relatively peripheral phenomenon in English and many other languages. Therefore, its peculiarities can offer interesting insights in the nature of word formation. Against the background of Jackendoff's Parallel Architecture, an account of the historical development and basic system of neoclassical word formation is proposed. The central remaining problem is that this system is available for naming new concepts, but not productive in the same sense as syntax is. In order to explain this, it is proposed to introduce a separate word formation component that acts on rather than being part of the lexicon.

1. Introduction

In English and other European languages, neoclassical word formation constitutes a subsystem of the lexicon. Some typical examples are given in (1).

- (1) a. anthropomorphic
- b. hydrophobia
- c. mycophagous

The examples in (1) are typical because they consist of three elements. The final element is easily recognizable as a suffix, whereas the classification of the other two is less straightforward. They are special elements that have their origin in Ancient Greek and appear only in neoclassical word formation. I will call these here *neoclassical formatives* (NCFs). Some less typical cases of neoclassical word formation are the examples in (2).

- (2) a. allomorph
- b. anthropoid
- c. geodesy

The examples in (2) are special in three different ways. In (2a), there is no suffix corresponding to the final element in (1). In (2b), there is only one NCF, the same as the first in (1a). In (2c), the second NCF does not occur in any other combination than with *geo-*.

Neoclassical word formation appears not only in English, but also in other European languages. In languages such as German and French, the system of neoclassical word formation is largely comparable to the corresponding one in English, although the suffixes and sometimes the spelling are adapted. The existence of such corresponding systems makes it often all but impossible to determine in which language a particular word was originally formed. Arguably, this question is of rather limited relevance. If we take the perspective of a speaker of English, whether (1a) was a borrowing from French or a formation in English does not change its place in the mental lexicon. What is important is that it can be analysed on the basis of rules that are part of the English speaker's mental lexicon.

The generalization to other languages is not absolute, however. The situation in Greek is special, because Modern Greek is a descendant of Ancient Greek. As described in detail by Mackridge (2009), there have been various attempts to change the Greek vernacular, which had been influenced by other languages, by taking over and adapting Ancient Greek words and rules. These attempts have interacted with the tendency to borrow terms that had appeared in neoclassical word formation in other languages. For a comparison of Modern Greek and English neoclassical word formation, cf. Petropoulou (2009).

Here, I will only consider neoclassical word formation in English and languages where it behaves similarly.

Neoclassical word formation is interesting because of its marked nature. It is obvious that word formation is not organized around such special phenomena as neoclassical formation, so that any special properties that neoclassical formation exhibits must exploit the nature of existing mechanisms. Therefore, a precise characterization of these properties gives us additional power to distinguish between different analyses of word formation in general.

The rest of this article will be organized as follows. Section 2 gives an overview of the theoretical background assumed here, based on Jackendoff's (2002) Parallel Architecture (PA). Section 3 discusses how neoclassical word formation works. Finally, section 4 addresses the issue of productivity and formulates a proposal how the resulting analysis can be encoded in PA.

2. Lexicon and word formation in the Parallel Architecture

In Jackendoff's PA, the lexicon plays a central role in the formulation of thoughts and the comprehension of linguistic expressions. The components of PA and their connections are illustrated in Fig. 1.

Figure 1 Jackendoff's (2002) Parallel Architecture

In PA, an expression has a phonological, a syntactic, and a conceptual structure. They are parallel in the sense that they are each based on formation rules generating the structure and interface rules mapping between the three structures. This idea is opposed to frameworks where syntactic structure is taken as central, as in Chomsky's (1981) Government and Binding theory, and to frameworks where semantic and phonological structures are the only basic representations, as in Generative Semantics.

One of the advantages of the architecture in Fig. 1 is that it accounts for processing in a highly intuitive way. As described by Jackendoff (2002), the production of an utterance involves the search for appropriate lexical entries that express relevant concepts. Components of the conceptual structure trigger lexical entries that can be used in the formulation. A selection of these entries is then combined to formulate the thought that started the process. In understanding an utterance, the starting point is the phonological structure. In the case of written text, it depends on the reading fluency whether the orthographic representation takes the place of the phonological representation in Fig. 1 or is mapped onto this phonological representation.

Word formation comes into play when a concept does not match any existing lexicon entry. However, there are several other mechanisms that can be used for this purpose instead of word formation. A first alternative is to describe the concept by means of a combination of existing words. This does not normally change the lexicon, but it enables the communication to pursue by using (syntactic) rules and existing entries. Another way to solve the problem is to use an existing lexicon entry in a different sense. It is essential, of course, that the receiver of the message will be able to understand it. Therefore, the selected entry should have a sense that makes the intended concept recognizable, e.g. by metaphoric or metonymic reasoning. A third alternative to word formation is borrowing. In this case, a name from another language is adopted as or (in the case of calques) used as a basis for the formation of a new name. Compared to the alternatives, word formation can be characterized as the only way to solve the naming problem that is at the same time rule-based and extends the lexicon.

Lexical entries are the basic building blocks of the language, stored in the minds of its speakers. In Jackendoff's framework, an example of a simple lexical entry is (3).

- (3) a. <violin>
 b. N_[+Count]
 c. [Thing VIOLIN]

A speaker of English who knows the word *violin* will have something like (3) in their mental lexicon. The information in (3) consists of two parts: first, the contribution this entry makes to each of the three types of structure; and second, the fact that these three pieces of information are linked to each other. In (3a), the phonological information has been replaced by the corresponding orthographic representation for the convenience of printing. (3b) gives some syntactic information. It should be noted that the only way to distinguish *violin* and *car* is by looking at the other representations than syntax. This reflects the insight that they are syntactically indistinguishable. The conceptual information in (3c) only represents the part that can be mapped into linguistic expressions. For other purposes, a picture of a violin stored as a mental image, or a mental image of the sound it produces, would be more suitable. This would then serve as a prototype. Depending on the speaker, the prototype will have more or less detail and will also vary in the details added.

Jackendoff (1997) argues that much of the lexical information stored in a native speaker's mental lexicon consists of units that are larger than individual words. This insight is in line with Wray's (2002) idea of *formulaic language*. PA offers a particularly elegant solution for the encoding of multi-word units. As an example let us consider (4).

- (4) The teacher lost his temper.

The verbal expression used in (4) is usually given in dictionary format as *lose one's temper*. The contributions to the three different representations in PA could be formalized along the lines of (5).

- (5) a. <lose> <temper>
 b. [_S DP_i [_{VP} V [_{DP} D_i N]]]
 c. [INCH [BE ([X], [AT [ANGRY]])]]

In (5a), only the two words that are specific to the expression are given. Other words in (4) find their origin in other lexical entries. In (5b), a syntactic tree is given. Here the coindexation of *one's* with the subject is indicated by the subscripts on D and DP.¹ The meaning of the expression is summarized in (5c), which can be paraphrased as 'X starts being angry'. Although (5) specifies the contribution of the expression to each individual representation and implies that they are linked, a full representation should also give details on which components of the different levels are linked to each other. In (6), this information is added by means of indices.

- (6) a. <lose>_p <temper>_q
 b. [_S DP_i [_{VP} V_p [_{DP} D_i N_q]]]_m
 c. [INCH [BE ([X]_i), [AT [ANGRY]])]]_m

The indices *p* and *q* indicate where in the syntactic structure of (6b) the words in (6a) are located. The indices *i* and *m* link the variable X and the entire expression in (6c) to the corresponding parts of the (6b). As is typical of non-compositional expressions, the syntactic structure takes the role of a hinge between the phonological and conceptual structures in the sense that one set of indices links it to phonological and another to conceptual structures.

The architecture in Fig. 1 can be compared to the Saussurean model of the sign. Whereas Saussure only recognizes a phonological and a conceptual component of the sign, Jackendoff adds a syntactic representation. This solves the problem of encoding function words. An example is *it* in the sense used in (7).

- (7) a. It seems strange to assume this.
 b. It is unlikely that she will come.

¹ Jackendoff does not adopt functional categories and rejects the DP analysis as originally proposed by Abney (1987). However, in my view, the argumentation against the proliferation of functional categories of the type found in Pollock (1989) does not automatically extend to the DP analysis. After all, one of Abney's (1987) arguments is that the phrase *that house* can be replaced by *that* but not by **house*. However, nothing in this paper depends on the choice of D or N as the head of such phrases.

The information stored about *it* in the lexicon can be expressed as in (8).

- (8) a. <it>
b. Det, 3sing., Neuter
c. Ø

Whereas a Saussurean sign does not have a natural place to encode the syntactic information in (8b), it requires a *signifié*, a meaning associated with the form. In PA, there is no claim about each of the three representations having to be filled. For *it*, at least in its use in (7), it is plausible to assume an entry with no conceptual information, as indicated in (8c). However, if we accept both structure in a lexical entry, as in (6b), and empty slots as in (8c), we can also encode formation rules as lexical entries. An example is (9).

- (9) a. Ø
b. [_S DP VP]
c. Ø

What (9) encodes is the rule $S \rightarrow DP VP$, as used in the examples (4) and (7) to combine the grammatical subject with the verb phrase. Given that we have lexical entries such as (3), (6), (8), and (9), we can conclude that the lexicon in Fig. 1 includes both the linking rules and the formation rules. Jackendoff (2002) makes this point in more detail and with different examples. He shows that it is not possible to draw a principled boundary between formation rules and linking rules, by giving examples of various intermediate types of entries.

Fig. 2 does not include an obvious place for word formation. However, if all rules turn out to be lexicon entries, it is tempting to assume that the lexicon contains all of the information a speaker brings to their use of language in formulating and interpreting utterances and written language. This is also the hypothesis Jackendoff (2002) makes. Jackendoff (2010) elaborates this idea for word formation. In ten Hacken (2010), I proposed an alternative. As I hope to demonstrate, the analysis of neoclassical word formation provides an argument for the latter. Before describing the two theoretical options in detail, however, it is worth returning to the data of neoclassical word formation.

3. Neoclassical word formation

As an example for the analysis of neoclassical word formation, let us consider (1a), *anthropomorphic*. There are three questions to be answered about this word, listed in (10).

- (10) a. What are the basic elements of the word?
b. What is the structure of the word?
c. What are the rules involved in the formation of the word?

As we noted at the start, *anthropomorphic* consists of three elements. The final element is the suffix *-ic*. For the other two elements, we can use the data in (11) to determine their form and status.

- (11) a. anthropomorphic
b. philanthropic
c. morphotactic

A first observation regarding (11) is that *anthrop(o)* and *morph(o)* can each appear in first or in second position. Their semantic contribution is so similar that it would be unattractive to argue that *anthropo* in (11a) is not the same element as *anthrop* in (11b). In the same way, *morph* in (11a) is the same element as *morpho* in (11c). Although some dictionaries have separate entries for, for instance, *-phone* and *phono-*, e.g. COED (2011), such an analysis is not usually adopted in linguistic theorizing. The observation that these elements can appear in different positions implies that they are not affixes. At the same time, they are not normal stems. Neither **anthropo* nor **anthrop* can appear as a word in English (for *morph*, cf. further down). As mentioned in section 1, I will call them *neoclassical formatives* (NCFs) here.

A more difficult question concerns the status of the *-o-* at the end of the first element in (11a) and (11c). In general, it seems more attractive to assume that a final vowel is deleted in certain contexts

than that it is inserted. If we assume that *anthropo* and *morpho* are the base forms, we can easily devise a rule eliminating the final *-o* before *-ic* in (11b) and (11a), respectively. It is much harder to account for the putative insertion of *-o* in (11a) and (11c) if we assumed *anthrop* and *morph* as base forms. The first element in (11b) provides further evidence. The full form *philo*, as found in *philosophy*, is elided regularly before the initial vowel of *anthropo*. This means that it is not the second position, but the following vowel that triggers the loss of the *-o*. Therefore, we can answer (10a) such that we have the NCFs *anthropo* and *morpho* and the suffix *-ic*.

Turning now to (10b), we can in general have three possible structures for a form with three basic elements. They are indicated in (12).

- (12) a. [anthropo [_αmorpho -ic]]
 b. [[_βanthropo morpho] -ic]
 c. [anthropo morpho -ic]

The question of which structure is the best depends on the status of the intermediate constituents α in (12a) and β in (12b). Evidence for α or β supports the relevant structure, whereas in the absence of any supporting evidence, (12c) becomes attractive. At first sight, α may be attractive as an intermediate node because *morphic* is a word of English. However, there are two types of evidence against *morphic* as a constituent node of *anthropomorphic*. First of all, *morphic* does not have the right meaning. According to OED (2011), it is most frequent in the expression *morphic resonance*, the influence an entity is supposed to have on facilitating the genesis of similar entities by generating a ‘field’ in which the new entities ‘resonate’. Other meanings the OED gives are ‘of or relating to anatomical shape’ and ‘of or relating to animal or plant morphs’. Moreover, all of these meanings post-date the attestation of *anthropomorphic*. Whereas *anthropomorphic* was attested in 1827, *morphic* was first attested in 1868. This seriously weakens the case for (12a).

The support for (12b) cannot be based on the existence of **anthropomorpho* as a word of English. However, there are a number of words that contain this stem, OED (2011) gives *anthropomorphous* and *anthropomorphism*, and have a related meaning. The argument is reinforced by the observation that similar word families of semantically related words can be found for many other neoclassical formations. This means that (12b) is also more attractive than (12c). Therefore, there are good grounds to adopt (12b) as the structure of *anthropomorphic*.

In order to address (10c), we need to take a closer look at the history of the phenomenon. As Mayr (2004) argues, historical accounts generally take the form of a *narrative*, i.e. a plausible story that takes into account all available evidence. In the case of Mayr, the field is evolutionary biology. Lightfoot (1979) applies the same paradigm to historical linguistics (cf. ten Hacken, 2007: 317–24, for a brief discussion).

In the case of neoclassical word formation, we can distinguish three phases. In the first phase, individual items were borrowed from Greek and Latin. This can be illustrated on the basis of (13).

- | | | | | |
|------|----|------------------|---------------|------|
| (13) | a. | metamorphosis | μεταμόρφωσις | 1533 |
| | b. | anthropomorphous | ἄνθρωπόμορφος | 1753 |
| | c. | morphology | – | 1830 |

In (13), the English word is followed by the corresponding Ancient Greek word (where it exists) and the date of first attestation as given by OED (2011). When *metamorphosis* appeared in English, it was a borrowing from Greek, probably through Latin. Borrowings do not have the structure of the word as in the original language. Thus, whereas German *Kindergarten* is a compound, English *kindergarten* is a simplex noun. There are no English word formation rules that could account for its structure. The peculiarity of neoclassical word formation is that the structure of the borrowed words was reconstructed in the borrowing language.

When *morphology* appeared in English, at first in the field of geology, it could not have been borrowed from Greek, as shown in (13c), because there was no corresponding Greek word. What must have happened is that words such as (13a-b) were reanalysed as complex and *morphology* was formed by the components resulting from the reanalysis. Somewhere around 1800, a system of NCFs came into existence in English. This meant that (13a-b) were reanalysed as containing an NCF *morpho*, which from then on could be used to produce new items such as (13c).

The system of NCFs marks the second stage in the evolution of neoclassical word formation. The actual phenomenon is difficult to observe directly. We would have to determine whether particular word formation rules were part of the linguistic competence of particular speakers. The way we can observe the existence of the system of NCFs is by means of words such as *morphology*, which cannot

have been borrowed. Further evidence for the nature and strength of the system, as opposed to the individual NCFs, comes from the borrowing of NCFs. This phenomenon can be seen in the contrast between *morphology* and *psephology*. The meaning of *psephology* is ‘the statistical study of elections and trends in voting’ (COED, 2011). OED (2011) gives 1952 as the date of the first attestation. An interesting difference between *morphology* and *psephology* is that, whereas *morpho* originated from the reanalysis of borrowed items, as indicated in (13), no such analysis can be assumed for *psepho*. Ancient Greek *πηφός* means ‘pebble’. One of the derived senses develops this into ‘ballot’ (cf. Liddell & Scott, 1925). In 17th century English, we find *psephism* and *psephisma*, but they are only used in specialized contexts relating to ballots in classical Athens. OED (2011) also gives *psephomancy*, which exploits the ‘stone’ sense of the word. None of these are likely origins of *psepho* as used in *psephology*. A much more likely scenario is that someone looking for a learned name for the concept consulted an English-Ancient Greek dictionary to find the relevant stem. In this sense, *psepho* was borrowed into English as an NCF.

This second stage is not the end of the development. A number of words appear to combine NCFs with other lexical elements. Some examples are in (14).

- (14) a. pseudomodern, pseudomedieval
- b. gastropub
- c. webography, kremlinologist

In (14a), the NCF *pseudo* seems to combine with non-neoclassical adjectives. The most plausible analysis is that we do not see the same *pseudo* in (14a) as in, for instance, *pseudonym*. Rather, *pseudo* has developed into a prefix and it is this prefix that we see in (14a). This type of reanalysis of an NCF as an affix is relatively rare and only occurs for individual NCFs, not for large groups of them. A different type of phenomenon is seen in (14b). Here the NCF *gastro* seems to combine with the word *pub*. However, if *gastro* were the NCF in (14b), the meaning of *gastropub* should have ‘stomach’ as a component, cf. *gastritis*. In fact, COED (2011) gives the meaning ‘a pub that specializes in serving high-quality food’. Therefore, *gastro* can be explained much better as a clipping of *gastronomy*.² In (14c), we seem to have NCFs based on non-neoclassical elements. We will come back to these cases later.

In order to explain the neoclassical word formation system, we can choose one of two perspectives. In a diachronic perspective, the questions are how the neoclassical word formation system emerged and how individual NCFs developed. In a synchronic perspective, the central question concerns the nature of the system of neoclassical word formation. These perspectives cannot be separated entirely. In order to study the emergence of the system, we have to know its nature. This is the classical Saussurean argument about the relation between diachronic and synchronic linguistics. Perhaps more controversially, however, I would like to argue that it is also not possible to study the system of neoclassical word formation without knowing its historical development.

The central point here is that in order to come up with an account for the system, we have to decide which data should belong to the scope of the account and which can be excluded. In particular, not all words that contain NCFs belong to the system of neoclassical word formation. There are two other ways a word can contain an NCF. First, it can belong to the third stage of development, illustrated by (14). The borderline in this case depends on a comparison of the analysis as a neoclassical formation and alternative analyses. In (14a), there are good arguments to consider *pseudo-* a prefix. In (14b), an analysis as a clipping is better able to explain the meaning of the word. The best analysis of (14c) depends on how these examples fit with our general theory of neoclassical word formation.

Another type of explanation for the appearance of an NCF that does not depend on neoclassical word formation is that a word was borrowed from Ancient Greek before there was a system of neoclassical word formation. Whereas most words such as (13a-b) were reanalysed in the emergence of the neoclassical word formation system, there are also words that contain unique constituents, e.g. *geodesy* mentioned as (2c). This word was borrowed, but there is no sign that it was reanalysed, because the second element was never used in other words. Therefore, it is not necessary for an account of neoclassical word formation to include such cases as (14a-b) or (2c) in its scope.

For words that belong to the system of neoclassical word formation, I propose that they are formed on the basis of NCFs. An NCF is an element that does not have a syntactic category (cf. Petropoulou & ten Hacken, 2002). As a consequence, it cannot be used in syntax. Therefore, it cannot appear as a word in an expression of the language unless it undergoes an operation that turns the NCF into a word.

² As the ending of a clipping is not visible and there is no semantic distinction, it cannot be determined whether it is the noun *gastronomy*, the adjective *gastronomic*, or indeed the NCF *gastronomo* which has been clipped.

English has a number of word formation processes that do not impose on their input the condition that it has to have a syntactic category. In the case of *anthropomorphic*, the stages in its formation can be summarized as in (15).

- (15) a. anthropo, morpho → anthropomorpho
b. anthropomorpho → anthropomorphic

In (15a), two NCFs are combined into a compound that is itself an NCF. These NCFs do not have a syntactic category. In (15b), a suffix is added to the compound NCF and it becomes an adjective. The adjective is available for insertion into a syntactic structure. The sequence of steps in (15) reflects the structure as discussed above. It does not imply that *anthropomorpho* existed in a temporal sense prior to *anthropomorphic*. An alternative perspective on neoclassical word formation starts from an individual NCF. In (16), a number of different ways in which the NCF *morpho* can be input to neoclassical word formation are illustrated.

- (16) a. morpho → morph
b. morpho → morpheme
c. allo, morpho → allomorpho → allomorph
d. morpho, logo → morphologo → morphology
e. anthropo, morpho → anthropomorpho → anthropomorphic

In (16), only the final element of each line is a word with a syntactic category. All elements before the final arrows are NCFs without syntactic category. Compounding, as illustrated in (16c-e), is typical of neoclassical word formation, but (16a-b) show that it is not necessary. As (16d-e) illustrate, *morpho* can appear as either first or second element in a neoclassical compound. There are many NCFs that can only appear as the first element of a neoclassical compound. Fewer NCFs can appear as second or only element in neoclassical word formation. NCFs such as *bio* and *geo* only appear as first element, even though their meaning is clearly that of a stem. The flexibility of *morpho* is also shown by its possibility to appear in conversions, (16a) and (16c). In conversion, the thematic vowel is lost. This indicates that the thematic vowel has a different status with respect to the NCF than its other constituent phonemes.

At this point, I would like to return to the examples in (14c). The question about these cases is whether they are neoclassical compounds with an unusual first element or words with a different origin that happen to include an element that is used as an NCF in other words. If they are neoclassical compounds, we have to assume that there is a third way NCFs can come into existence, apart from reanalysis of borrowings (as *morpho* from *metamorphosis*) and direct borrowing (as *psepho* in *psephology*). This third way consists of the addition of what in regular NCFs is the thematic vowel to an existing word in English. This would then result in the steps in (17).

- (17) a. web → webo
Kremlin → Kremlino
b. webo, grapho → webographo
Kremlino, logo → Kremlinologo
c. webographo → webography
Kremlinologo → Kremlinologist

Whereas (17b-c) correspond to the regular steps in neoclassical word formation in (15), the step in (17a) is a more contentious assumption. However, we can only decide how attractive this assumption is by comparing it to alternative analyses.

One such alternative is that we are dealing here with suffixation. As illustrated in (14a), the reanalysis of an NCF as an affix is attested for other NCFs. In the examples in (14c), the resulting derivations would involve the suffixes *-ography* and *-ologist*. There are at least two arguments against such an analysis. First, the suffixes have an unusually rich and specific meaning. We find the definitions in (18) for the words in (14c).³

- (18) a. *Webography*: a list of websites that pertain to a given topic.

³ The definition in (18b) is compiled from the OED (2011) definition of *Kremlinologist* ‘such an analyst’ and the one for *Kremlinology*. The OED (2011) gives *webliography* but not *webography*. The definition in (18a) is from the Wikipedia (en.wikipedia.org/wiki/Webography, last modified 21 February 2012).

- b. *Kremlinologist*: an analyst of the Soviet Government, and subsequently the Russian government, and their policies.

If we assume that *-ography* is a suffix, it has to contribute a large part of the meaning of (18a), because *web* only has a very small part in it. Such a distribution of meaning between the components is not so uncommon for compounds. Indeed, Jackendoff (2009) develops his system for expressing the meaning of compounds on the assumption that the relation between the components is produced by a generative system, so that relations of an in principle unlimited complexity can be generated. However, if *-ography* is a suffix, such possibilities are not readily available.

The hypothesis that *-ologist* is a suffix in (18b) has another problem. Here we have a family of words of a type that is familiar from neoclassical word formation. Alongside *Kremlinologist* we have *Kremlinology* and *Kremlinological*. It is not attractive to assume that there are separate suffixes *-ologist*, *-ology*, and *-ological*, because the highly specific meaning of the words they form is very similar. When we try to solve this by analysing *-ologist* into two suffixes, *-olog* and *-ist*, we are in the process of creating a parallel system to neoclassical word formation, with *-olog* taking on the role of a neoclassical stem. Therefore, an analysis of (18) as suffixation rather than NCF formation is not attractive.

Another alternative analysis of (18) is in terms of analogy. For (18a), there is an alternative, *webliography*, which is formally more similar to *bibliography*. Both *webliography* and *webography* are used, although a Google search (16 March 2012) gave a 10:9 preponderance in the number of hits for *webography* over *webliography* (497,000 vs. 447,000). The form of *webliography*, in particular the *-lio-* component, cannot be explained otherwise than by analogy with *bibliography*. By contrast, *webography* is less clearly analogical and can readily be explained along the lines of (17). For *Kremlinologist*, the basis of the putative analogy is less obvious. The formation of *Kremlinology* and *Kremlinological* took place at about the same time. OED (2011) gives dates of first attestation ranging from 1958 to 1961 for the three words. Therefore, the idea of an underlying compound NCF is much more attractive.

In sum, there are good reasons to assume (17) as the analysis of the examples in (14c). This analysis brings them within the scope of neoclassical word formation and assumes that the formation of NCFs on the basis of non-neoclassical elements is a possible origin of new NCFs.

4. Productivity

The notion of productivity has been a central pillar in all frameworks of generative grammar. At a time when the focus of the discussion in American linguistics was the opposition between Post-Bloomfieldian approaches and the emerging generative approach, Chomsky formulated the issue as in (19).

- (19) The central fact to which any significant linguistic theory must address itself is this: a mature speaker can produce a new sentence of his language on the appropriate occasion, and other speakers can understand it immediately. [Chomsky (1964: 7)]

The view in (19) is not entirely new. In fact, Schultink's classical definition of morphological productivity in (20), although formulated without reference to a generative framework, is very much in line with (19).

- (20) Under productivity as a morphological phenomenon, we understand the possibility for language users to create new formations unintentionally and in an in principle not countable number, by means of a morphological procedure that is at the basis of the form-meaning correspondence of some words they know. [Schultink (1961: 113), my translation PtH]⁴

The central properties shared by (19) and (20) are the ideas of an infinite number of new expressions and their regular, unintentional formation. This type of productivity can be expressed in a very natural way in the PA framework of Fig. 1. It leads first of all to syntactic expressions, i.e. expressions that are

⁴ Original Dutch: "Onder produktiviteit als morfologisch fenomeen verstaan we dan de voor taalgebruikers bestaande mogelijkheid door middel van het morfologisch procédé dat aan de vorm-betekenis-correspondentie van sommige hun bekende woorden ten grondslag ligt, onopzettelijk een in principe niet telbaar aantal nieuwe formaties te vormen."

not stored in the lexicon, but constructed on the basis the combination of information in lexical entries. It is not surprising that a school of linguistics taking (19) as its point of departure would concentrate on syntax.

Jackendoff (2002) takes as a point of departure that what constitutes a lexical entry is an empirical question. Each speaker has their own lexicon. As ten Hacken & Panocová (2011) demonstrate, this is entirely compatible with the view that a particular word has a specific meaning in a speech community. However, we have to acknowledge that there are two different routes to becoming a new entry, which we might label ‘performance-based’ and ‘onomasiological’.

Jackendoff assumes that frequently used combinations are stored as entries because retrieval from the lexicon is more efficient than on-line construction from different lexical entries. Someone working at a supermarket till will have a repertoire of frequently used phrases stored in their lexicon, whereas customers may construct them. This does not affect successful communication. Jackendoff (2002) makes the point that this is also the case for productive morphology. In the case of English word formation, we might think of the formation of nouns in *-ability* on the basis of adjectives in *-able* in these terms. This is the performance-based route to lexicalization. Clearly, neoclassical word formation is not productive in this sense. When we characterize the productivity of neoclassical word formation, we can summarize it in the two observations in (21).

- (21) a. Neoclassical word formation is available for naming new concepts.
- b. Neoclassical word formation is not applied unintentionally.

If we want to consider neoclassical word formation productive on the basis of (21a), we need a new concept of productivity, which is compatible with (21b). Corbin’s (1987) analysis of productivity is interesting in this respect. She does not refer to unintentional rule application as in (20) and does not align it with syntactic productivity as in (19). Instead, she distinguishes three interpretations of “productivity”, and explains them as in (22).

- (22) a. *régularité*: predictability of form and meaning of the output
- b. *disponibilité*: availability of a rule for new formations
- c. *rentabilité*: extent to which a rule can be applied to many bases and have many outputs

It is interesting to compare (20) to (22). It is not possible to quantify productivity in Schultink’s sense in terms of (22c) directly, because the crucial point for Schultink is that the number is not finite, not that the number is high. His unintentionality is not adequately covered by (22a), although the two point in the same direction. The crucial difference seems to be that Corbin (1987: 177) goes on to argue that (22b) is the central sense of productivity, whereas Schultink’s definition in (20) imposes additional constraints on the concepts in (22a) and (22c). It is easy to see that (22b) is logically prior to the other two senses of productivity. Whereas (22a) and (22c) target rule application, (22b) is about the existence of a rule. Therefore, Corbin’s sense of productivity is weaker, less restrictive, than Schultink’s.

Corbin’s (22b) is eminently compatible with the scenario of finding a name for a new concept. This is the starting point of the analysis of word formation in Štekauer’s (1998, 2005) onomasiological approach. This scenario differs from performance-based, unintentional lexicalization in the sense that speakers are generally aware of their name-giving activity. This is also what is intended in (21a). Therefore, neoclassical word formation is productive in Corbin’s sense (22b), but not in Schultink’s sense (20). Lexicalization of neoclassical formations takes place according to the onomasiological scenario, not the performance-based one.

Whereas the PA framework accounts for productivity in the sense of (19) and (20) naturally and without further assumptions, the onomasiological route to new entries is not straightforward in Fig. 1. Jackendoff (2010: 34) mentions the issue of what he calls “semiproductivity” as “one of the central issues of linguistic theory for the coming years.” Earlier, Jackendoff (2002, 2009) proposed to account for it by means of redundancy rules that are *emergent*. This means that they are not rules that can be applied to produce new expressions, but only generalizations that facilitate storage and recall of existing expressions. If neoclassical word formation is a set of redundancy rules, each new form is produced by a kind of analogy. Jackendoff (2010: 28-34) proposes to encode semiproductive rules as lexical entries with a special feature that stops them from being applied freely. However, this system is meant also for the analysis of groups of words such as *receive*, *perceive*, *conceive*, etc. Such rules are not available in English and do not apply to items that can be described as complete lexical entries. The crucial difference between **ceive* and **anthropo* is that the latter has a meaning and can be used in new words, whereas the former does not have a meaning and only emerges as a formal component of some

borrowings. The reanalysis step that characterizes neoclassical word formation has not taken place for **ceive*.

A more attractive option is to modify the PA in such a way that it can accommodate the contrast between the different notions of productivity. Therefore, I propose to adopt the architecture in Fig. 2.

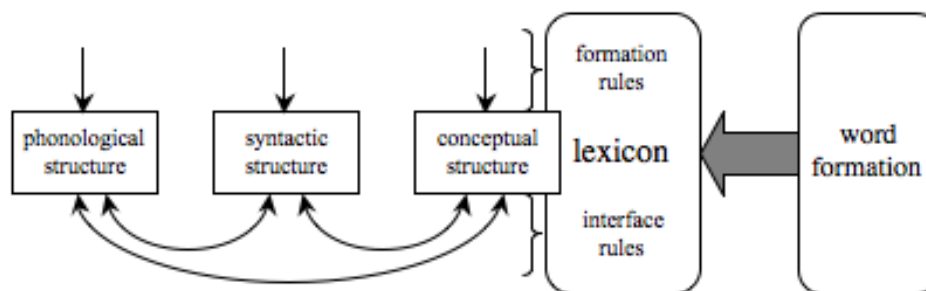

Figure 2 Modified Parallel Architecture

Compared to Jackendoff's version in Fig. 1, the architecture in Fig. 2 distinguishes between the lexicon and the word formation component. This means that productivity in the sense of Chomsky's (19) and Schultink's (20) can be encoded as entries in the lexicon, whereas productivity in the sense of Corbin's (22b) *disponibilité* can be encoded as rules in the word formation component. Where rules are not available for new formations, they are not encoded in either, which corresponds to Jackendoff's (2002, 2009) redundancy rules. In terms of ten Hacken & Panocová's (2011) distinction, the performance-based route to lexicalization involves (only) the lexicon, whereas the onomasiological route (also) involves the word formation component. Neoclassical word formation is a very clear example of a set of rules that belong in the word formation component.

SELECTING A THEORETICAL FRAMEWORK FITTING ACQUISITION DATA IS NO EASY MATTER

Ursula Stephany
University of Cologne
stephany@uni-koeln.de

Abstract

The question addressed in this paper is how to select an appropriate theoretical framework for describing acquisition data so that the description may contribute to an explanation of the acquisition process. The major current theoretical approaches to language acquisition to be taken into account are the functionalist, usage-based approach founded in cognitive linguistics and the nativist, generative Universal Grammar approach whose basic assumptions concerning human language are diametrically opposed to each other so that their consequences for theories of language acquisition differ in fundamental ways. In comparing the two approaches to language acquisition it will be argued that a constructivist, usage-based approach seems to be more appropriate than a nativist, generativist theoretical framework for explaining the empirical results gained so far in the domain of inflectional development in Greek child language acquisition.

Keywords: Theories of first language acquisition; Usage-Based Theory; Generativist Theory; acquisition of inflectional morphology; acquisition of Greek

1. Introduction: What is science?

As pointed out by Ströker (1987: 86-87) and other philosophers of science, there is no ‘pure’ experience, since experience and its scientific interpretation require a theoretical framework in which such an interpretation can be achieved. A precondition for interpreting empirical data is therefore to ask questions. These must be based on the state of the art in a given scientific domain and will lead to conjectures or hypotheses to be checked empirically. Hypotheses stay valid as long as they have not been empirically refuted. If refuted, new hypotheses must be advanced. The course of science may therefore be considered as a series of conjectures and refutations (Popper 1962). Hypotheses or entire theories cannot be verified, but only falsified. Therefore, it is doubt, rather than truth, which is at the center of scientific endeavor. Most importantly, the method of falsification serves to find and test more efficient scientific theories (Popper 1934/1971) and therefore has a constructive rather than a destructive function.

The two major currently competing theoretical approaches to child language acquisition are the nativist, generativist approach based on Chomsky’s ideas on Universal Grammar and the non-nativist, constructivist, usage-based approach. In section 2 of the paper, these approaches will be briefly compared and in section 3, the comparison will be narrowed down to the single- vs. double-route processing model of inflectional acquisition. In section 4, evidence for the single-route model in the acquisition of Greek nominal and verbal inflection will be provided. We hope to be able to demonstrate that the Usage-Based theoretical framework is not only apt to describe the acquisition data, but that it significantly contributes to our understanding of the acquisitional process.

2. Generativist vs. constructivist approaches to child language acquisition

As far as falsifiability is concerned, it is currently not clear whether the generativist or the constructivist theoretical approach to language acquisition meets this criterion since it has not been discussed in either of the two theories (Tomasello 2004; Ambridge & Lieven 2011: 376).

A precondition for being refutable is that a hypothesis or theory be precisely formulated. This is not the case for the Universal Grammar hypothesis, since more than seven different proposals of UG are found in the literature (Tomasello 2004: 642-643; see also Tomasello 2010: 313). Generativists are not

usually concerned with the falsifiability of the UG hypothesis and simply assume that UG exists or they try “to provide confirmatory evidence for it” (Tomasello 2004: 643). A more fundamental problem with the UG hypothesis is that it is not clear what kind of evidence could refute it (Ambridge & Lieven 2011).

The UG hypothesis has grown more and more abstract in the history of Chomsky’s formal approach to language (Tomasello 2010: 312). According to Chomsky’s more recent publications (Hauser, Chomsky & Fitch 2002: 1569 and Chomsky 2007), the two specifically linguistic computational principles which seem to have survived are recursion and merge. While considering recursion as “the only uniquely human component of the faculty of language,” Hauser, Chomsky & Fitch (2002: 1569) admit “that FLN [faculty of language in the narrow sense, U.S.] may have evolved for reasons other than language, [and that] hence comparative studies might look for evidence of such communication (for example, number, navigation, and social relations).”

Tomasello (2010) considers recursivity as a fundamental principle in the evolution of specifically human cooperative communication, which he shows to be more complex than the intentional communication also found in great apes, the difference being that, in human cooperative communication, there is not only individual intentionality, but in addition shared intentionality. According to Tomasello (2010: 321), “the basic cognitive skill of shared intentionality is recursive mindreading” which “generates joint goals and joint attention.” Recursive mindreading may be paraphrased as “I know that you know that I know that you know” etc. For successful intentional communication, “the communicator needs some kind of cognitive model of how the recipient perceives the signal and acts as a result” (Tomasello 2010: 45).

As far as the evolutionary and cultural-historical processes underlying the development of human cooperative communication and the differentiation of about 6,000 different conventional languages are concerned, Tomasello’s (2010: 11) proposal “basically turns the Chomskian proposal on its head, as the most fundamental aspects of human communication are seen as biological adaptations for cooperation and social interaction in general, whereas the more purely linguistic, including grammatical, dimensions of language are culturally constructed and passed along by individual linguistic communities.”

This view is, of course, also diametrically opposed to Chomsky’s present position. In a lecture given as an Albertus-Magnus-Professor at the University of Cologne in June 2011, Chomsky claimed that “the question whether language exists is basically whether UG exists.” Such a claim seems immune to refutation.

If it seems impossible at present to refute the UG hypothesis, the question arises whether supporting empirical evidence can be found. This is what generativists have been and are being concerned with. Thus, in example (1), the question is about whether the eagle can swim and not whether it can fly. This type of example goes back to the 1980ies when generativists claimed that “structure dependence is the ‘parade case’ of an innate constraint” (Ambridge & Lieven 2011: 300; see also Chomsky 1980).

- (1) Can the eagle that can fly swim? (from Chomsky 2011)

Most importantly, the argument of structure dependence rests on the hypothesis that “questions are generated by movement” (Ambridge & Lieven 2011: 302). Example (1) is thus taken to be derived from example (2a) by taking its hierarchical rather than its linear structure into consideration. Moving the first occurrence of the modal auxiliary *can* to the front would, of course, result in the ungrammatical structure (2c).

- (2) (a) [The eagle that can fly] can swim.
(b) Can [the eagle that can fly] swim?
(c) *Can the eagle that fly can swim?

As early as in 1980, Chomsky claimed that in spite of the fact that children almost never hear relevant evidence such as example (2b), they do not produce structure-dependence errors (example 2c). He concluded from this that structure dependence must be innate.

As demonstrated by Ambridge & Lieven (2011: 300-302), an innate constraint is unnecessary to explain children’s acquisition of *yes/no* questions containing relative clauses. According to the constructivist account, children can construct *yes/no* questions with an embedded relative clause on the basis of constructional templates or schemas such as (3) in which either a simple NP without a relative clause (e.g. *the eagle*) or a complex NP containing a relative clause (e.g. *the eagle that can fly*) may be inserted into the NP slot.

(3) [MOD.AUX] [NP] [V]

The main difference between the generativist and the constructivist approach to the acquisition of *yes/no* questions is that the first rests on the hypothesis that “questions are generated by movement” while the second does not (Ambridge & Lieven 2011: 302). According to the constructivist account, “utterances that are not complete complex *yes/no* questions can still provide evidence with regard to the form of this structure” (Ambridge & Lieven 2011: 302). Thus, the simple NP *the boy* and the complex NP *the boy who is smoking* share the same distribution since the complex NP can be substituted for the simple one in the slot in (4).¹

(4) _____ is crazy. (from Ambridge & Lieven 2011: 300)

If examples such as this one can be multiplied and no empirical evidence can be found for the UG hypothesis, the latter hypothesis must be abandoned on the account of the scientific principles that the data should “constrain the theory” (Karmiloff & Karmiloff-Smith 2001: 142) or that “a theory should make as few assumptions as are necessary to understand the data” (Ambridge & Lieven 2011: 376).

Tomasello (2010: 313) justifies his proposal of abandoning the UG hypothesis by arguing for the learnability of language from the input and accordingly refutes the generativist poverty-of-the-stimulus argument. The poverty-of-the-stimulus argument claims that there is an infinite number of possible hypotheses which are consistent with the child’s linguistic experience, but are linguistically incorrect, so that categories, rules and principles must be innate (Ambridge & Lieven 2011: 371).

What is the theoretical status of principles, rules, and categories? As mentioned above, in Chomsky’s most recent versions of the UG hypothesis, principles have been reduced to the computational operations of recursion and merge. As pointed out by Tomasello (2010), recursion is not specifically linguistic, but a basic cognitive skill of shared intentionality, namely recursive mindreading. The operation “merge” could eventually be compared to Bybee’s “chunking”, one of a few domain-general, i.e. not specifically linguistic, cognitive processes relevant for studying language. According to Bybee (2010: 7), “chunking is the process by which sequences of units that are used together cohere to form more complex units.”

In the generativist framework, linguistic rules are very general “contentless, algebraic” operations for combining linguistic units (Tomasello 2010: 275). Such symbolic rules describe highly productive morphology on the one hand and syntactic generalizations on the other (Bybee 2010: 64, 73). In the constructivist approach, grammatical knowledge, rather than being innate, is taken to emerge “from the categorization of experienced utterances” (Bybee 2010: 78) resulting in a structured list of constructions, i.e. more or less general patterns of usage.

While the generativist account of language structure stresses generality, the constructivist account points to its gradient character. This difference becomes especially clear in the approach to morphology in both accounts. The generativist approach is forced to assume two distinct processing types, namely analogical processes for ‘irregular’ lexical patterns, but symbolic processing in the rules component of the lexicon for ‘regular’ patterns (see Bybee 2010: 73), whereas the constructivist approach argues “for a gradation between unproductive, specific patterns and the most productive, general patterns” (Bybee 2010: 73).

Constructions reach from most abstract or schematic to most concrete or specific ones and represent the most important category of the constructivist approach (Ambridge & Lieven 2011: 127). Tomasello (2010: 296) defines constructions as “essentially prefabricated, meaning-bearing structures for use in certain recurrent communicative situations.” Bybee (2010: 76) stresses that they are “direct pairings of form with meaning [...], often having schematic positions that range over a number of lexical items.” Constructions are therefore directly or indirectly item-based. They may be quite concrete and consist of particular words or phrases (examples 5a) or they may involve abstract patterns of word types (schema 5b). Schemas such as the one for constructing certain English *yes/no* questions represent generalizations constructed on the basis of a number of exemplars. Finally, constructions may consist of a mixture of constant and variable patterns implemented by a number of concrete exemplars (example 5c).²

¹ According to Dąbrowska & Lieven (2005), hierarchical structure is created by “superimposition”, i.e. by elaborating a schematic slot in a construction (see Bybee 2010: 65).

² See also Ambridge & Lieven (2011: 126).

- (5) (a) *ti kanis?* ‘how are you?’ *xronia pola!* ‘(may you live) many years!’
 (b) [MOD.AUX] [NP] [V]
 Exemplars: *can eagles swim?* *will the boy win?* *must Mary leave?* *should the child who left home return?* etc.
 (c) *thelo na V*
 Exemplars: *thelo na fiyo* ‘I want to leave’, *thelo na kimiθo* ‘I want to sleep’, *thelo na fao* ‘I want to eat’, *thelo na diavaso* ‘I want to read’ etc.

While admitting that patterns for the English auxiliary or the English regular Past Tense formation might suggest abstractions in the form of symbolic rules, Bybee (2010: 103) points out that “the availability of a pattern as a model for the analogical formation of novel exemplars of the pattern can provide a much more concrete explanation for generality without resorting to abstractness.”

The fact that, in the constructivist view, even abstract syntactic patterns are taken to be based on classes of similar exemplars of meaning-bearing constructions rather than on contentless algebraic rules, has immediate consequences for the learnability of syntactic structures. While concrete constructions such as those in (5a) can be learned by imitation, abstract constructions must be reconstructed by the child. According to Tomasello (2010: 298), this means that children must recognize patterns of use “across individual learning experiences with different exemplars of the construction”, i.e. they must be able to categorize linguistic experiences. It has been demonstrated that not only 7- to 8-month-old prelinguistic human infants “are able to find patterns in sequentially presented auditory stimuli” (Tomasello 2003: 28), but that this capacity even extends to nonhuman primates when these are presented with tone sequences or visual sequences (Tomasello 2003: 30). In language acquisition, pattern-finding skills must be used not only on the formal but also on the functional side of linguistic utterances (Tomasello 2003: 30-31).

As pointed out by Bybee (2010: 7), “memory for linguistic forms is represented in exemplars, which are built up from tokens of language experience that are deemed to be identical.” Thus, language learners “map similar tokens onto one another to establish exemplars and these exemplars group together to form categories that represent both the fixed and schematic slots in constructions” (Bybee 2010: 26). Consequently, constructions are “surface based and can emerge from the categorization of experienced utterances” (Bybee 2010: 78).

The emergence of constructions is illustrated in (6). Tokens such as (6a) are classified as exemplars such as (6b) resulting in the concrete constructions (6c) so that, finally, the rather abstract construction (6d) emerges. It is important to note that, in contrast to a generative rule, the schema (6d) is indirectly item-based.

- (6) (a) tokens:
thelo na fiyo, thelo na fiyo, thelo na fiyo, etc.
 ‘I want to leave’
prepi na fiyo, prepi na kimiθo, prepi na fao, prepi na diavaso, etc.
 ‘I must leave/sleep/eat/read’
thelo na kimiθo, thelo na fao, thelo na diavaso, etc.
 ‘I want to sleep/eat/read’
 (b) exemplars:
thelo na fiyo, thelo na kimiθo, thelo na fao, thelo na diavaso
prepi na fiyo, prepi na kimiθo, prepi na fao, prepi na diavaso
 (c) concrete constructions:
thelo/prepi na fiyo/kimiθo/fao/diavaso
 (d) more abstract construction:
 MOD.V na V

It has been found that, in the acquisition of constructions, children do indeed start out from very specific points storing experienced exemplars and gradually expanding on these to arrive at more general patterns.³ As pointed out by Bybee (2010: 78), the acquisition process thus consists in the children’s “process of formulating partially schematic constructions on the basis of the specific utterances they have mastered and can use” (Bybee 2010: 78).

³ Tomasello (1992; 2003), Lieven et al. (1997), Dąbrowska & Lieven (2005).

In the usage-based or constructivist model of language, relations between linguistic forms can be formed on various levels, such as the word, phrase or sentence level (Bybee 2010: 22). As far as morphological relations on the word-level are concerned, these “are emergent from relations formed among words due to their semantic and phonetic similarity” (Bybee 2010: 22). Examples (7) and (8) illustrate such morphological relations from Greek verbal and nominal inflection.

- (7) ayorasa PAST:PFV:1S ‘I bought/heard/read/wrote/painted’
 akusa PAST:PFV:1S
 diavasa PAST:PFV:1S
 eyrapsa PAST:PFV:1S
 zoyrafisa PAST:PFV:1S
- (8) anθropos NOM:SG ‘human being/president/Spiros/teacher/list’
 proeδros NOM:SG
 Spiros NOM:SG
 δaskalos NOM:SG
 kataloyos NOM:SG

In both sets of examples, the underlined parts of the forms as well as their grammatical functions are identical so that these word forms become related in a common morphological pattern or schema.

In contrast to the structuralist (and generativist) analytical approach, which considers complex morphological forms to be constructed from a base with units added to the base by a symbolic rule such as (9), the usage-based approach is goal-directed and considers complex forms as wholes or *gestalts* whose internal structure is discovered by relating them to similar morphological forms with similar grammatical function in the language. Packages of such similar form-function pairs constitute schemas and guarantee productivity.

- (9) Engl. $V+ed \rightarrow V_{past}$

As pointed out by Bybee (2010: 23) “one advantage of this approach to morphological analysis is that it does not require that a word be exhaustively analyzed into morphemes.” This especially applies to the description of fusional languages such as Greek where the segmentation of forms may lead to problems. As noted by Matthews (1991), the question whether a form such as *anθropos* should be segmented as in (10a) or (10b) depends on the forms with which it is compared.

- (10) (a) *anθrop-os* vs. *anθrop-u/anθrop-i/anθrop-e*
 (b) *anθropo-s* vs. *anθropo-Ø/anθropo-n*

In a morphologically rich language like Modern Greek, a given inflectional form can enter into several networks of associations as exemplified by examples (11a) and (11b). As will be shown in section 4, the simultaneous membership of forms in the network of nouns ending in *-os* and in that of nouns ending in *-Vs* may lead to a wrong classification of nouns in Greek child language acquisition.

 kataloyos NOM:SG kafes NOM:SG

In order to be able to refute the hypotheses of the generativist or the constructivist approach considerable further work is needed. Ambridge & Lieven (2011: 374) note that if the constructivist account is to be falsifiable, “the processes by which a child moves from more lexically specific to fully abstract constructions” must be addressed in more detail (but see Tomasello 2003). Another issue which must be dealt with is “how children learn to integrate knowledge from different constructions” (Ambridge & Lieven 2011: 374).

Before discussing empirical evidence for the acquisition of Greek nominal and verbal inflection, the two major current theoretical models of the acquisition of inflectional morphology must be considered.

3. The single-route vs. double-route processing model of the acquisition of inflection

While constructivists propose a single-route processing model of the acquisition of inflection, the dual-route model is defended by generativists. As mentioned above, the generativist approach assumes two distinct morphological processing types, analogical processes for ‘irregular’ patterns and symbolic rules for ‘regular’ ones (Bybee 2010: 73). In contrast to this, in the constructivist approach it is accepted that analogical processing also constitutes the basis for creating novel utterances. Productivity is therefore accounted for by analogy rather than by the application of rules (Bybee 2010: 75). Accordingly, constructivists assume that analogy, which operates across stored exemplars of inflected forms (Ambridge & Lieven 2011: 169), is sufficient to account for the acquisition and processing of regular as well as irregular inflection.

The most important difference between the inflectional schemas of the constructivist approach and the general inflectional rules of the generativist theory is that schemas are organizational patterns of categorized items, while symbolic rules act on variables such as Noun or Verb and “are postulated to exist independently of the forms to which they apply” (Ambridge & Lieven 2011: 169; see also Tomasello 2003: 237). Thus, the ideal inflectional rule is a general, ‘default’ rule applying to any member of a given part of speech, with the exception of irregular forms (Ambridge & Lieven 2011: 169). In contrast, inflectional schemas “have no existence independent of the lexical units from which they emerge” (Bybee 2010: 74).

Positing a strict division between regular and irregular inflectional processes poses a major empirical problem for linguistic typology since there are languages like Modern Greek which possess several inflectional patterns in nominal as well as verbal morphology, all reaching from more productive to less productive or even exceptional. Such languages are more adequately described by a continuum of gradient productivity than by a sharp division between productive, ‘regular’ and unproductive, ‘irregular’ forms.

The two theoretical conceptions of inflectional morphology also lead to important differences in their account of acquisition. According to the generative dual-route model, irregular forms, such as the English past tense forms *went*, *saw*, *threw*, are stored in memory in pairs with their stem forms (examples 12a), whereas regular past tense forms, such as *played*, *walked*, *hinted*, are generated by the regular past tense formation rule in (12b).

- (12) (a) *go/went, see/saw, throw/threw*, etc.
(b) *play, walk, hint*, etc.

$$V + ed \rightarrow V_{\text{PAST}}$$

played, walked, hinted, etc.

Regular and irregular inflectional forms are thus taken to be produced by different mechanisms or via different routes (Ambridge & Lieven 2011: 170), namely retrieval from memory and generation by rule, respectively. Generativists assume the distinction between the lexicon, in which words are stored, and the grammar, in which rules operate, to be innate (Ambridge & Lieven 2011: 170). Accordingly, the regular-route mechanism is also taken to be innate. As pointed out by Ambridge & Lieven (2011: 170), this leads to the most problematic assumption that this mechanism “lies dormant for morphological systems and languages that do not have a regular system,” a hypothesis which is theory-driven and cannot in principle be tested empirically.

By contrast, the constructivist single-route model does not assume innate grammatical categories or a lexicon vs. grammar division. Regular as well as irregular forms are taken to be stored in memory and the main force organizing the associate network of grammatical forms is formal and semantic analogy. There is thus no default rule and also “no need for an extra set of blocking mechanisms to keep these abstract rules from applying too widely” (Tomasello 2003: 239). Rather, English past tense formation depends on memory storage and, in case of rare verbs, on input frequency and the corresponding availability of schemas (Ambridge & Lieven 2011: 171).

Although the constructivist schema in (13) may at first glance look similar to the generative rule in (12b), there are two important differences: 1. The rule in (12b) is postulated to exist independently of the forms to which it applies, while the schema (13) remains tied to concrete inflectional forms such as those given in (14) from which it has emerged in language acquisition. 2. The rule in (12b) is source-directed and generates regular English Past forms by adding the suffix *-ed* to the verb stem, while the

schema (13) is goal-directed and describes the form and function of regular Past Tense forms of English verbs.

(13) [[VERB] d] Past Tense (from Bybee 2001: 22)

(14) English regular past forms (from Bybee 2010: 23)

pleid	PAST
spild	PAST
spɔild	PAST
bænd	PAST
ræmd	PAST

While, in the constructivist approach, type and token frequency of inflectional forms play a dominant role in acquisition, in the generativist approach, they do not (Tomasello 2003: 238). Type and token frequency are important for productivity and entrenchment, respectively. The productivity of a schema is a function of “its type frequency in terms of the number of different lexemes with which it has been used” (Tomasello 2003: 238). The more often a given form is experienced or used the more firmly it will be established or “entrenched” in memory. In the generative approach, only the acquisition of irregulars is sensitive to input frequency and phonological and semantic similarity (Tomasello 2003: 238).

Since the single-processing model “can handle the same range of data that is handled in the dual-processing model by two mechanisms” Bybee (2010: 74) puts “the burden of proof” on “those who propose two processing mechanisms rather than one.” Adopting her point of view, I will therefore content myself with presenting evidence for the single-route model in the acquisition of Greek nominal and verbal inflection.

4. Evidence for the single-route model in the acquisition of Greek nominal and verbal inflection

The empirical evidence used for exemplifying the acquisition of Greek morphology comes from the naturally occurring speech of six monolingual Greek children observed between the last part of their second and the last part of their third year or beyond. The data are found in the computerized part of the Corpus Stephany (3 girls, 1 boy) entered in the CHILDES Data Base (CHILDES Project, Carnegie Mellon University, Pittsburgh, NJ, USA, directed by Brian MacWhinney) and in the corpora gathered by Anastasia Christofidou (boy Christos) and by Demetra Katis (girl Anna).

As mentioned above, a two-fold distinction between fully productive ‘regular’ and unproductive ‘irregular’ inflectional structure is inappropriate for the description of Modern Greek inflectional morphology, where several inflectional patterns exhibiting gradient productivity compete in each of the major parts of speech. Furthermore, it is unlikely that children faced with the acquisition of such a rich and complex inflectional system could possibly be able to ‘link’ hypothesized innate lexical default rules to any set of inflected forms. Rather, they will try to come to grips with experienced inflectional items by storing both their form and meaning in memory and gradually systematizing them by grouping formally and semantically similar ones. In this way, morphological development will start from specific lexical items proceeding to item-bound patterns and finally to more abstract schemas comprising larger sets of items.

Detailed analyses of observational data of Greek language acquisition have shown that the categories of Greek inflection and derivation develop piecemeal rather than across-the-board (Stephany 1985, 1997; Stephany & Christofidou 2009; Christofidou & Stephany 2003; Thomadaki & Stephany 2007). No evidence for general rules concerning plural or case formation in the noun or the inflectional categories of mood, aspect, tense, voice, person and number in the verb has been found.

The most important result in the morphologically less rich domain of Greek noun inflection is that number and case distinctions do not develop in unison and across-the-board for all nouns. Thus, in Mairi’s speech from 1;9 to 2;9, number and case develop separately within certain gender classes (Fig. 1). While number distinctions first emerge and develop in neuter nouns, the first case distinction is limited to masculine nouns. A similar pattern is found with Christos (Stephany & Christofidou 2009). There is thus neither a general number nor a general case contrast to be found in the early speech of the two children studied by Stephany & Christofidou (2009). The authors conclude that as long as children only oppose singular and plural forms of neuter nouns, but not of masculine ones, “we do not have

evidence to affirm that they have generalized the number contrast to all nouns” (Stephany & Christofidou 2009: 256). A similar conclusion holds for case distinctions.

Figure 1 Inflectional development of the Greek noun
(from Stephany & Christofidou 2009: 230)

The inflectional development of diminutives carrying the three most frequently used suffixes *-aki*, *-ula* or *-itsa* in the extensive corpus of Anna’s speech between 1;8 and 3;0 supports the above findings. Tracing the inflectional development of these diminutives Thomadaki & Stephany (2007: 110-112) found that number distinctions emerge before case distinctions and are at first limited to neuter diminutives ending in *-aki*. Within this class of diminutives, the development of number distinctions is item-based. While the noun *peḍaki* ‘child:DIM’ is used in both the singular and plural at 1;8 when it first appears, seven other diminutives ending in *-aki* first emerge in either their singular or plural form and are found in the other number only one to five months later. Since, in Standard Greek, the genitive is not used with diminutives ending in *-aki* (Thomadaki 2008), no case distinction develops in this class of diminutives.

The development of number and case distinctions proceeds differently in the two classes of feminine diminutives ending in *-ula* and *-itsa*. While the unmarked nominative-accusative singular form of diminutives ending in *-ula* is contrasted with both the marked genitive singular and the nominative-accusative plural already by 1;11, the first genitive singular forms of diminutives ending in *-itsa* only occur at 2;9 (Thomadaki & Stephany 2007: 111, table 9).

Further evidence for the development of nominal inflection as “a gradual process of spreading systematicity” (Stephany 1997: 324) comes from the analysis of the early fine-grained observational data of the boy Christos (Stephany & Christofidou 2009). Marked nominative singular forms of masculine nouns ending in *-s* are restricted to certain animate masculine nouns when they first appear shortly before the turn to the second year. Use of these marked forms is subsequently extended to nouns referring to male beings more generally and finally, two months after their first appearance, to inanimate masculine nouns. The overextension **Plutos*, which is found less than two weeks after the first occurrence of a marked masculine, cannot be taken as evidence for the development of a general nominative marking rule for masculine nouns since more general marking of this noun class still has to wait for at least another six weeks. Rather, the non-standard form **Plutos* must be explained as an analogy to form pairs such as *Christos/Christo* ‘Christos’ or *papus/papu* ‘grandfather’.

Our data also give evidence of the role of personal linguistic experience in inflectional development. Different linguistic experience can explain the variation in the development of nominative-singular marking of masculine nouns of the boys Christos and Spiros compared with the girl Mairi. While the boys rely more strongly on synthetic marking, Mairi in many cases combines the nominative form of the definite article with the unmarked form of the noun. This difference can be attributed to the fact that both Christos and Spiros, but not Mairi, must have experienced many examples of the nominative-accusative contrast of their respective first names belonging to the class of masculine nouns (*o Christos/Spiros* vs. *ton Christo/Spiro* but *i Mairi* vs. *ti Mairi*) (Stephany & Christofidou 2009: 240).

There is evidence for early pattern formation in Christos’ data not only in the overgeneralization of the *-s* marker, but also in the way the boy handles the *dhiptota* and *triptota* subclasses of masculine nouns distinguishing two versus three singular case forms. In contrast to the other children studied by Stephany (1997) and Stephany and Christofidou (2009: 246), Christos at first generalizes the *dhiptota*

pattern to all masculine nouns by constructing a single inflectional pattern for all of them. It contains a simple contrast between the marked nominative singular and an unmarked oblique case form covering the accusative as well as the genitive singular of Standard Greek. In his early speech, Christos thus seems to have based pattern formation on examples such as the marked nominative singular forms given in (15a) contrasted with the unmarked oblique forms in (15b). It is only by 2;3.18 that Christos starts to distinguish between two declensional subclasses of masculine nouns by marking animate nouns ending in *-os* by *-u* in the genitive singular (Stephany & Christofidou 2009: 246).

- (15) (a) Christos NOM:SG (b) Christo *OBL:SG
 adras NOM:SG adra OBL:SG
 papu NOM:SG papu OBL:SG
 kaθijiti NOM:SG kaθijiti OBL:SG
 kafes NOM:SG kafe OBL:SG

The fact that inflectional development is gradual rather than a matter of all or nothing is also substantiated by the observation that it may proceed at a different pace in distinct inflectional categories. This may concern onset and speed of verb inflection as compared to noun inflection. Thus, in the data of one girl at 1;11, only 1% of noun tokens occur in an inflectionally marked form such as the plural (Stephany & Christofidou 2009: 254) while, at the same age, she already distinguishes between three moods, two aspects, two tenses and both the first and third person singular and plural of the verb (Stephany & Christofidou 2009: 255; see also Stephany 1985 and 1997).

Due to the rich inflectional morphology of the Greek verb, it is to be expected that massive evidence for the piecemeal character of the emergence of inflectional categories will be found in the development of this grammatical category. A detailed study of verb forms used by Christos at 1;11 and 2;0 shows the lexeme-bound development of the categories of tense, aspect, and mood as well as person and number (Table 1).

Verbs	Inflectional categories							
	IPFV: NONPAST: 3S	IPFV: NONPAST: 3P	IPFV: NONPAST: 1S	PFV: PAST: 3S	PFV: PAST: 3P	PFV: SUBJ: 3S	PFV: SUBJ: 1P	IMP: 2S

<i>pezo</i> 'play'		✓					✓	
<i>kaθome</i> 'sit'						✓		✓
<i>pefto</i> 'fall'				✓	✓			

Table 1 Christos' verb forms at 1;11 and 2;0 (adapted from Christofidou & Stephany 2003:119)

In each of these two months, five verbs are used in two forms each. In spite of the fact that three specific combinations of grammatical categories occur with two or even three different verbs, the specific contrasts of forms documented in the boy's speech differ from verb to verb. Although it might be argued that this picture is partially due to lack of data, it would seem presumptuous to claim that the child has generally mastered all of the grammatical categories documented by a single verb or at most three of them. On the other hand, Table (1) clearly shows that verbal inflection has begun to develop since, at 1;11, the boy uses six of his 20 verbs in at least two different forms serving different functions. The same holds for the 23 verbs occurring a month later.

A comparison of Christos' and Mairi's development of verbal inflection towards the end of their second year shows that there may be quite important individual variation in inflectional development. At 1;9, Mairi uses 64 verbs, nearly three times as many as Christos. More than half of these occur in two to seven functionally distinguished forms (Christofidou & Stephany 2003: 110). In spite of this, the productivity of given bundles of inflectional categories varies considerably. Thus, in the imperfective non-past ('present'), the third person singular is used with 19 different verbs while the first person occurs with merely 8 verbs. In the perfective subjunctive, on the other hand, the relation between third and first person singular is reversed: the first person is used with 14 verbs, but the third person with only 5. The first person plural points in the same direction: While it is used with 12 different verbs in the perfective subjunctive, it only occurs with 2 verbs in the imperfective non-past. At this point in development, Mairi accordingly overextends the third person singular to refer to the speaker much more frequently in the indicative than in the subjunctive, in which the first person is more firmly established (Christofidou & Stephany 2003: 107). Person-number categories thus develop differently in

different tense-aspect-mood categories. This is more evidence for their piecemeal (although not necessarily unsystematic) inflectional acquisition.

The same kind of evidence is found in the development of aspect and tense in Greek child language acquisition. Rather than being documented with all or at least most verbs occurring in the children's speech, specific combinations of aspect and tense depend on input frequency as well as the aspectual character or *aktionsart* of verbs (see Stephany 1985, 1997; Christofidou & Stephany 2003: 118). Thus, durative, atelic verbs such as *pezo* 'to play' or *diavazo* 'to read' are most likely to be used in the imperfective non-past, while punctual, telic verbs like *pefto* 'to fall' or *xalao* 'to break' most frequently occur in the perfective subjunctive or the perfective past (Stephany 1985: 116-117).

The kind of evidence which is usually considered to be most convincing for children's systematic or rule-like linguistic behavior are systematic errors such as the overgeneralization of inflectional patterns. This has even led some psycholinguistics to postulating a stage of overgeneralization or regularization in the acquisition of English (Ervin 1964). As far as the inflectional characteristics of early child Greek until the age of 3;0 or even 4;6 are concerned, there is no evidence for U-shaped learning, let alone a stage of overgeneralization or regularization (Stephany 1989; 1997: 323-324). The relatively few overgeneralizations which do occur are based on several inflectional models rather than a single one (Stephany 1997: 324) and are therefore better explained by analogy than general rules.

A few examples of form shift from rarer to more common inflectional patterns are found with both nouns and verbs. Rare neuter nouns ending in *-os* such as *to dasos* 'the wood' in (16a) may be reinterpreted as belonging to the common neuter class ending in *-o* so that their plural is formed according to the *-o/-a* pattern resulting in non-standard *ta *dasa* instead of *ta dasi* in a child's spontaneous speech at 4;6 (Stephany 1997: 222). At 2;5, another girl interprets the form *maimu* 'monkey' in (16b) as the oblique singular of a masculine noun in analogy to nouns such as *papus/papu* 'grandfather' and forms the non-standard nominative **maimus* on this basis (Stephany 1997: 223).

- (16) (a) 4;6 *to dasos* 'the wood' → *ta *dasa* instead of *ta dasi* 'the woods'
 (b) 2;5 *maimu* 'monkey:OBL:SG' → **o maimus* NOM:SG for *i maimu*

Overgeneralization errors in verbal inflection are sometimes based on the more frequent verb stem. Due to "children's extensive use of the subjunctive mood to express deontic meanings, perfective stems of dynamic verbs (especially telic ones) are more frequent and accordingly better known than imperfective ones" (Stephany 1997: 246). This may lead to an analogical derivation of imperfective stems from perfective ones or even to a shift of verbs from the less common second conjugation to the more common first conjugation. An example is the non-standard imperfective non-past form **xaládis* 'you break' for standard *xalás* found in the spontaneous data of a child at 2;3 (example 17). The child's form **xaládis* is based on the frequently occurring perfective subjunctive *xalásis* in *tha xalásis* (FUT.PTL break:PFV:NONPAST:2S) 'you will break' or *na min xalásis* (MOD.PTL MOD.NEG break:PFV:NONPAST:2S) 'you must not break' so that the pair **xaládis/xalásis* represents an analogy to first conjugation form pairs such as *diavazis/diavasis* 'you read:IPFV/PFV:NONPAST:2S' or *zoğrafizis/zoğrafisis* 'you paint:IPFV/PFV:NONPAST:2S' and many others.

- (17) 2;3 **xaládis* for *xalás* (break:IPFV:NONPAST:2S) 'you break'

With the exception of the overuse of certain person-number forms such as the third person singular in reference to the speaker and sometimes even the hearer, overgeneralization errors of verb endings are very rarely found in Stephany's (1985) data of five children until the end of their third year and Katis' (1984) extensive data of children until the end of their fourth year (see also Stephany 1997). All of these can be explained by analogy to more frequent patterns. One of the errors found is the regularization of the irregular form *lene* 'they say' to **lenun* at 2;11 (example 18) in analogy to regular first conjugation verb forms such as *peftun* 'they fall' or *diavazun* 'they read' (Stephany 1997: 251).

- (18) 2;11 **lenun* instead of *lene* 'they say'

In her summary of the inflectional development of Greek child language acquisition until the end of their third or fourth year, Stephany (1997: 323) states that what is most characteristic of Greek children's speech is underdifferentiation of forms and a corresponding overgeneralization of functions rather than incorrect inflectional forms. Examples are overuse of the unmarked singular forms of nouns in contexts where marked case forms occur in Standard Greek or the referential overuse of the third person of the verb mentioned above. Furthermore, due to missing or at least unreliable particle use, the subjunctive mood and the strongly modalized future tense are often merged in early child Greek.

Aspect and tense are also merged, since imperfective indicative forms are typically non-past and perfective ones past (Stephany 1985). After the emergence of marked grammatical forms of nouns “the old forms of nouns ending in the thematic vowel, which are underdifferentiated for case in the child’s system (Stephany 1997[...]: 323), will specialize to fulfill the functions of a specific case form (accusative or oblique) thereby developing into grammatical forms of the adult language (see also Katis 1984; Stephany 1985, 1992)” (Stephany & Christofidou 2009: 256).

It follows from these observations that grammatical development is emergent in Greek language acquisition (Stephany 1992) and, as mentioned above, consists in “a gradual process of spreading systematicity” (Stephany 1997: 324) so that “expression of inflectional categories develops locally” rather than across-the-board (Stephany 1997: 324). Thus, a certain category is at first distinguished with certain stems and stem types and not yet with others. “Since children are more exposed to certain forms of certain types and will also use them more often than others, their experience with inflectional forms will not grow at an equal pace with all forms and stem types” (Stephany 1997: 324). “Over the course of time, grammatical distinctions are generalized and spread out within specific subclasses of lexemes following the same inflectional pattern and beyond. In this view, children are considered to gradually construct the inflectional system of their language, based on the way they hear their caretakers use it” (Stephany & Christofidou 2009: 256-257).

In summary, what has been found in the early development of Greek verbal and nominal inflection is massive evidence for stored exemplars of specific forms expressing bundles of grammatical categories rather than evidence for general symbolic rules. Accordingly, there is no evidence for the dual process model of inflectional acquisition. In addition, large evidence for analogy, let alone general default rules, would predict a great amount of inflectional errors, something which is not found in spontaneous early Greek child data. Interpreted in the framework of the constructivist, usage-based approach to language acquisition, early inflectional development of Greek children shows that their linguistic skills are much less abstract than generativists are likely to assume.

5. Conclusion

In trying to answer the question of how to select a theoretical framework for one’s own empirical linguistic research, it must be pointed out that, to a considerable extent, such a selection depends on what one has been taught during academic education as well as on the advances in the particular academic field. This may lead to a change in one’s theoretical convictions in the course of time.

Thus, my linguistic education in the United States of America including a summer during which I studied phonology and syntax with Chomsky, led me to choose his *Aspects of the Theory of Syntax* model (Chomsky 1965) as a theoretical framework for my doctoral dissertation on the French attributive adjective (Stephany 1970). Because of my ensuing dissatisfaction with the formal and abstract generativist approach to language and its rapidly changing grammatical models, I adopted a cognitively based theoretical framework for my postdoctoral thesis on the development of verbal grammar in Greek first language acquisition (Stephany 1985). Although, several years ago, this study was dismissed as “traditional” by a fervent young generativist, in the meantime, the cognitivist, usage-based approach to language acquisition has proved to perfectly fit its empirical results and also those of further work on Greek language acquisition (e.g. Stephany 1997). In my opinion, there are two reasons for preferring the usage-based approach to the generativist one: (1) it seems more apt to explain what is going on in the process of language acquisition and (2) its adult endpoint, namely the linguistic knowledge of mature speakers, is more realistic. If “the adult endpoint of language acquisition comprises nothing other than a structured inventory of linguistic constructions”, the target of language acquisition is much more child-friendly than believed by generativists (Tomasello 2003: 7) and can be attained without assuming an inborn Universal Grammar.

ABSTRACT

In Tsimpli and Dimitrakopoulou's (2007) Interpretability Hypothesis (IH), postpubertal L2ers cannot acquire LF-uninterpretable features nonexistent in the L1; no problem is anticipated regarding LF-interpretable features. We tested the IH with Greek definite and indefinite articles in the interlanguage of L1 Slavic, English and Romance adults who had received massive exposure to Greek. Oral data obtained from a picture description and a sentence repetition task offer only partial support to the IH: learners were nonnativelike only in some uses of the definite article where LF-uninterpretable features are involved; moreover they fared better at the definite than at the indefinite article, despite that the latter bears only LF-interpretable features. There were also L1 effects and task effects.

Keywords: Adult L2 Greek, definite/indefinite articles, features, interpretability hypothesis

1. Introduction: General Background to the Study

This study investigates articles in Greek as a second language (L2) acquired at adulthood, within the Universal Grammar (UG) framework of the Minimalist Program (Chomsky 1995). In this framework lexical items in the language faculty consist of bundles of abstract features, such as number, case, gender, animacy etc. Crucially for the present study, some of these features have semantic content and are thus interpretable at the Logical Form (LF), which is the interface between the Computational System and the Conceptual-Intentional System. Other features, however, are not interpretable at LF as they merely serve grammatical operations. For example, the feature [number] is LF-interpretable when it is morphologically realized on nouns, yet it is LF-uninterpretable when it is marked on items of functional categories such as determiners or adjectives; in the latter case the respective morphological marking reflects grammatical agreement between the noun, the determiner and the adjective and is interpretable only at the phonetic form (PF), that is the interface between the Computational System and the Articulatory-Perceptual System. Also, features such as [+/-animacy] marked on pronouns (e.g. he/she/it) or [+/-definiteness] marked on determiners (e.g. a, the) in English, are LF-interpretable.

It is well known that postpubertal learners rarely reach nativelike proficiency, despite massive exposure to L2 input (e.g. Johnson and Newport 1989; DeKeyser 2000). This is often manifested as persistent selective divergence from native grammars (Franceschina 2005). An account offered for this phenomenon is Tsimpli and Dimitrakopoulou's (2007) Interpretability Hypothesis¹ (hereafter IH) suggesting that postpubertal language learners have access to UG principles and LF-interpretable features but lack access to LF-uninterpretable features lacking from the learners' L1². Put differently,

¹ For an earlier formulation of this hypothesis see Tsimpli and Roussou (1991).

² Besides L2 acquisition, the IH has been employed to account for phenomena in L1 acquisition, L1 attrition and Specific Language Impairment (see Tsimpli and Mastropavlou 2007 and references therein).

features related with parameterization are subject to a critical age period (see Lenneberg 1967) and resist resetting (Tsimpli and Dimitrakopoulou op. cit.: 224)³. Also, according to the IH, learners may employ LF-interpretable features to compensate for LF-uninterpretable ones (if the latter lack from their L1) in the acquisition of certain structures. This may result in successful performance but the learners' mental representation of the specific structures is still non-nativelike (and possibly unlike the mental representation of any L1 structure too)⁴.

Other hypotheses, however, propose that there is access both to UG principles as well as to both LF-interpretable and LF-uninterpretable features⁵ in postpuberty (Schwartz and Sprouse 1996) and persistent divergence from the L2 norms may relate to processing problems (Prévost and White 2000) or deficient knowledge of L2 morphology (Lardiere 1998).

Greek articles provide a good testing ground for the IH as we show in the next sections. In the rest of the paper, Section 2 describes the Greek article system and Section 3 overviews previous research on L2 Greek articles and Section 4 outlines our research questions and predictions. In Section 5 we attempt to interpret our results and discuss their theoretical implications. In this final section we also refer to possible limitations of our study and suggestions for future research.

Greek articles provide a good testing ground for the IH as we show in the next sections. In the rest of the paper, Section 2 describes the Greek article system, Section 3 overviews previous research on L2 Greek articles and Section 4 presents the current study. Last in Section 5 we attempt to interpret our results and discuss their theoretical implications. In this final section we also refer to possible limitations of our study and suggestions for future research.

2. Greek Articles⁶

In Greek there is an indefinite and a definite article and both inflect for gender and case; only the definite article inflects for number too. This is shown in Table 1.

INDEFINITE						
	MASCULINE		FEMININE		NEUTER	
	SINGULAR	PLURAL	SINGULAR	PLURAL	SINGULAR	PLURAL
Nominative	enas	Ø	mia	Ø	ena	Ø
Genitive	enos	Ø	mias	Ø	enos	Ø
Accusative	enan	Ø	mia	Ø	ena	Ø
DEFINITE						
Nominative	o	i	i	i	to	ta
Genitive	tu	ton	tis	ton	tu	ton
Accusative	ton	tus	tin	tis	to	ta

Table 1 Greek articles

Given that in Greek there is overt morphological agreement between all members of a Determiner Phrase, both article types carry uninterpretable features such as case, gender and number⁷. The indefinite article always bears interpretable features too. In (1) both the overt indefinite article *ena* and the zero article Ø are [-definite, -specific] while in (2) the indefinite article *mia* is [-definite, +specific].

- (1) *θelo ena sandwich ke Ø biskota*
want-1SG a sandwich and biscuits
'I want a sandwich and biscuits.'
- (2) *iða mia orea kopela*
saw-1SG a beautiful girl.
'I saw a beautiful girl.'

³ A similar view is expressed by the Failed Functional Features Hypothesis (Hawkins and Chan 2007).

⁴ Although this is an important part of the IH, it will not be addressed here.

⁵ For reasons of brevity, in the rest of the paper these features are referred to as just 'interpretable' and 'uninterpretable'.

⁶ This presentation is limited to uses of the Greek articles that relate with our study. The same holds for the description of the learners' L1 article systems (or lack of them) in Section 5.1.

⁷ Except the plural indefinite article, since it lacks morphological realization.

The definite article may also carry the interpretable features [+definite, +specific] as in (3). However, as Tsimpli and Stavrakaki (1999) point out, this article type is also obligatory with proper names, demonstrative pronouns, plural generic nouns in subject position, and complement clauses, as exemplified by (3)-(7), respectively.

- (3) *diavazo *(to) vivlio pu aghorasa hthes*
read-1SG the book that bought-1SG yesterday
'I'm reading the book I bought yesterday.'
- (4) **(i) Zoi efiye*
the Zoi left
'Zoi left.'
- (5) *aftos *(o) andras*
this the man
'This man'
- (6) **(Ta) liontarja ine epikindina zoa*
the lions are dangerous animals
Lions are dangerous animals.
- (7) *den ipe tipota ja *(to) pu tha pame.*
not said-3SG nothing for the where will go-we
'He didn't say anything about where we will go.'

Tsimpli and Stavrakaki (1999) suggest that in contexts like (3)-(7) the Greek definite carries only uninterpretable case, number and gender agreement features without conveying definiteness (or specificity) to its complement.

Last, in object position both massive and singular count nouns can be complements of a zero article in Greek (8).

- (8) *Kaθe proi pino kafe ke diavazo efimerida*
every morning drink-1SG coffee and read-1SG newspaper
'Every morning I drink coffee and read a newspaper.'

3. Previous Research Testing the Interpretability Hypothesis with L2 Greek Articles

The first study on L2 Greek articles that interests us here⁸ is the one by Tsimpli (2003) where the data came from oral interviews with six bilingual speakers of Turkish and Russian. The latter language lacks articles, while in Turkish there is arguably an indefinite article⁹ but not definite ones. The participants in Tsimpli's study had immigrated to Greece at adulthood eight or nine years before the time of the study and had had no prior exposure to Greek. Also, they had all learned Greek without instruction. Results from this study showed that all participants correctly supplied the definite article significantly less (total score: 49%, range: 10%-78%) than the indefinite one (total score: 95%, range: 85%-100%) and half of the participants exhibited ceiling performance on the indefinite article. Given that only the definite article has uninterpretable features, these results were taken as confirmation of the IH. In a subsequent study, Tsimpli and Mastropavlou (2007) compared the data from adults in Tsimpli (2003) against Mavridou's (2003) data from Turkish children. The children had been first exposed to Greek at the age of six years when they started attending a minority primary school in Greece where courses are half in Greek and half in Turkish. The data had been obtained through oral picture-based descriptions. The results showed that those of the children with six years of exposure to Greek performed better than the adults in Tsimpli's (2003) study, and were not significantly worse at the

⁸ Most of the studies discussed in this section also investigated properties of other elements, such as clitics or grammatical agreement between members of determiner phrases. However here we limit the discussion to findings pertaining only to articles.

⁹ There is no agreement as to whether the Turkish word *bir* (=one) is an indefinite article or a numeral. For references see, e.g., Goad and White (2009: 209, fn 1).

definite than at the indefinite article (total scores: 89% and 96% respectively). The discrepancy between the adult and the child data may further corroborate the IH, as it attests to critical period effects on the acquisition of parameterized uninterpretable features.

Dimitrakopoulou, Kalaintzidou, Roussou and Tsimpli (2004) investigated definite articles in data from oral interviews with twenty L2 Greek participants. Each of the participants spoke one, two or three of articleless languages such as Russian, Serbo/Croatian, Turkish and Georgian and had lived in Greece from three to ten years. Again all participants had acquired Greek without instruction. The analysis of results also took into account (a) the participants' age of first exposure to Greek and (b) length of exposure to the language. As found, both of these factors significantly affected the results: those who had arrived in Greece between the ages of nineteen and twenty-three and had been exposed to Greek for ten or more years had the best performance on definite articles (95%). On the other hand, those who had arrived in Greece at a later age (24+) and had resided there for only three or four years had the worst performance (54,6%). Therefore it seems that given enough input, uninterpretable features *are* learnable beyond puberty. Let us point out then that these results seem problematic for the IH as they attest to age effects rather than critical period effects.

Chondrogianni (2008) too probed the validity of the IH with respect to the L2 Greek definite article. The participants were L1 Turkish adults and children residing in Greece. The adults were between nineteen and forty-five years old and had been first exposed to the Greek when they immigrated to the country at ages ranging from twelve to thirty-three years. The children were seven to twelve years old and had had their first contact with the Greek language at kindergarden or primary school, that is when they were five or six years old. Importantly, as time of exposure to a language does not equal size or quality of input, Chondrogianni assessed the participants' level of proficiency in Greek through an independent oral test. The main results, elicited from an oral picture-description test, revealed that child and adult learners with 'high' proficiency in Greek were both very successful in producing the definite article (99.5% and 96.3% respectively) and that the difference between these two groups was not statistically significant. Differences between the two age groups were found only at intermediate levels of Greek proficiency, in favour of the children. This indicates that at some stages of L2 development language acquisition may occur at a faster rate for children but ultimately adult L2 acquirers can catch up. As stated before, Chondrogianni's results apparently disprove the IH as they point to lack of critical period effects on parameterized uninterpretable features.

The take-home point from the above literature review is that results from research on L2 Greek articles are inconclusive as to whether adults can fully acquire uninterpretable features lacking from their L1, which raises doubts about the IH. Therefore the present study aims to further investigate the issue at hand.

4. Research Questions and Predictions

In view of the results from studies previously discussed, our

The main research question was this:

- Given massive exposure to an L2, can postpubertal learners acquire LF-uninterpretable features lacking from their L1?

We predicted the following.

- If the interpretability hypothesis was correct, we expected
 - (a) full mastery of the indefinite but not of the definite article,
 - (b) more problems with the expletive than with the non-expletive uses of the definite article and
 - (c) possible L1 effect, in that speakers of L1s with articles *and* expletive uses of the definite article would fare better than those whose L1 has no expletive articles and even better than those from an articleless L1.
- If, on the other hand, one or more of the above do not occur, there is reason to dispute the IH.

5. The present study

In this section, first we describe the participants, then our tasks and finally we present the results.

5.1 The participants

The participants were 18 adult L2 Greek speakers with an age of first exposure to Greek that ranged from 20 to 38. They had all lived in Greece for a considerable amount of time (minimum: 18 years, maximum: 40 years); 12 of them had completed tertiary education and 6 secondary education. Moreover, about half of them had also received formal instruction in Greek, while the rest had learned the language naturalistically. The participants were separated into three groups according to their L1: Slavic, Germanic and Romance. More details are given in Table2.

GROUPS	NUMBER & L1	YEARS IN GREECE	AGE AT TIME OF TESTING
Slavic	4 Russian, 2 Czech	20.7 (18-30)	46.6 (38-62)
English	6	30.3 (26-40)	56.8 (46-60)
Romance	4 Italian, 2 French	26 (18-33)	55.5 (42-65)

Table 2 Information about the participants

The Slavic group included L1 speakers of Russian or Czech. Like all Slavic languages Russian and Czech lack indefinite or definite articles. In these two languages disambiguation between definite and indefinite reference is effected by word order. As shown by the following examples¹⁰ a noun receives definite interpretation in sentence-initial position and indefinite interpretation in postverbal position (Bongartz 2006).

- Russian
- (9) *Studentka prishla*
student_{NOM} come_{3SG PAST}
'The student came.'
- (10) *Prishla studentka.*
come_{3SG PAST} student_{NOM}
'A student came.'

- Czech
- (11) *Učitelka vidi*
teacher_{NOM} see_{3SG}
'The teacher sees'
- (12) *Vidi učitelka*
see_{3SG} teacher_{NOM}
'A teacher sees.'

As well known, English has both a definite and an indefinite article. However, in English the definite article is generally not used expletively, that is with proper names, demonstrative pronouns, plural generic nouns in subject position, or with complement clauses¹¹. For reasons of economy we refer the reader to the glossed examples (4)-(7) in Section 2 where the discussed cross-linguistic difference is obvious. Unlike its Greek counterpart, the English definite article always bears the interpretable [+definite] feature. Last, in English an indefinite singular count noun must be preceded by the indefinite article, while in the same structure in Greek the use of the article is optional (see example (8) in Section 2).

Romance languages, such as Italian and French, have full articles systems that inflect for gender and number. In French, besides a definite and an indefinite article there is a partitive one. The article systems of these two languages are presented in Tables 3.

¹⁰ The examples in Russian are adapted from Bongartz (2006) and those in Czech from Bongartz (2002:63).

¹¹ Exceptionally, in English the definite article may appear before few geographical names, e.g. the Sudan and generic substantivized adjectives, e.g. the rich and the famous (Longobardi 1994: 631-32). Also it is compulsory before proper names with restrictive modification, e.g., *This is not *(the) Mary I know* and during the Easter of 2000 (Quirk and Greenbaum 1977:78). However, these exceptional uses cannot support a claim for an expletive definite article in English (see Longobardi 1994).

FRENCH						
	<i>indefinite</i>		<i>definite</i>		<i>partitive</i>	
	<i>singular</i>	<i>plural</i>	<i>singular</i>	<i>plural</i>	<i>singular</i>	<i>plural</i>
<i>Masculine</i>	un	des	le	les	du	des
<i>Feminine</i>	une	des	la	les	de la	des
ITALIAN						
<i>Masculine</i>	un/uno	dei/degli	il/lo	i/gli		
<i>Feminine</i>	una	delle	la	le		

Table 3 Articles in French and Italian

Importantly, in both languages the definite article must precede generic plural nouns in subject position (13). Also in Italian a proper noun must be preceded by the definite article if it is premodified by an adjective, or else the definite article is optional (cf. (14) with (15)). On the other hand, in French proper names are canonically not preceded by articles (16).

- (13) *(I) castori costruiscono dighe. Italian
the beavers build dams
*(Les) castors construisent des digues. French
the beavers build part. dams
'Beavers build dams'
- (14) (Il) Gianni mi ha telefonato.
(the) Gianni me has telephoned
'Gianni called me up.'
- (15) *(L') antica Roma
(the) ancient Rome
'Ancient Rome'
- (16) (*Le) Jean m' a téléphoné
Jean me has telephoned
'Jean called me up.'

The above attest to that like in Greek (and unlike in English) the definite articles in Italian and French may bear only uninterpretable features such as gender and number agreement features.

Italian resembles Greek also as to that in object position both massive and singular count nouns complements of a zero article. This is shown by examples (17) and (18) respectively (from Longobardi 1994:613).

- (17) *Bevo sempre vino.*
'I always drink wine.'
- (18) *Mangio patate.*
'I eat/am eating potatoes.'

In French, on the other hand, it seems that bare nouns are generally not acceptable (Longobardi, op. cit.:616, fn 9). For example, in the French equivalents of sentences (17) and (18) the object nouns must be preceded by partitive articles: *Je bois toujours du vin*, *Je mange des pommes de terre*. Table 4 summarizes the main differences and similarities between Greek and the L2 participants' L1s with respect to their article systems.

	ARTICLES	EXPLETIVE ARTICLES
<i>Slavic</i>	-	-
<i>English</i>	+	-
<i>Romance</i>	+	+
<i>Greek</i>	+	+

Table 4 A cross-linguistic comparison of article systems

Also, two native speakers performed the ST task and three the final version of the SR task. Given that their performance in both tasks was perfect we decided not to include these data.

5.2 The tasks

We elicited oral data from a story-telling task and a sentence repetition task (hereafter ST and SR respectively). Both tasks were performed individually in two separate meetings with one of the researchers. In the ST the participants had to narrate a short story for each of eight sequences of pictures¹². The SR consisted of 72 sentences and aimed at testing 6 different conditions for article use. More specifically, we included sentences in which the definite determiner had expletive (specific reference, (19)) and non-expletive (proper name (20), generic reference (21), demonstrative + Def. D (22), Def D. + Comp (23)) uses as well sentences involving the zero determiner (cf. (24) & (25)). For each condition there were 12 sentences, half grammatical and half ungrammatical. Each grammatical sentence differed from its ungrammatical counterpart only regarding the target articles. We give examples of sentences for each condition below. For now let us mention two other important features in the design of this task. Previous research with similar tasks has shown that sentences should long enough to exceed the participants' working memory – otherwise the participants may parrot sentences without understanding their meaning (see references in Vinther 2002:58). Given that sentences of 17 syllables have proved appropriate for advanced L2ers in Erlam (2006), our sentences were 17-22 syllable long, balanced across conditions. This sentence length was decided upon after piloting the task with Greek native speakers. Moreover, the target contexts appeared in middle-sentence position, given the evidence that items in sentence-initial and sentence-final position are more easily recalled (see references in Erlam 2006:477-478). Examples from the SR are presented below where asterisks and parentheses can illustrate both the ungrammatical and grammatical version of each sentence.

Definite article with specific/definite reference

- (19) *den diavasa kanena apo *(ta) vivlia pu aghorasa propersi*
not read-_{1SG} any of (the) books that bought-_{1SG} the year before last
'I didn't read any of the books I bought last year.'

Definite article with proper names

- (20) *Prin tris meres ematha pos *(i) Mary pali pire diazighio*
before three days heard-_{1SG} that (the) Mary again took divorce
'Three days ago I heard that Mary got a divorce again.'

Definite article with generic plural nouns

- (21) *Meriki anthropi lene pos *(i) ghates ine poli aharista zoa*
some people say that (the) cats are very ungrateful animals
'Some people say that cats are very ungrateful animals.'

Definite article with demonstrative pronouns

- (22) *Aghorasan se kali timi afto *(to) spiti epidi itan poli palio*
bought-_{3PL} at good price this (the) house because was very old
'They bought this house at a good price because it was very old.'

Definite article before a complementizer

- (23) *den kani tipote alo apo *(to) na jimnazete sinexia*
not does-_{3SG} nothing other than from (the) to exercise-himself all the time
'He does nothing but exercising himself all the time.'

Zero article

- (24) *Otan itan nea ekane *(ta) taksidia poles fores kathe mina*
when was-_{3SG} young did-_{3SG} (the) trips many times every month
'When she was young she traveled many times per month.'
- (25) *den ine sosto na trome *(ti) zahari se meghales posotites*
not is right to eat (the) sugar in big quantities

¹² The pictures were the same as those used in Dimitrakopoulou et al. (2004). We thank Ianthi-Maria Tsimpli for providing us with these pictures.

'It's not right to eat sugar in big quantities.'

The sentences were randomized in two equal parts, one for each of the meetings between the participants and the researcher. Prior to testing, the sentences had been recorded by a native speaker and stored on a laptop computer. The participants were told they had to listen to sentences and repeat them as fast as possible and that if they thought a sentence was ungrammatical they were expected to repeat what they considered as its grammatical version. Responses (from the ST too) were documented on a digital tape recorder.

5.3 Results

We first present the results from the ST task. The data were analyzed with respect to the three types of articles, hereafter called 'determiners': definite, indefinite and zero. For each determiner, the obligatory contexts were identified and the participants' response was coded. Table 5 illustrates correct performance on each determiner type for all L2 groups.

L2 GROUPS	Definite D.	Indefinite D.	Zero D.
ENGLISH	99 (669/674)	96 (139/145)	99 (191/192)
ROMANCE	97 (455/467)	97 (124/128)	98 (91/93)
SLAVIC	96 (536/559)	86 (74/86)	89 (89/100)

Table 5 Correct performance on the ST task (raw scores in parentheses)

Turning first to the data from the definite determiner, all three groups performed highly accurately, above 90%, which indicates mastery of its use. However, the non-parametric chi-square test showed that the English group significantly outperformed both the Romance ($\chi^2(1)=6.279$, $p=.012$, Cramer's $V=.074$) and the Slavic ($\chi^2(1)=15.661$, $p=.000$, Cramer's $V=.113$) group. Moreover, all participants' errors involve omissions of the definite determiner and never incorrect suppliance, i.e. the use of the indefinite article.

The data from the indefinite determiner point out that the Slavic group exhibits certain difficulties with the use of the indefinite determiner, since it is the only group that performs below 90% on the indefinite determiners. This observation was statistically verified, as the Slavic group achieved a significantly lower score than the English ($\chi^2(1)=4.937$, $p=.026$, Cramer's $V=.147$) and the Romance ($\chi^2(1)=6.339$, $p=.012$, Cramer's $V=.173$) group. Moreover, the use of the indefinite determiners is significantly harder than that of the definite ($\chi^2(1)=14.060$, $p=.000$, Cramer's $V=.148$) determiners for this group. Additionally, the English and the Romance speakers' errors consist of omissions and not substitutions, whereas the Slavic speakers erroneously supplied the definite article in two contexts.

The same pattern is attested in the zero determiner contexts; namely the Slavic group performs significantly lower than the English ($\chi^2(1)=18.323$, $p=.000$, Cramer's $V=.250$) and the Romance ($\chi^2(1)=6.007$, $p=.014$, $\eta^2=.176$, Cramer's $V=.176$) groups and its performance just misses the 90% threshold. Furthermore, the participants' incorrect responses include incorrect suppliance of the definite article.

Next, we turn to the data collected from the SR task. For the present study, the data were coded only with respect to the production of the determiners. Consequently, correct elicitation of the definite or the zero determiner was coded as "1" and incorrect as "0". Table 6 provides the participants' correct performance on the definite and zero determiners for each language group.

L2 GROUPS	Definite Determiner		Zero Determiner	
	grammatical	ungrammatical	grammatical	ungrammatical
ENGLISH	0.87 (0.10)	0.81 (0.10)	0.97 (0.07)	0.67 (0.41)
ROMANCE	0.86 (0.09)	0.85 (0.13)	0.97 (0.07)	0.53 (0.25)
SLAVIC	0.80 (0.12)	0.59 (0.14)	0.83 (0.16)	0.44 (0.25)

Table 6 Correct performance on the SR task (SDs in parentheses)

As shown in Table 6, all L2 groups perform better on the grammatical than the ungrammatical sentences, a finding which is more pronounced in the zero determiner condition. Besides, the Slavic group exhibits the lowest performance in both determiners. We conducted a 2x2 Repeated measures ANOVA with Determiner (definite vs zero determiner) and Grammaticality (grammatical vs.

ungrammatical sentences) as the within-subjects variables and Language (English, Romance and Slavic groups) as the between-subjects variables, in order to test for main effects and interactions. The statistical analyses showed that the main effects of Grammaticality ($F(1,15)=25.272$, $p=.000$, $\eta^2=.628$), Language ($F(2,15)=5.117$, $p=.020$, $\eta^2=.406$) and the interaction between determiner and grammaticality ($F(1,15)=16.377$, $p=.001$, $\eta^2=.522$) were significant. The Bonferroni post-hoc tests applied to detect any language contrasts demonstrated that the Slavic group was significantly less accurate than the English group ($p=.030$) and only marginally less accurate than the Romance group ($p=.067$). Furthermore, paired-samples t-tests indicated that the grammatical sentences were elicited significantly more precisely than the ungrammatical ones in the definite ($t=3.282$, $p=.004$) and the zero ($t=4.847$, $p=.000$) determiner conditions.

A further analysis was run on the data in order to explore whether any differences were attested between the expletive and the non-expletive uses of the definite determiner.

Uses of Def. D.	English	Romance	Slavic
Expletive use			
Specific			
Grammatical	1 (0)	1 (0)	0.78 (0.25)
Ungrammatical	0.83 (0.21)	0.94 (0.14)	0.67 (0.21)
Non expletive uses			
Proper name			
Grammatical	0.97 (0.07)	1 (0)	0.89 (0.14)
Ungrammatical	1 (0)	0.97 (0.07)	0.69 (0.19)
Generic reference			
Grammatical	1 (0)	0.97 (0.07)	0.97 (0.07)
Ungrammatical	1 (0)	1 (0)	0.86 (0.19)
Demonstrative + Def. D.			
Grammatical	0.92 (0.09)	0.81 (0.19)	0.63 (0.2)
Ungrammatical	0.92 (0.09)	0.83 (0.15)	0.64 (0.34)
Def. D. + Comp.			
Grammatical	0.44 (0.39)	0.53 (0.44)	0.14 (0.16)
Ungrammatical	0.31 (0.37)	0.50 (0.49)	0.08 (0.14)

Table 7 Correct performance on expletive and non-expletive uses on the SR task (SDs in parentheses)

The data of Table 7 illustrate that the structures involving the use of the definite determiner with a demonstrative and with a complementizer triggered the most inaccurate responses. A 5x2 Repeated measures ANOVA with Definite determiner (specific, vs proper name vs generic reference vs demonstrative + Def. D vs Def D. + Comp) and Grammaticality (grammatical vs ungrammatical sentences) as the within-subjects variables and Language (English vs Romance vs Slavic groups) as the between-subjects variable was run on the data in order to uncover possible main effects and interactions. The main effects of Definite determiner ($F(4,12)=13.294$, $p=.000$, $\eta^2=.816$), Grammaticality ($F(1,15)=12.646$, $p=.003$, $\eta^2=.457$) and Language: $F(2,15)=8.749$, $p=.003$, $\eta^2=.538$) were statistically significant. Bonferroni post-hoc tests used to test for significant differences among the language groups showed that the Slavic group was significantly less accurate than the English ($p=.010$) and the Romance ($p=.006$) groups. Further Bonferroni post-hoc tests employed to explore the main effect of the Definite determiner indicated that the Definite + Comp condition was significantly less accurate than all other structures ($p=.000$: for all structures with the exception of the structure Demonstrative + Def. D: $p=.001$). Besides, the L2 speakers' performance on the demonstrative + Def. D. condition was significantly lower than that involving a proper name ($p=.012$) and the one in which the definite determiner had generic reference ($p=.004$).

6. Conclusion

The focal aim of this study was to assess the predictions of the IH by comparing three L2 groups' performance on the production of determiners in L2 Greek. The two groups' first language grammaticalizes the feature [definiteness], whereas the Slavic group's first languages (Czech and Russian) do not. Our main research question was whether the Slavic speakers who had been living in Greece for at least 18 years and, therefore, have had massive exposure to Greek, can acquire LF-uninterpretable features lacking from their L1. The findings of the ST task suggest that they can, since

their performance on the production of the definite determiners exceeded the 90% threshold. Moreover, the Slavic group was more accurate on the definite than the indefinite determiner, contrary to the predictions of the IH based on the assumption that the indefinite determiner incorporates interpretable features. In addition to this, the English group performed significantly better than the Romance and the Slavic groups on the definite determiner, which argues against the hypothesis that speakers of L1s with articles *and* expletive uses of the definite article (Romance speakers) would fare better than those whose L1 has no expletive articles (English speakers) and even better than those from an articleless L1 (Slavic speakers). Therefore, the results from the ST task argue against the IH and indicate that interpretable features may also constitute a source of deficits in the second language.

However, the data from the SR task illustrate a somehow different picture. The first issue we want to focus on is the difference between the ST and the SR tasks as far as the L2 groups' correct performance is concerned. In particular, the L2 speakers manifested more difficulties with the determiners in the SR than in the ST task, with these difficulties being more prominent in the Slavic group. Besides, the Slavic group demonstrated lower accuracy on the definite determiner condition than the two other groups. Even though these results from the SR task are in line with the predictions of the IH, it is not clear why the same pattern was not observed in the ST task. One possible explanation for the divergent results in the ST and the SR tasks is the nature of the tasks themselves. The ST task allows the speakers to choose their utterances and avoid structures they feel hesitant about. On the other hand, the SR task is a more demanding task in terms of the resources required from the participant and is supposed to reflect implicit knowledge (Gallimore & Tharp 1981; Weitze et al. 2011). Our data suggest that when automaticity is required, the non native speakers do not exhibit native-like performance; for example, all groups' performance on the SR task is below 90% (at least on the definite condition). Moreover, we maintain that in such demanding conditions the difficulties L2 speakers experience with uninterpretable features that are absent from their L1 appear more pronounced.

A final issue we would like to discuss is the effect of particular constructions on the participants' performance. More specifically, the three groups do not manifest any qualitative differences among each other in the SR task, in the sense that the most problematic structures for all groups are the ones involving the use of the definite determiner with a demonstrative and particularly with a complementizer. In the latter structure, even the English and the Romance groups perform at chance level. Notice that the definite determiner is not allowed to appear in front of a complementizer in the L1 of either group, which may have affected the participants' performance. Besides, Roussou (1991) argues that the category D in Greek may select a CP. It may, hence, be the case that the selection properties of D are not native-like in the L2 speakers of this study. An alternative account of nominalised CPs in Greek has been put forward by Tsimpli & Stavrakaki (1999). According to this explanation, the prepositioning of the definite determiner in nominalised CPs is entailed by the strong morphological requirement of Greek for Case. More specifically, it is argued that the function of the definite D in nominalised clauses is to convert the clause into a DP argument and to carry its case features. The absence of this option in the participants' L1s may have resulted in the attested difficulties with nominalised clauses. +

The inquiry and the implications of these two possibilities are left open for further research.

RESULT CLAUSES IN ANCIENT GREEK

Irene Appelbaum

University of Montana

Missoula, MT, USA

irene.appelbaum@umontana.edu

ABSTRACT

Result clauses in Ancient Greek are traditionally distinguished in terms of whether they express actual or possible results. After clarifying the sense of possibility being invoked in this distinction, I argue (i) that this notion of possibility functions as a presupposition rather than an assertion of natural result clauses, and (ii) that it cannot be the basis for distinguishing the two clause types, because it is a presupposition of actual result clauses as well. Based on an examination of result clauses in Lysias, I then argue that an alternative account of the relationship between the two clause types deserves further attention.

Keywords: result clauses, Ancient Greek, possibility, presupposition

1. Introduction: Overview of the Traditional Account

In the most general terms, a result clause is a type of subordinate clause which specifies a state or event as the result of a state or event specified in the main clause.¹ In Ancient Greek, result clauses are introduced by the conjunction ὥστε (also: ὥστ', ὥσθ'), *that, so that, as, so as*, and main clauses usually contain an adjectival or adverbial element of degree or kind, such as οὕτως, *so, thus*; τοσοῦτος, *so much, so great*; or τοιοῦτος, *of such a kind*. An example from Plato follows:

- (1) ἐγὼ μὲν οὖν ὅταν σοὶ συγγένωμαι, οὕτω διατίθεμαι ὥστ' ἐμοὶ δοκεῖ μανίαν εἶναι...
When I am in your company I am so affected, that I think it is madness(Euthydemus 306d).²

Grammars of Ancient Greek distinguish two types of result clause: natural result and actual result. While both types conform to the above pattern – a main clause specifying degree or kind, followed by a subordinate clause introduced by ὥστε – they differ formally in terms of whether the verb in the result clause is finite or infinitival. An actual result clause contains a finite verb and a natural result clause has an infinitive verb. Additionally, they differ in terms of how they are negated: actual result clauses are negated with οὐ, and natural result clauses are negated with μή. Examples (2) and (3) are negated examples of result clauses of each type:

- (2) Negated Actual Result Clause
ἐγὼ δὲ οὕτω πολλοῦ ἐδέησα τῶν τετρακοσίων γενέσθαι, ὥστε οὐδὲ τῶν πεντακισχιλίων κατελέγην.
so far was I from being one of the Four Hundred that I was not even included in the list of the Five Thousand (Lysias 30.8).
- (3) Negated Natural Result Clause
οὕτως ῥηκοῦμεν δημοκρατούμενοι ὥστε μήτε εἰς τοὺς ἄλλους ἐξαμαρτάνειν μήτε ὑπὸ τῶν ἄλλων ἀδικεῖσθαι.

¹ I thank John Hay, Joslin Monahan, Tully Thibau and the audience at ICGL10 for helpful questions and discussion.

² Unless otherwise indicated, translations of Lysias are from Lamb (1930); translations for other authors are listed in the References.

*we have lived in **such a way** under democracy **so as neither to err** against others **nor to be wronged** by others* (Lysias 12.5, translation my own).

Correlative to the formal difference between natural and actual result clauses, a functional or semantic difference is traditionally recognized. While an actual result clause is said to assert the result as a factual occurrence, a natural result clause is said to present the result as a possible occurrence. This distinction is made explicit in the following descriptions:

A clause of result with ὥστε stating that something may occur...is regularly expressed with the infinitive (Smyth 1984, sec. 2258).

The infinitive with ὥστε denotes an anticipated or possible result... (Smyth 1984, sec. 2260).

[T]he dependent clause [in a natural result clause] in principle expresses a possible consequence (Rijksbaron 2002, 63).

2. A Closer Look at the Traditional Account

2.1 Possibility as Ability

The sense of "possible" result or consequence being invoked in the above descriptions is not transparent. One interpretation that presents itself is that "possibility" is being used in the sense of "ability". On such an interpretation, possibility makes a claim about conditions on the agent (see Bybee et al. 1994, 177-179). On this reading, the event expressed in a natural result clause is possible in the sense that it is enabled by conditions that pertain to the agent. For example, (4) below, which contains an actual result clause, asserts that, as a consequence of the high level of audacity identified in the introductory clause, they are in fact coming here ready to defend themselves.

- (4) *καὶ εἰς τοσοῦτόν εἰσι τόλμης ἀφιγμένοι ὥσθ' ἤκουσιν ἀπολογησόμενοι*
*and they have carried audacity to **such a pitch that they come here** ready to defend themselves* (Lysias 12.22).

If we now replace the finite verb ἤκουσιν in example (4) with the infinitival form ἤκειν, we obtain a natural result clause. According to the present interpretation of possibility as ability, this result clause asserts that, as a result of the antecedently expressed high level of audacity, they *are able to* come here ready to defend themselves. We might translate this natural-result-clause equivalent of example (4) as: *And they have carried audacity to such a pitch as to be able to come here ready to defend themselves.*

While the interpretation of possibility as ability seems to play a role in some result clauses, it is unlikely to be the main interpretation of possible occurrence in natural result clauses. This is so both because there are many clauses where ability is not relevant to the predicate expressed, and because in cases where ability clearly is part of the intended meaning of natural result clauses, it is usually expressed lexically, with the predicate δύναμαι. Example (5) below is illustrative:

- (5) *οὕτω διετέθημεν οἱ παρόντες ὑπὸ τῶν τούτῳ πεπραγμένων καὶ τῶν λόγων τῶν ἐκείνης...*
ὥστε...μηδένα τῶν παρόντων δύνασθαι φθέγγασθαι...
*all of us present were **so** moved by the deeds done by this man and by her words...so as for no one among us present **to be able** to utter a sound...* (Lysias 32.18, translation my own).

In addition, δύναμαι, is also used to express ability in actual result clauses, as in example (6) below:

- (6) *οὕτω σκαιὸς εἶ καὶ ἀναίσθητος, Αἰσχίνη, ὥστ' οὐ δύνασαι λογίσασθαι ὅτι τῷ μὲν στεφανουμένῳ τὸν αὐτὸν ἔχει ζῆλον ὁ στέφανος...;*
*are you **so** unintelligent and blind, Aeschines, **that you are incapable** of reflecting that a crown is equally gratifying to the person crowned...?* (Demosthenes, *Orations* 18.120).

To summarize: if we understand the central semantic difference between natural and actual result clauses as the difference between *able to do X* and *does X*, we are left without an account of the difference in meaning between natural result clauses containing an additional lexical expression of possibility with δύναμαι, and the more frequent case where ability is expressed formally. Additionally, we are left without an account of the meaning of clauses where ability is not even a candidate explanation of "possible occurrence".

2.2 Possibility as Epistemic Modality

Another interpretation of the sense of possibility implied in the description of natural result clauses as expressing possible as opposed to factual occurrences is that it is a type of epistemic modality. In contrast to the agent-oriented ability discussed above, epistemic possibility is not part of the content of the utterance (see Bybee et al 1994, 179-180). Instead, it makes a claim about the speaker's relation to the content of the utterance - in particular, that the speaker is only partly committed to, or confident of, its truth. The traditional description of natural result clauses as expressing events that "may occur" or that are "possible consequences", suggests that epistemic possibility is indeed the intended interpretation of what is expressed by natural result clauses. However, this is unlikely to be the intended interpretation. For the usual way of expressing such modality in Ancient Greek is with a finite verb in the optative mood and the particle ἄν. Such so-called "potential optative" constructions (see (7) and (8) below) serve precisely the role of weakening the speaker's epistemic commitment to the truth of the proposition.

- (7) πολλοὶ γὰρ ἄν γένοιτο.
*There **might** be many ways* (Plato, *Republic* 449c).
- (8) συνδοκεῖ καὶ ὑμῖν, γένοιντο ἄν ἡμῖν ἐν λόγοις ἰκανὴ διατριβή.
*So if you on your part approve, we **might** pass the time well enough in discourses*
 (Plato, *Symposium* 177d).

2.3 Possibility as Natural Tendency

If it is neither agent-oriented ability nor epistemic modality that is being referenced when natural result clauses are identified as expressing possible rather than actual results, what sense of possibility is intended? What seems to be intended is the claim that natural result clauses express natural tendencies. That is, instead of expressing the claim that an event may have occurred rather than asserting that it did occur, natural result clauses, on this view, express the fact that such an event tends to be the result of the antecedently expressed condition, or that it is what "usually" or, as the name implies, "naturally" results from such conditions.

As Goodwin says:

With the infinitive the result is one which the action of the leading verb tends to produce; with the indicative, one that action does produce (Goodwin 1894, sec. 1450).

The connection between possible result and natural tendency seems, then, to be the following: Given that the action of the leading verb tends to produce, or naturally produces, the result indicated in the result clause, it is possible that it produces that result in the present case as well.

So, as we noted at the beginning of this section, the sense of possibility invoked in the claim that natural result clauses express possibilities, is not the most transparent one. But we have now made this sense of possibility explicit and we can now reformulate the traditional distinction between actual and natural result clauses as follows: *An actual result clause expresses the result as one that in fact occurs or occurred, whereas a natural result clause expresses the result as one that tends to occur.*

Nevertheless, in the next section I argue that this view does not capture the central distinction between natural and actual result clauses.

3. Criticism of the Traditional Account

3.1 The Natural Tendency is a Presupposition

In this section I argue that the traditional view of natural result clauses as expressing possible occurrences or natural tendencies is problematic both because (i) such natural tendencies are not assertions of natural result clauses, but rather are presupposed by them; and (ii) they are presupposed equally by actual result clauses and hence cannot be used to distinguish the two types of clause.

We can show that the relevant natural tendency (or possible occurrence) is a presupposition, by invoking a classic test for identifying the presuppositions of a statement: the constancy-under-negation test. In Levinson's description of the test, we "[s]imply take a sentence, negate it, and see what inferences survive – i.e., are shared by both the positive and negative sentence" (Levinson 1983).

Let us apply this test to the natural result clause in example (9):

- (9) *She was so hungry as to eat the whole pie.*

In this sentence a quasi-causal connection is made between extent of hunger and extent of pie eating, such that an increase in hunger, leads to an increase in amount of pie consumed, and in the limit case, to the consumption of the whole pie. In other words, we may say: as a person's hunger increases, there is a natural tendency for the person to eat more, in the present case, of the pie, and if hunger increases sufficiently, for it to result in the eating of the whole pie.

But if we now negate the sentence:

- (10) *She was not so hungry as to eat the whole pie,*

the quasi-causal connection between an increase in hunger and an increase in pie-eating behavior is maintained. The negated version of the sentence also claims that there is a natural tendency for more pie-eating to occur as one's hunger increases and for the whole pie to be eaten if hunger increases sufficiently. The negated version of the sentence simply denies that a sufficient degree of hunger is present.

The claim that there is a natural tendency for an increase in hunger to result in an increase in amount of pie eaten is an inference that survives the constancy under negation test. It is therefore a presupposition rather than an assertion of the natural result clause expressed in (9) above. And we may say, more generally, that the natural tendencies associated with natural result clauses are presuppositions of such clauses rather than assertions.

It is important to recognize what triggers the presupposition in statements such as the above. It is the form of the statement, and specifically, the formula $\text{o}\tilde{\upsilon}\tau\omega\varsigma X, \tilde{\omega}\sigma\tau\epsilon Y$ (*so X, as to Y*).

We can make this clear by substituting a different result in our example sentence:

- (11) *She was so hungry as to solve all the problems.*

The sentence makes little sense precisely because there is no natural tendency for a high degree of hunger to be associated with a high level of problem-solving ability. Indeed, to the extent that such a sentence does make sense, it is because we posit a context which supplies a plausible connection between the state of being hungry and the act of problem-solving: such as one in which solving all the problems leads to receiving food. The important point here is that it is in virtue of the formula $\text{o}\tilde{\upsilon}\tau\omega\varsigma X, \tilde{\omega}\sigma\tau\epsilon Y$ (*so X, as to Y*) that the sentence requires positing an additional context for it to make sense. In other words, it is in virtue of the form of the statement that a quasi-causal connection, or natural tendency, between hunger and problem-solving ability is assumed.

We can summarize what has been argued so far as follows: (i) the traditional view that natural result clauses express possible results is intended as the claim that natural result clauses express a natural tendency of one event or state to result in another; (ii) this natural tendency is not, however, what natural result clauses express or assert, but something they presuppose; and (iii) this presupposition holds in virtue of the form of such statements - the form $\text{o}\tilde{\upsilon}\tau\omega\varsigma X, \tilde{\omega}\sigma\tau\epsilon Y$ (*so X, as to Y*).

3.2 Actual Result Clauses Have the Same Presupposition

The points summarized above would amount to simply clarifying the traditional view of how natural result clauses differ from actual result clauses were it not for the fact that actual result clauses have the

same form and trigger the same presupposition. It is true that the English gloss of the formula *ὅπως X, ὥστε Y* would be different for an actual result clause (*so X, that Y* instead of *so X, as to Y*) but this makes no difference to the formula's status as a presupposition trigger.

- (12) *Positive: She was so hungry that she ate the whole pie.*
Presupposes that increased hunger naturally tends to produce increased eating.
- (13) *Negative: She was not so hungry that she ate the whole pie.*
Presupposes that increased hunger naturally tends to produce increased eating.

It is here that the problem for the traditional view becomes clear. The difference between natural and actual result clauses cannot be the difference between asserting a possible occurrence and asserting a factual occurrence, as the traditional view maintains, not simply because natural result clauses presuppose rather than assert possible occurrences (in the form of “natural tendencies”), but because actual result clauses have the same presupposition. In other words: this cannot be the basis for the distinction because it does not distinguish them.

4. Towards a Revised View of Natural Result Clauses

4.1 Hypothesis

From what has been said thus far we seem poised to state the difference between natural and actual result clauses in the following terms: While all result clauses presuppose a quasi-causal connection (“natural tendency”) between the event or state identified in the introductory clause and the event or state expressed in the result clause, actual result clauses additionally state that this connection or tendency is realized in the present case, while natural result clauses make no such additional assertion.

The difficulty with this way of putting the distinction, though, is that it suggests that natural result clauses are simply agnostic about whether the expected result is in fact realized, and this is simply too weak an interpretation. For even in traditional descriptions, there is an acknowledgement that a natural result clause may (after all) indicate a factual occurrence. Smyth, for example, says: “The infinitive may therefore denote a fact...” (Smyth 1984, sec. 2258)

Here and elsewhere such claims are tempered by subsequent statements:

The infinitive may therefore denote a fact, but does not explicitly state this to be the case (Smyth 1984, sec. 2258).

[T]he actual occurrence of the result is not stated, and is to be inferred only (Smyth 1984, sec. 2260).

Whether or not the consequence actually came about is not explicitly indicated. (Rijksbaron 2002,63)

In these statements we seem to have the basis for a more nuanced account of the difference between natural and actual result clauses. The difference between the two clause types, according to the present hypothesis is not whether the statement implies that the result is factual, but rather whether this inference is defeasible. That is, the assumption is assumed to be true or factual, but further information might reverse, or defeat this assumption. While we may say:

- (14) *She was hungry enough to eat the whole pie, but she didn't eat the whole pie,*

it is a contradiction to say:

- (15) **She was so hungry she ate the whole pie, but she didn't eat the whole pie.*

On the current interpretation, then, we can say that the difference between the two clauses is whether the result is logically implied (in actual result clauses) or defeasible (in natural result clauses). This interpretation seems to be a way to accommodate the intuition embodied in the traditional view that natural result clauses make a weaker claim than actual result clauses do, while also acknowledging that natural result clauses often imply factual results.

4.2 Textual Investigation

Unfortunately, empirical examination of result clauses in the corpus of Lysias's *Speeches*, did not support the above interpretation. In fact, there was virtually no evidence that natural result clauses were used in cases where it was necessary or desirable to preserve the possibility that the implied result was not the result, in fact. The strongest evidence of this sort would be an example along the lines of (14) above, where subsequent statements force a re-evaluation of the claim that the result, in fact, occurred. But there were no examples of this sort.

Instead, for the most part, the natural result clauses seemed to fall into two classes. In one class of cases, they seemed indistinguishable from correlative actual result clauses. In this class of cases, the use of an infinitive in the result clause did not seem to indicate any possibility that the result was not factual. These examples were relatively few, but include (16) and (17) below.

- (16) *πρὸς τὸν ἀδελφὸν δ' οὕτως ἐνειμάμην ὥστ' ἐκεῖνον πλέον ὁμολογεῖν ἔχειν ἐμοῦ τῶν πατρῶων*
*to my brother I allowed **such** a portion **as made him** acknowledge that he had got a larger share of our patrimony than I had* (Lysias 16.10).
- (17) *οὗτος δὲ ἀπέδειξε δυοῖν δεούσας πεντήκοντα μνᾶς ἀνηλωκένας, ὥστε τοῦτοις λελογίσθαι ὅσον περ ὅλον τὸ ἀνάλωμα αὐτῷ γεγένηται.*
*But the expenditure that he showed was forty-eight minae, **so that the children have been charged** exactly the total of what he has spent* (Lysias 32.27).

In (16) it is conceivable that the amount the speaker gave to his brother, though sufficient to make his brother acknowledge the larger share, did not in fact result in his brother being made to acknowledge the larger share. But the context makes clear that the speaker is referring to an actual event. So the choice of infinitive over finite verb may simply be due to a desire to emphasize the event in the main clause — the speaker's action.

Similarly, in example (17), the speaker is arguing precisely that the event stated in the result clause — the children being charged an amount equal to what the guardian has spent — is indeed a fact. The context here is a lawsuit against a guardian — Diogeiton — who is accused of cheating the children out of their inheritance. In the above passage, the claim is he charged 100% of an expenditure to the children when he was allowed to charge them only 50%. The cost was 48 minae, so he was allowed to charge only 24 minae to the children. However, he entered 48 minae into the ledger: with the result that the children were charged the whole amount. The facts of the case against the guardian are being presented here, as fact.

Examples such as these make it difficult to endorse Goodwin's claim that: "These two constructions [natural and actual result clauses] are essentially distinct in their nature, even when it is indifferent to the general sense which is used in a given case" (Goodwin 1894, sec. 1451).

The second classes of cases is both more numerous and more interesting. In these cases, the event or state in the result clause is distinguished by the fact that it is in some way non-actual. However, the non-actuality in these cases is not a function of epistemic possibility, or probability, but rather of the event specified in the result clause occurring in a counter-factual context, or having a negative subject. In other words, the non-actuality attaches to the event or state itself, not to the statement reporting the event.

An example of a natural result clause occurring in the context of a counterfactual statement is the following:

- (18) *τοιαῦτα γάρ ἐστιν, ὥστ' εἰ καὶ μηδὲν αὐτῷ ἄλλο ἡμάρτητο, διὰ μόνα ταῦτα δίκαιον εἶναι ἀποδοκιμασθῆναι.*
*For the facts are **of such a sort, that even if he had not erred in any other matter, on account of these facts alone, it would be just for him to be rejected*** (Lysias 31.20, translation my own).

Following ὥστ', but before the subordinate result clause, is a protasis of a counterfactual condition signaled by the particle εἰ and the verb ἡμαρτάνω in the indicative (here, the pluperfect). The counterfactual clause assumes that other wrongdoings have in fact been committed, with the implication that the case for rejecting the man is even stronger than it would have been had there been no additional wrongful deeds. But for present purposes what is important is that εἶναι in the phrase δίκαιον εἶναι is in the infinitive, not because the speaker has any doubt about whether there are

currently grounds for rejecting the man, but because the clause is making a claim about the justice of rejecting him in a counterfactual state of affairs - one in which the decision to approve or reject the man is made in the absence of additional wrongdoings. There is no way for this clause to be formulated as an actual result, but not because the state identified in the result clause — it being just to reject the man — is only a possible consequence. On the contrary, it is certain — certain that it is not a consequence, because the antecedent of the clause is counterfactual.

Example (5) above, repeated here as (19) contains a natural result clause with a negative subject:

- (19) οὕτω διετέθημεν πάντες οἱ παρόντες ὑπὸ τῶν τούτῳ πεπραγμένων καὶ τῶν λόγων τῶν ἐκείνης... ὥστε... **μηδένα** τῶν παρόντων **δύνασθαι** φθέγγεσθαι...
*all of us present were **so** moved by the deeds done by this man and by her words,...**so as** **for no** one among us present **to be able** to utter a sound...* (Lysias 32.18, translation my own).

In this case, it is clear from what follows that what is being reported is not merely a possible occurrence:

- (20) ...ἀλλὰ καὶ δακρύνοντας μὴ ἦτον τῶν πεπονθότων ἀπιόντας οἷχεσθαι σιωπῇ.
...we could only weep as sadly as the sufferers, and go our ways in silence (Lysias 32.18)

Yet what is reported is the *absence* of an event— the absence of anyone uttering a word. What seems to be crucial in this case and other cases of this sort, is not so much that a particular individual failed to perform a particular action (for there are many *actual* result clauses of this sort), but that there is no individual specified in definite terms to perform — or even fail to perform — the action. In (19), the subject of the introductory clause is the group of individuals present, but the subject of the result clause is "no one" (*μηδένα*).

It is clear that the examples and analysis provided in this section represent only a preliminary attempt to characterize in positive terms, the different functional yields of natural and actual result clauses in Ancient Greek. Yet I hope enough has been said so as to justify the conclusion that more analysis is needed.

AN ARTICULATORY STUDY OF WORD-INITIAL STOP GEMINATION IN CYPRIOT GREEK

Spyros Armosti

University of Cyprus

armostis@cantab.net

ΠΕΡΙΛΗΨΗ

Σε γλώσσες που επιτρέπουν άηχα διπλά κλειστά σύμφωνα στην αρχή των λέξεων, η ακουστική διάρκεια της κλειστής φάσης (που αποτελεί την κύρια ένδειξη για το διπλασιασμό των συμφώνων) δεν μπορεί να εντοπιστεί μετά από παύση (δηλ. στην αρχή του εκφωνήματος). Ωστόσο, αρθρωτικά η διάκριση εξακολουθεί να υπάρχει (Kraehenmann και Lahiri 2008), ενδεχομένως με προσωδιακή επιμήκυνση στην αρχή του εκφωνήματος. Η παρούσα έρευνα εξετάζει αν στη θέση αυτή διατηρείται η αρθρωτική διάκριση μεταξύ απλών και διπλών στην κυπριακή ελληνική. Παρουσιάζονται τα αποτελέσματα ηλεκτροπαλτογραφημάτων, που δείχνουν ότι η αρθρωτική διάκριση υφίσταται, αλλά υπόκειται σε περιορισμούς που σχετίζονται με τη θέση του τόνου. Η διάκριση είναι ωστόσο σαφώς ακουστικά αντιληπτή λόγω της μεγαλύτερης διάρκειας της δασύτητας του διπλού κλειστού.

Λέξεις κλειδιά: Κυπριακή ελληνική, διπλά σύμφωνα, αρθρωτική φωνητική.

1. Purpose of the study^{*}

The contrast between geminate and singleton consonants is usually defined in terms of differences in the duration of the consonant. However, for a variety of languages, research on singleton vs. geminate contrasts has suggested that the gemination contrast is not signalled solely by durational differences; rather, the phonetic implementation of gemination may involve additional language-specific acoustic properties such as temporal and non-temporal characteristics of the consonant *per se* as well as its adjacent vowels.

In the literature focusing particularly on the gemination contrast of voiceless stops, the duration of the closure (CD) is considered to be the primary cue to the contrast. For example, Abramson showed that, in Pattani Malay, longer CD was the main phonetic correlate for word-initial geminates both acoustically (Abramson 1998), and perceptually (Abramson 1986). However, phrase-initially, where the silent occlusion of stops is acoustically and perceptually non-detectable, listeners successfully distinguished singleton from geminate stops by relying on two secondary cues, namely, RMS amplitude of the syllable whose onset was the target stop (Abramson 1991), and fundamental frequency of the vowel following the word-initial stop (Abramson 2004). In Cypriot Greek, aspiration functions as a strong acoustic correlate of stop and affricate gemination (cf. e.g. Armosti 2011a and the relevant literature reviewed therein).

In languages that allow word-initial voiceless geminate stops, the acoustic duration of the closure cannot be perceptually detected after a pause (i.e. phrase-initially); thus, if there are no secondary acoustic cues to gemination (such as the above-mentioned acoustic correlates), the contrast can be expected to be acoustically and perceptually neutralised. However, recent studies have shown that, even though the gemination contrast is neutralised acoustically and perceptually (in cases that no significant secondary cues to gemination exist), *articulatorily* the distinction still holds in languages such as Tashlhiyt Berber (Ridouane 2007), Tarifit Berber (Bouarourou *et al.* 2008), and Swiss German (Kraehenmann and Lahiri 2007; 2008). In these articulatory studies, it was shown that word-initial geminates were systematically longer in their articulation than their singleton counterparts, both phrase medially and initially (despite of the fact that in the latter case there was no acoustic difference in duration between singleton and geminate stops). An equally important finding of those studies was that

^{*}I am grateful to Francis Nolan, Elinor Payne, Mary Baltazani, as well as to the anonymous reviewer of this paper for their valuable comments and suggestions.

stops were longer in phrase-initial position than in phrase-medial, a finding that was interpreted as prosodic lengthening (and strengthening in cases whereby it involved more linguopalatal contact).

Payne (2006) also reported that the acoustic and articulatory implementation of gemination in Italian involved longer consonant duration as well as greater linguopalatal contact and the use of different regions of articulators. Based on these findings, Payne (2006) analysed gemination in Italian as a fortitional (i.e. strengthening) process. While fortition characterising the gemination contrast can be considered a phonological process, fortition governed by prosodic factors (such as position in the word or phrase, stress, and intonational focus) can be considered a phonetic process, which is expected to be operative across languages.

Thus, lengthening and strengthening effects of prosodic factors on stops are expected to manifest acoustically and articulatorily in Cypriot Greek also. Furthermore, these phonetic effects may interact with possible strengthening effects that may accompany the phonological contrast of stop gemination. Since in Cypriot Greek, the gemination contrast of voiceless stops is acoustically and perceptually maintained even in absolute initial position because of the presence of long aspiration (which is a strong cue to gemination), it would be interesting to investigate whether the contrast is also articulatorily maintained phrase-initially (as was shown above for other languages).

These aspects of the articulation of CyGr stop gemination are investigated in this paper. In particular, the acoustic durational contrast between singleton and geminate stops is expected to be mirrored at the articulatory level in terms of the length of articulation, even in utterance-initial position. Furthermore, singletons and geminates are expected to differ not only durationally, but also spatially, i.e. in terms of the location, shape, and size of the linguopalatal contact. Finally, both singletons and geminates are expected to be longer and stronger in strong prosodic positions, such as utterance-initial position and when stressed.

2. Method

2.1. Electropalatography (EPG)

To obtain the desired articulatory information, Electropalatography (EPG) was used. EPG is an instrumental technique for recording information about the tongue's contact with the hard palate during speech. In EPG, the subject is required to wear a thin acrylic palate that is uniquely designed to fit the roof of their mouth; the artificial palate is embedded with electrodes, which serve as sensors for tongue contact (see e.g. Hayward 2000). Each time an electrode is contacted by the tongue, a complete electrical circuit is created and the contact is recorded. The EPG records can then be analysed by the researcher in order to trace the contact patterns and infer tongue movements.

The system used was WinEPG (Articulate Instruments Ltd, Edinburgh, UK). In this system, the electropalate contains eight rows of electrodes, six electrodes on the first row (the one behind the front teeth) and eight on each of the other seven rows, making a total of 62 electrodes. These electrodes are spaced between the point behind the top front teeth (where they meet the gum) and the back of the hard palate. Rows 1–4 correspond to the alveolar and post-alveolar region (rows 1–2 correspond roughly to the alveolar region while rows 3–4 to the post-alveolar region), while rows 5–8 correspond to the palatal and velar region.

2.2. Material

The material for the study consisted of four disyllabic words containing a word-initial alveolar stop; each token was a different combination of gemination (SING vs. GEM) and stress (unstressed vs. stressed) as shown in Table 1.

		unstressed	stressed
singleton	token	<τασή> [tɐ'si]	<τάμαν> [tə'mɛn]
	gloss	<i>ground sesame</i>	<i>vow</i>
geminate	token	<τταβάς> [tʰ:v'vɛs]	<ττάβλιν> [tʰ:ɐvlin]
	gloss	<i>stew</i>	<i>backgammon</i>

Table 1 The tokens used in the EPG study.

2.2.1. Carrier Phrase

The carrier phrase used was ‘Come on, tell him ____ and it’s enough’ (<Άτε, πε του ____ τζαι κανεί.> = [ˈɛtɛ pɛ tu ____ t͡ʃɛ kɛˈni]).¹ By using this phrase, the target alveolar stop would be in utterance-medial and intervocalic position. In order to obtain the target stop in utterance-initial position, the same carrier phrase was used, but without its first part preceding the token: ‘____ and it’s enough’ (<____ τζαι κανεί.> = [____ t͡ʃɛ kɛˈni]).

2.3. Speaker

The speaker was YP, a male native speaker of Cypriot Greek from Nicosia, aged 23 at the time of the test. YP reported no speech impairments.

2.4. Procedure

2.4.1. Presentation of material

The test sentences containing the tokens under investigation were presented to the subject on a PC screen, one at the time (filler sentences were also used).

The material was presented in Greek spelling (see §2.2), using unofficial conventions for representing the sounds of Cypriot Greek that do not exist in Standard Greek (cf. Armosti *et al.* this volume). For instance, the caron (ˇ) was used in order to represent post-alveolar sounds (e.g. <ď> symbolises [ʃ]).

The subject was asked to produce each test sentence five times at a normal rate of speech. Thus, 40 repetitions were produced in total (2 levels of gemination × 2 levels of stress × 2 levels of utterance position × 5 repetitions). Time was provided prior to the recording for the subject to become accustomed to the palate.

2.4.2. Recording

The EPG recording took place in the sound-treated booth of the University of Cambridge, using the WinEPG system. The palate was scanned for tongue-to-palate information regarding electrode activation at a sampling interval of 10 ms. At the same time, the audio signal was recorded at 22.05 KHz sampling rate and 16 bit sample width.

2.5. Analysis

The analysis of articulatory data was done with the Articulate Assistant software (version 1.12). The acoustic data analysis was done with the PRAAT speech processing software using annotated text files and PRAAT scripts.

2.5.1. Measurements

Both temporal and spatial properties of the target segments were measured. In particular, the properties measured were the following:

¹ High vowels in word-final position often undergo lenition or deletion in CyGr (cf. Eftychiou 2008). However, in the tokens recorded for this study, the [u] in [tu] was never deleted (something that would have resulted in unwanted concatenation of two [t] sounds).

Temporal properties:

- (i) The articulatory closing duration (Cld) of the stop. Cld was defined as the time interval from the first frame in which linguopalatal contact would occur before the consonant burst, until the first frame that full closure would be attained. In utterance-medial position, the stop was preceded by a vowel, an environment that often resulted in some amount of linguopalatal contact during the preceding vowel (as a coarticulatory effect from the previous consonant), and therefore there was no frame preceding the closing phase of the target stop for which the linguopalatal contact would be zero. In such cases, the onset of the closing phase was defined as the frame between the preceding vowel and the stop's full closure for which linguopalatal contact would be at its minimum.
- (ii) The articulatory seal duration (Sld) of the stop. Sld was defined as the period for which full closure of the stop was attained. Its onset coincided with the offset of the closing phase; the offset of Sld coincided with the acoustic burst observed in the waveform and spectrogram.
- (iii) The articulatory release duration (Rld) of the stop. Rld was defined as the time interval from the burst until the frame for which the linguopalatal contact would reach its minimum.
- (iv) The acoustic duration of the after closure time (ACT) as defined in Armosti (2011a). Here it coincides with aspiration.

Spatial properties:

- (v) The amount of contact measured at the frame with the maximum electrode activation during the seal phase of the stop. It was measured as the percentage of electrodes activated in that frame for two areas:
 - (a) the constriction area for the alveolar stop, defined as the first four rows from the front of the palate (R1–4).
 - (b) the whole palate.
- (vi) The location, size, and shape of the contact. These properties were investigated mainly by visual comparison of the frames at which maximum contact was attained. The contact patterns can provide information about the location of contact on the passive articulator, and also can be suggestive of the involvement of the active articulator (cf. Pandeli 1993, 18–34). Apart from contact patterns, the depth of constriction was taken into account in order to extrapolate tongue configurations (after Payne 2000, 217; 2006, 88; cf. also Eftychiou 2004, 69). For instance, a depth of one row located at the front of the electropalate suggests an apical articulation, while a depth of 3 of 4 rows can be interpreted as an apico-laminal or laminal articulation.

2.5.2. Statistics

Usually, in studies with many subjects, each subject is an experimental unit. In the present study there was only one subject due to the difficulty in finding subjects willing to undergo such a procedure; another equally restricting factor was the financial cost of creating artificial palates. Therefore, the experimental unit cannot be just one subject; instead, the individual repetitions served as the experimental unit, something that inevitably reduces the power of the statistical analysis (Cho and Keating 2001). Therefore, the results of the statistical analysis should not be treated as the basis of definite conclusions or generalisations.

Taking these caveats into account, six analyses of variance (ANOVA) were performed using the SPSS statistical software package. In each test, the dependent variable was one of the following: (i) the duration of the closing phase, (ii) the duration of the seal phase, (iii) the duration of the release phase, (iv) the after closure time (ACT), (v) the percentage of contact at the constriction area, and (vi) the percentage of contact for the whole palate. The two variables involving percentages were first transformed using the rationalised arcsine transformation, so as to become suitable for entering the statistical analysis (see Armosti 2010 for further particulars on this transformation method); all other variables were normalised into z-scores. The independent variables were three: (i) Gemination, with two levels (singleton vs. geminate), (ii) Stress (stressed vs. unstressed), and (iii) Position (utterance-initial vs. utterance-medial).

3. Results

3.1. Temporal parameters

3.1.1. Closing duration

The average closing duration of geminates and singletons was virtually the same (61 ms and 65 ms respectively), and was not affected by Stress. The position in the utterance was the only factor that played a significant role in the length of the closing phase of the stop, as utterance-initially the closing phase was 41 ms longer than utterance-medially [$F(1, 22) = 19.875, p < .0005$]; however, this result must be treated with some caution due to the difference in defining the beginning of the closing movement in the two positions in the utterance (see §2.5.1 above). No interactions were significant.

3.1.2. Seal duration

All three factors exhibited significant main effects on the duration of the seal phase. Geminates had longer Sld than singletons by 42 ms on average. In stressed syllables, Sld was 22 ms longer than in unstressed syllables.

factor	level	<i>M (SD)</i>	difference	significance
Gemination	SING	93 (45.7)	42	$F(1, 22) = 18.612, p < .0005$
	GEM	135 (28.6)		
Position	utterance-medial	85 (32.6)	58	$F(1, 22) = 34.446, p < .0005$
	utterance-initial	143 (28.8)		
Stress	unstressed	103 (48.9)	22	$F(1, 22) = 4.906, p = .037$
	stressed	125 (37.5)		
Gemination × Position				$F(1, 22) = 0.681, p = .418$
Gemination × Stress				$F(1, 22) = 4.984, p = .036$
Position × Stress				$F(1, 22) = 0.07, p = .793$
Gemination × Position × Stress				$F(1, 22) = 0.268, p = .61$

Table 2 Results for seal duration.

Regarding the Position factor, the Sld was on average 58 ms longer utterance-initially than utterance-medially. As shown in

Table 3, geminates had significantly longer Sld in both utterance positions—even though in utterance-initial position Sld is unperceivable.

Position	SING	GEM	difference	significance
utterance-initially	126 ms	160 ms	34 ms	$F(1, 12) = 5.19, p = .042$
utterance-medially	60 ms	111 ms	50 ms	$F(1, 10) = 19.261, p = .001$

Table 3 Comparison of geminate and singleton Sld in the two utterance positions.

The interaction between Gemination and Stress was significant, thus, it was explored further using a simple main effects analysis of the Sld within each level of the Stress factor. The results showed that in unstressed syllables geminates had significantly longer Sld by 64 ms [$F(1, 10) = 22.64, p = .001$]; geminates had longer Sld than singletons in stressed syllables, but this difference (20 ms) was non-significant.

3.1.3. Release duration

In the case of the release phase, Gemination was the only factor that showed significant main effects, with geminates having longer Rld than singletons by 37 ms on average. There was a significant interaction between Gemination and Stress: a simple main effects analysis showed that the distinction in Rld between singletons and geminates was maintained in the unstressed condition² [$F(1, 10) = 33.977, p < .0005$], but not in the stressed condition [$F(1, 12) = 2.577, p = .134$].

3.1.4. After closure time

Gemination was the only factor that showed significant main effects on ACT (as was the case with Rld), with geminates having longer ACT than singletons by 62 ms [$F(1, 22) = 326.343, p < .0005$].

3.2. Spatial parameters

3.2.1. Amount of contact

3.2.1.1 Amount of contact at the constriction area

In the case of the amount of contact at the constriction area (i.e. R1–4), no factor had significant main effects at $\alpha = .05$; however, the Gemination \times Position interaction was significant [$F(1, 22) = 5.066, p = .035$]. A simple main effects analysis showed that the difference in the amount of contact between singletons and geminates was significant only utterance-medially, with geminates activating more electrodes than singletons by 10% on average [$F(1, 10) = 10.809, p = .008$]. In utterance-initial position, the production of singletons activated all electrodes in the constriction area at the frame of maximum contact, whereas the geminate activated only 88% of electrodes; this was an unexpected finding, however, this difference was non-significant [$F(1, 12) = 1.240, p = .287$].

3.2.1.2 Amount of contact for the whole palate

The results for the amount of contact for the whole palate showed significant main effects of the Position factor only [$F(1, 22) = 6.480, p = .018$], with consonants in utterance-initial position having more linguopalatal contact (80%) than consonants in utterance-medial position (71%). This can be regarded as a strengthening effect caused by the position of the consonant in the utterance.

3.2.2. Location, size, and shape of contact

The location, size, and shape of contact are presented graphically using representative palatograms for each combination of the Gemination, Stress, and Position factors. In each case, two palatograms are presented: (i) an average palatogram of the seal phase and (ii) the palatogram at the frame of maximum contact. The palatograms for the seal phase represent the percentage of activation of each electrode over time averaged over all repetitions of the token; this percentage is indicated in the figures both numerically and by shades of grey (the darker the shade, the higher the percentage). The palatogram showing the frame of maximum contact was the one with the largest amount of electrode activation of all frames out of all repetitions of the token. Contact patterns and shapes will be analysed following Pandeli (1993) and Payne (2000; 2006).

² As the anonymous reviewer suggests, the Rld of [t] in [te'ʃi] may shorten due to the onset of approximation for the upcoming [ʃ] —whereas in [tʰ:ɐ'vɛs] the labiodental uses an independent articulation, thus not influencing the Rld of [tʰ:]. This discrepancy may be causing the significant difference in Rld between the unstressed [t] and [tʰ:].

Figure 1 Palatograms of unstressed singletons and geminates utterance-medially.

In the utterance-medial unstressed case shown in

Figure 1, geminates showed more linguopalatal contact than singletons. Regarding the location of contact, for singletons, the main constriction lay along the first two rows (with R1 showing more contact than R2) indicating a possible apical articulation; in the case of geminates, the occlusion occurred at the first four rows, something that could indicate an apico-laminal articulation. The firm contact at the two lateral columns for both singletons and geminates could correspond to a ‘cupped’ (concave) tongue configuration, a shape of contact that is compatible with the apical and apico-laminal interpretation of the contact patterns.

In the utterance-medial stressed case (

Figure 2) both singletons and geminates exhibited slightly more contact when stressed than when unstressed. The stressed singletons showed a somewhat deeper contact than the unstressed singletons, something that could be interpreted as a more laminal contribution to the articulation. Regarding any differences between singletons and geminates, the geminates showed more contact at rows R3 and R4 (as was the case in the unstressed condition). These results are very similar with the findings of Payne (2006, 90–91) regarding word-initial voiceless stops in phrase-medial position.

Figure 2 Palatograms of stressed singletons and geminates utterance-medially.

Figure 3 Palatograms of unstressed singletons and geminates utterance-initially.

The difference between the singleton and geminate palatograms in the utterance-initial unstressed case was reduced compared to the utterance-medial case, as shown in

Figure 3. Regarding the size of the contact, considerably more electrodes were activated utterance-initially than utterance-medially especially at the anterior area: for both singletons and geminates, the whole constriction area (R1–4) was completely occluded at the frame of maximum contact (cf. §3.2.1.1), while R5 showed substantial electrode activation (a finding that could be interpreted as a more laminal contribution to the articulation of the consonants in utterance-initial position). These patterns observed in the palatograms of maximum contact were reflected also in the palatograms showing mean electrode activation during the seal phase. This was especially true for the singleton, for which the frame of maximum contact was very similar with the average patterns shown in the seal phase palatogram (arguably due to the short duration of the singleton's seal phase, something that reduced contact pattern variation). In the case of the geminate, the increased length of its seal phase resulted in more variation of contact patterns both within the seal phase and across repetitions. This variation is reflected in the relatively lower average percentages of electrode activation observed in the palatogram of the average seal phase patterns for the geminate. These low percentages should not be interpreted as incomplete constriction in the case of the geminate (actually all tokens exhibited complete constriction), but rather as a reflection of contact pattern variation within and across tokens.

In the case of the utterance-initial stressed consonants, the palatograms shown in

Figure 4 revealed slightly more linguopalatal contact in terms of the size of the contact compared with their unstressed counterparts. The reduced percentage of electrode activation at the anterior area for the geminates was due to a particular repetition that showed no contact in the first two rows, i.e. the articulation was arguably purely laminal. Concerning the location of the contact, singletons and geminates were similar in showing complete occlusion along the first four rows.

Figure 4 Palatograms of stressed singletons and geminates utterance-initially.

These findings revealed a strengthening effect (i.e. more linguopalatal contact) of the Gemination, Position, and Stress factors: geminates were stronger than singletons, segments in utterance-initial position were stronger than those in utterance-medial position, and stressed segments were stronger than unstressed segments.

3.3. Gemination as a function of both Stress and Position

The comparison between geminates and singletons for each combination of the Position or the Stress factors was very revealing regarding the location and shape of the contact; this comparison would be revealing in the case of the rest of the variables also.

In the case of the utterance-medial unstressed segments, the geminate differed from the singleton with respect to three properties: (i) ACT, with geminates exhibiting 56 ms longer ACT than singletons; (ii) Sld; and (iii) Rld (in the latter two cases the difference was 67 ms).

Figure 5 Average distributions of electrode activation over time for the utterance-medial unstressed singleton and geminate.

[Note: The additional information in graphs 5–8 shows the variables for which the difference (d) between the geminate and the singleton is significant in the specific Stress and Position conditions.]

Figure 6: Average distributions of electrode activation over time for the utterance-medial stressed singleton and geminate.

A visual comparison of Figures 5 and 6 immediately reveals a lengthening effect of stress on the utterance-medial singleton (stress increased total articulatory gesture by 67%, Sld by 86%, and Rld by 58%), but not so much on the geminate (total articulatory gesture and Sld were virtually unaffected by stress; stress caused only Cld to increase by 62%). This strengthening of the singleton resulted in a small reduction of its difference from the geminate, as only two properties showed significant differences between the two segments:³(i) ACT, which was longer for the geminate; and (ii) Sld, which was longer for the geminate.

In the case of the unstressed segments in utterance-initial position (Figure 7), both the singleton and the geminate were substantially longer than their utterance-medial counterparts. The geminate remained statistically distinct from the singleton: the same three properties that differentiated it from the singleton in utterance-medial position (ACT, Rld, and Sld) kept the two unstressed segments distinct utterance-initially as well.

³ An additional property that could arguably distinguish geminates from singletons utterance-medially is the acoustic duration of the closure (CD); however, because CD was not possible to measure utterance-initially, it was excluded from the analysis of both positions.

Figure 7: Average distributions of electrode activation over time for the utterance-initial unstressed singleton and geminate.

In the utterance-initial stressed case, the two curves in Figure 8 were very similar. No articulatory property showed any significant difference between the two segments; only the acoustic variable, namely ACT, distinguished geminates from singletons, with geminates exhibiting longer ACT than singletons.

Figure 8: Average distributions of electrode activation over time for the utterance-initial stressed singleton and geminate.

4. Discussion

The present study aimed to investigate the articulatory differences between word-initial singleton and geminate alveolar stops in relation to stress and their position in the utterance. The main hypothesis was that, in utterance-initial position, where the acoustic closure cannot be perceptually detected, the articulation of the geminates would still be distinct from that of singletons. This hypothesis was partially supported by the results of the present study: while in utterance-medial position the articulatory gestures of the two segments were durationally distinct in both stress conditions, in utterance-initial position they were distinct only when unstressed. In other words, in prosodically dominant conditions (i.e. in utterance-initial position and when stressed) the oral articulation of geminates was virtually the same as that of singletons. This finding is peculiar considering that, in Italian for instance, the same prosodic conditions actually enhanced the gemination contrast (Payne 2006). However, Kraehenmann and Lahiri (2008) found that in Swiss German, like in Cypriot Greek, the articulatory difference between geminates and singletons decreased utterance-initially (but, unlike Cypriot Greek, the contrast was never articulatorily neutralised).

This articulatory neutralisation of the singleton vs. geminate contrast in stressed utterance-initial position can be accounted for in terms of the strength of the Stress and Position factors. Consonants in domain-initial position undergo strengthening of their oral articulation, as shown in studies for a number of languages, (see e.g. Cho and Keating 2001 for Korean). Cypriot Greek is no exception

regarding domain-initial strengthening (and lengthening): utterance-initial stops, when compared with utterance-medial stops, exhibited more linguopalatal contact over the whole palate, and longer Cld and Sld. Stress was a second factor that caused strengthening and lengthening effects on stops. Such effects of stress on alveolar stops were also found to occur in Italian (Payne 2006). In the present study, the presence of stress caused a lengthening of the stop's seal duration. The combination of the levels of Position and Stress can be thought to result in lengthening and strengthening of the segments in a somewhat cumulative manner.

This gradient increase in length and strength resulted in the articulatory neutralisation of the gemination contrast observed in the graphs of section 3.3, wherein the segments became articulatorily longer and stronger according to the following order of conditions: utterance-medial unstressed < utterance-medial stressed < utterance-initial unstressed < utterance-initial stressed. In the utterance-medial unstressed case, i.e. the weakest one, the difference between singletons and geminates was maximised. In the utterance-medial stressed case, the singleton lengthened more than the geminate, a fact that reduced the articulatory difference between them (especially at their release phase); however, the difference between the geminate and singleton seal duration was still significant. In the utterance-initial unstressed case, the singleton showed a substantial increase in duration and in the amount of linguopalatal contact; nevertheless, the articulatory difference between the singleton and geminate was not reduced compared with the utterance-medial unstressed case, as the geminate showed a substantial lengthening as well. In the utterance-initial stressed case, i.e. the strongest one, the geminate could not increase in length or strength any further, as approximately 350–400 ms length and 80% amount of contact over the whole palate appear to be the limits of the stop's enhancement by Stress and Position—limits which had already been reached in the utterance-initial unstressed case. The singleton had reached the 80% limit of the amount of contact in the utterance-initial unstressed case, hence it could not strengthen either, but there was room for more lengthening. Thus, the singleton in the utterance-initial stressed case reached the length limit too, and the two segments became articulatorily indistinguishable.

Despite that articulatory neutralisation, the difference between geminates and singletons could be acoustically (and perceptually) maintained in all cases, as the ACT of geminates was always longer than the ACT of singletons. Thus, even though the singleton~geminate contrast was articulatorily marked in most cases by means of oral articulations, the laryngeal articulation of the stops was the only consistent property in maintaining the contrast: after the stop's burst, the glottis was kept spread for longer in the case of the geminate than in the case of the singleton. This finding could be potentially interpreted as an indication that the contrast is not one involving gemination, but rather aspiration. However, since this neutralisation occurred in only one prosodic condition (i.e. in utterance-initial, stressed condition), while in the (admittedly less rare) utterance-medial position the gemination contrast was articulatorily maintained by means of more than one cues (unrelated to aspiration), it cannot be concluded that the contrast is one of aspiration throughout all cases. Besides, when all cues are available in the signal, the duration of the closure is too important an acoustic cue not to be considered central to the contrast (as shown in Armosti 2011a). Furthermore, in the perceptual study of Armosti (2010) it was shown that closure duration is a very important perceptual cue to CyGr gemination. Finally, aspiration as a cue is not incompatible with a gemination analysis, because, as argued by Armosti (2011b), aspiration is shown in many occasions to correlate with phonological weight.

The observation that geminates are not always distinct from singletons in terms of their oral articulation, and that the difference between the two segments is reduced in stronger combinations of Stress and Position, could be interpreted as an indication that the target oral gesture of singletons and geminates is the same, but articulatory undershoot takes place for weaker consonants (i.e. singletons, unstressed consonants, and consonants in utterance-medial position); because the oral gestures for weaker consonants are executed in less time, the contact with the palate can be incomplete, the occlusion (Sld) and release (Rld) shorter. This aspect is worth investigating in the future.

5. Conclusions

The EPG investigation of word-initial geminate and singleton alveolar stops revealed that even in utterance-initial position, where the closure is unperceivable, geminates were still articulatorily longer than singletons. However, this was true only in the unstressed case, as stress and utterance position seem to have enhancing effects on the duration and strength of the consonants.

These enhancing effects of stress and utterance position indicate that there can be some gradience in the binary geminate~singleton contrast, in the sense that the length and strength of the stops are

susceptible to these prosodic factors; a consequence of this gradience is the articulatory neutralisation of the geminate~singleton contrast under the combined influence of stress and utterance position. Nevertheless, the contrast is always preserved acoustically (and perceptually) by means of the duration of the stop's aspiration.

EARLY L1 GREEK WH-QUESTIONS: SHORT- OR LONG- DISTANCE INTERPRETATION?

Evangelia K. Asproudi

Aristotle University of Thessaloniki, Greece

evangelia.asproudi@gmail.com

ABSTRACT

This paper investigates Greek children's preference for short-/long-distance interpretation of the extracted wh-phrase in ambiguous questions. Crosslinguistic studies show that younger children resort to LD readings; older children, however, demonstrate high SD preference. To examine whether Greek children follow the same pattern, ninety 4-to-7 year-old children participated in similar comprehension tasks. The results revealed similarity to crosslinguistic findings. The younger children displayed high preference for LD interpretations, which started to give its place to SD preference as age increased. This is explained under a memory-based proposal; former proposals linking Theory of Mind and the language faculty prove to be inadequate.

Keywords: wh-questions, comprehension, short-distance, long-distance, Greek, L1

1. Introduction

The aim of this paper is to investigate the comprehension of affirmative wh-questions in Greek by typically developing children. To be more specific, what is explored is preschool-age children's distance preference in the interpretation of the raised wh-element in ambiguous questions. The main goal underlying this exploration is to see whether children's overall performance potentially reveals the operation of economy-based processing.

In order to provide answers to the above questions, reference needs to be made initially to several notions related to wh-movement, such as short- and long- distance interpretation, the Subjacency constraint and islands.

1.1 Short-/Long- Distance Wh-Movement, Subjacency and Islands

Wh-movement refers to interrogative constructions, where a wh-phrase is moved from its original position. When the wh is moved to another position within the same clause, wh-movement is known as *short-distance* (SD); when moved to a position in a different clause, wh-movement is known as *long-distance* (LD). SD and LD movement are respectively exemplified in (1)-(2) and (3)-(4) below:

(1) *Who_i does she love t_i?* (English)

(2) *Wen_i liebt sie t_i?* (German)
whom love-3SG she
'Who does she love?'

(3) *Who_i do you think she loves t_i?* (English)

(4) *Wen_i glaubst du dass sie liebt t_i?* (German)
whom think-2SG you that she love-3SG
'Who do you think she loves?'

In (1) and (2), 'who' and 'wen' move from the object position *t_i* to a fronted position within the same clause. In (3) and (4), however, the fronted wh-elements 'who' and 'wen' originate from the embedded object position *t_i* but have moved LD to the matrix periphery.

Focusing for a while longer on LD movement, central to its formation is the *Subjacency* constraint, which was initially proposed by Chomsky (1977) and reads as follows:

Subjacency Constraint:

The wh-phrase must pass successively through every intermediate SpecCP position before it reaches its final landing site. (Chomsky, 1977)

In later versions of the Minimalist Program, the Subjacency constraint and its cyclicity effects are captured directly by the notion of phase and its accompanying Phase Impenetrability Condition (Chomsky 1998, 1999).

Subjacency may be violated in the presence of *islands*, which are elements that block the LD raising of the wh-phrase to the edge of matrix CP. With regard to English, examples of islands are adverbial clauses ((5)), wh-islands ((6)), factivity ((7)) and negation ((8)):

- | | |
|--|-----------------------|
| (5) <i>Who_i did John cry [after Bill kissed *t_i]?</i> | (from Boeckx, 2008) |
| (6) <i>Why_i do you wonder whether John read the book *t_i?</i> | (from Lasnik, 1999) |
| (7) <i>When_i did you regret that you left *t_i?</i> | (from Roussou, 1992b) |
| (8) <i>Why_i don't you think we can help him *t_i?</i> | (from Rizzi, 1990) |

Let us now see how SD/LD movement and islands apply to Greek.

1.2 Wh-Movement in Greek

Similarly to English, SD and LD wh-extraction in Greek is formed by fronting the wh-phrase to the matrix left periphery. (9) and (10) below exemplify these two types of extraction:

- (9) *Pjon_i ajapai t_i?*
 whom love-3SG
 'Who does she love?'
- (10) *Pjon_i nomizis oti ajapai t_i?*
 whom think-2SG that love-3SG
 'Who do you think she loves?'

Focusing for a while longer on LD movement, it is allowed in the presence of the lexical complementiser 'oti' or 'na', as illustrated in the following examples:

- (10) *Ti_i ipes oti tha dhjivasun t_i ta pedhja?*
 what said-2SG that will read-3PL the children
 'What did you say that the children will read?'
- (11) *Ti_i ipes na dhjivasun t_i ta pedhja?*
 what said-2SG to read-3PL the children
 'What did you tell the children to read?' (from Tsimpli & Dimitrakopoulou, 2007)

As for islands, again on a par with English, adverbial clauses ((12)), wh-elements ((13)), factivity ((14)) and negation ((15)) constitute islands in Greek.

- (12) *Pjon_i efije apo to domatio [xoris na xeretisi *t_i]?* (from Tsimpli, 1998)
 whom left-3SG from the room without to say goodbye-3SG
 * 'Who did s/he leave the room without saying goodbye to?'
- (13) *Pos_i anarotjese ti eftiakse *t_i?* (from Roussou, 1992a)
 how wonder-2SG what fix-3SG
 * 'How do you wonder what s/he fixed?'
- (14) *Ti_i metanjoses pu aghorases *t_i?* (from Roussou, 1992b)
 what regret-2SG that bought-2SG
 * 'What did you regret buying?'

- (15) *Pos_i dhen fotografizis to spiti *t_i?*
 how not photograph-2SG the house
 * ‘How don’t you photograph the house?’

As illustrated in the above examples, the presence of an island blocks a LD interpretation of the raised wh-element.

Having outlined basic notions about wh-movement at a theoretical level, the next section will deal with an overview of crosslinguistic child studies on question comprehension.

2. Child Studies on Question Comprehension

As stated from start, this paper focuses on the investigation of the patterns employed by children during the comprehension of ambiguous wh-questions. Early language studies have shown that when provided with a story context that makes salient both a SD and a LD interpretation of the raised wh, the younger children most often resort to the LD reading; the SD reading is the preferred choice for the older ones. Examples of such studies are those by de Villiers et al. (1990, 2007) and by Abdulkarim et al. (1997), where, in ambiguous questions like (16) and (17) below, the tested children showed preference for a LD over a SD answer:

- (16) *Why did the boy say he took a bath?*
 because his sister asked him – SD answer
because he was dirty – LD answer
- (17) *When did the boy say he hurt himself?*
 in the evening – SD answer
in the afternoon – LD answer

This pattern of responses seems to be rather counter-intuitive. For its explanation, two related accounts have been put forward. According to de Villiers et al. (1990), younger children have not yet mastered all the subcategorization possibilities of verbs. As a result, they are not able to analyze the embedded clause as a complement of the matrix verb (e.g. of ‘say’) but most probably as the real clause in need of an answer; hence, LD interpretations of the fronted wh arise. In a more recent account, de Villiers et al. (2007) proposed that younger children lack a Point of View (PoV) feature projection from a matrix mental or communication verb; due to this lack, they cannot defer transfer of the edge feature to a later phase but can only interpret it locally within the first phase. In other words, the fronted wh-element is linked with the embedded rather than with the matrix verb.

3. The Present Study

3.1 Predictions

In view of previous research, the prediction formulated with regard to Greek children’s comprehension of ambiguous wh-questions was the following:

Prediction:

- a. Preference for LD interpretations in the younger ages
- b. Increasing preference for SD interpretations in the older ages

In other words, the comprehension preference pattern that has been attested crosslinguistically and that has been explained in terms of children’s attempt to interpret movement locally (de Villiers et al., 2007), is expected in the Greek comprehension data as well.

3.2 Participants

The study group consisted of ninety typically developing children aged 4;0 to 7;0. For the analysis of the data, these children were divided into three equivalent subgroups A, B and C. Group A included

thirty children between four and five (mean age range: 4;6), group B thirty children between five and six (mean age range: 5;5) and group C thirty children between six and seven years old (mean age range: 6;7). Group A and B children were in their first and second year in kindergarten respectively, while group C children attended the first grade in primary school.

3.3 Materials and Procedure

The children participated in a task that was designed along the principles of McDaniel et al. (1996) and Crain & Thornton (1998). The task consisted of six short stories that replicated scenarios used in similar studies in other languages (e.g. Roeper & de Villiers, 1992; Thornton & Crain, 1994; de Villiers et al., 1990). All six stories were followed by comprehension questions; with more specific reference to the test questions accompanying each story, these were wh-COMP (2 subject, 2 object, 2 adjunct) questions that were ambiguous between a SD and a LD interpretation, with both choices being grammatical. Given the story context each time, all interpretations were made salient, while there was no issue of bound variable possibility. Finally, to preclude a bias for one interpretation over the other, care was taken to deliver all test questions in as neutral intonation as possible.

Here is a sample of the short stories presented as well as of the test questions set.

1st story (English translation)

The dog has a ball. The cat and the rabbit have to climb up a wall to see who has the ball. The cat tries first: she takes a ladder and tries to climb up the wall but eventually falls down. Then the rabbit tries: she uses the same ladder, climbs up the wall and sees the dog. Then she says: “I can see who has the ball! The dog has it and he is holding it with his legs!”

Experimenter’s question: *Pjos_{ij} t_i emathe oti t_j ehi ti bala?* (subject-COMP)

‘Who_i t_i found out that she has the ball?’ – SD reading

‘Who_i did she find out t_i to have the ball?’ – LD reading

Target answer: *to kuneli* ‘the rabbit’ – SD reading

o skilos ‘the dog’ – LD reading

2nd story (English translation)

The child is eating something. The cat and the rabbit cannot see because the child is in the room. So, they try to find a way to see from the window. The rabbit tries first, but she does not manage to see because the window is too high. Then the cat tries. She jumps very high and says: “I can see what the child is eating! She is eating a tomato and she is eating it with great delight!”

Experimenter’s question: *I jata ti_{ij} idhe t_i oti troi t_j?* (object-COMP)¹

‘Who_i did the cat see t_i to be eating?’ – SD reading

‘What_j did the cat see that the child was eating t_j?’ – LD reading

Target answer: *to pedaki* (‘the little child’) – SD reading

domata (‘tomato’) – LD reading

3rd story (English translation)

Alex likes climbing up trees. One afternoon, he tries to climb up a tree but he fell down. Then he went back home; he took a shower and saw a big bruise on his arm. In the evening he said to his dad: “I got hurt in the afternoon”.

Experimenter’s question: *Pote_{ij} ipe t_i o Alexis ston patera tu oti htipise t_j?* (adjunct-COMP)

‘When_i did Alex say t_i to his dad that he got hurt?’ – SD reading

‘When_i did Alex say to his dad that he got hurt t_j?’ – LD reading

Target answer: *to vradi* (‘in the evening’) – SD reading

to apojevma (‘in the afternoon’) – LD reading

Each child was tested separately in a room next to their classroom. The duration of this task was about 25 minutes. After an explanation of the procedure to follow, each of the six stories was acted out

¹ Unlike subject and adjunct, in object questions the wh-element did not appear sentence-initially. The reason is that in argument questions the aim was to locate the wh-element as close as possible to the two extractions sites available (SD-LD). Thus, in object questions the subject appeared sentence-initially, so as not to intervene later on. Adjunct extraction sites were more easily traceable, so this restriction was not considered for adjunct questions.

with props in front of the child or presented through pictures to her. At the end of each story, the comprehension question was posited, with the aim to see which reading – SD or LD – the child would prefer. In case the child did not respond to a certain test question, this question was repeated once; if no answer was elicited, the procedure proceeded with the presentation of the next story and its accompanying question.

4. Results and Discussion

The main prediction in this paper is that, during the comprehension of ambiguous questions, the younger children will mostly resort to LD readings, while SD readings will start to become more preferred with an increase in age. This prediction is largely confirmed by the obtained results, as illustrated in the following figure:

Figure 1 Short-Distance Preference per Extraction Site in Question Comprehension

In subject and adjunct questions, SD interpretations ranged at similar levels - especially within groups B and C - and became increasingly higher with age. As for object questions, SD rates were extremely low in the two younger groups and null in the oldest group, thus contrasting with the corresponding rates in subject and adjunct questions. These observations are also supported statistically. A two-way mixed ANOVA was performed on the results: question type (3) \times group (3). The main within-subject effects of question type [$F(2,174)=48.973$, $p=.000$] and of question type by group interaction [$F(4,174)=3.433$, $p=.01$] were both significant. In addition, the main between-subject effect of group was also found to be significant [$F(2,87)=6.940$, $p=.002$]. Within all three groups, pairwise comparisons revealed significant differences in terms of SD interpretations between object and subject (A: $p=.005$, B: $p=.000$, C: $p=.000$) as well as between object and adjunct questions ($p=.000$), but not between subject and adjunct ones. Between groups, SD reading rates increased significantly between B and C in subject questions (A-C: $p=.001$, B-C: $p=.053$) and gradually across groups in adjunct questions (A-C: $p=.035$). On the contrary, in object questions no significantly different comparisons were attested since SD reading rates remained at very low levels throughout. On the whole, subject questions seem to pattern together with adjunct questions, both of which come in contradistinction with object questions.

As reported in section 2, evidence of children's initial preference for LD over SD interpretations in globally ambiguous questions has also been observed in other early languages, like early English and early Arabic (de Villiers et al., 1990; Abdulkarim et al., 1997; de Villiers et al., 2007). Subject and

adjunct early Greek questions pattern together with wh-interrogatives in other early languages, whereas object ones do not. This ‘deviation’ may be attributed to lexical reasons and, more concretely, to properties of the object-extracted wh-phrase ‘ti’. That is, all object questions employed the wh-word ‘ti’, which carries the [-animacy] feature; on hearing ‘ti’, then, children would immediately build a structural representation of the input string that relates ‘ti’ with the LD inanimate referent rather than with the SD animate one. On this ground, no firm conclusion can be drawn about distance preference in object questions, but only about subject and adjunct questions.

Overall, then, object questions aside, the results of the present study showed that SD interpretation rates were generally low but increased with age. As explained in section 2, the two proposals that have been put forward crosslinguistically in order to account for this rather counter-intuitive pattern were related to an incomplete inventory of verb subcategorization properties (de Villiers et al., 1990) or to a lack of a PoV feature projection (de Villiers et al., 2007). However, these explanations do not seem to be very satisfactory. Given that the PoV feature is assumed to project from mental and communication verbs, it is clear that it is directly related to the Theory of Mind. The Theory of Mind has been found to interact with the faculty of language (e.g. Happé, 1995; Garfield et al., 2001; Brent et al., 2004; Hughes et al., 2005); still, as revealed through studies on mental/language disorders (e.g. autism, Asperger syndrome, agrammatic aphasia), the Theory of Mind and the faculty of language are independent from each other and may stand in a relationship of double dissociation (e.g. Happé, 1991; Smith & Tsimpli, 1995; Tsimpli & Smith, 1998; Varley & Siegal, 2000; Smith et al., 2003). On the basis of all this, it can be argued that the encoding of a PoV feature projection in grammar would need independent justification that would subsequently lead to reduction of the explanatory power of language. Thus, the PoV account is rejected in the present paper over an alternative proposal that may probably be linked to memory considerations.

Specifically, younger children’s LD interpretation preference may be attributed to the fact that due to their limited working memory capacity, children ignore the matrix verb as parenthetical and consider the embedded clause as the one and single question needing an answer. These working memory limitations may reside largely at a semantic level. That is, the greater semantic saliency associated with the embedded activity predicate (e.g. ‘troo’ [=‘eat’]) compared to the matrix perception/communication predicate (‘matheno’ [=‘learn’], ‘vlepo’ [=‘see’], ‘leo’ [=‘tell’]) may trigger the treatment of the matrix verb as parenthetical and of the embedded one as the true question. Therefore, although interpretation is in this sense completed locally, children essentially answer LD to the initial wh-element. Older children with an increased memory will not ignore the matrix verb on semantic saliency grounds and, therefore, they may prefer to link the extracted wh-element with it in an attempt to establish the shortest wh-chain possible (cf. Theophanopoulou-Kontou, 1991).

5. Conclusions

In conclusion, this paper has dealt with the L1 comprehension of ambiguous wh-interrogatives. The results revealed that increase in age goes hand in hand with increase in children’s preference for SD readings of the extracted wh-phrase². As has been explained in the previous section, even younger children’s more prominent resort to LD readings constitutes a local processing strategy for them. On the basis of these observations, more generalised conclusions can be drawn about the fundamental question shaped at the beginning.

It is evident that, on a par with their peers crosslinguistically, Greek children aim to a maximum degree of locality during the comprehension of wh-interrogatives. Preference for locality attests, in turn, for preference for economy-based processing. What is essential to underline here is that this economy-based processing is not triggered exclusively on syntactic grounds. As suggested by the distance preference pattern in object questions and by the role of verb predicate semantic saliency in subject and adjunct questions, semantic factors also seem to affect processing. Thus Jakubowicz’s (2005) Derivational Complexity Hypothesis, according to which less complex derivations are correctly spelled out at the PF interface before more complex ones during language development, can be seriously challenged. Children’s processing ability may have problems not at the level of form (as suggested by Jakubowicz’s Derivational Complexity Hypothesis) but at the level of meaning integration. In other words, economy-based processing in children seems to be constrained by a combination of syntactic and semantic factors.

² Remember that object questions do not follow a similar pattern. Yet, they are excluded from the above generalization on the assumption that their divergent behaviour is largely due to the inherent properties of the questioned wh-element and not to its extraction site.

PRODUCTION OF THE GREEK RHOTIC IN INITIAL AND INTERVOCALIC POSITION: AN ACOUSTIC AND ELECTROPALATOGRAPHIC STUDY

Mary Baltazani

University of Ioannina, Greece

Katerina Nicolaidis

Aristotle University of Thessaloniki, Greece

knicol@enl.auth.gr

ABSTRACT

This paper investigates /r/ production in phrase initial, word initial and intervocalic position. Rhotic production was found to include a vocoid preceding the constriction phase in phrase initial position. Duration, formants, place and degree of constriction, and variability due to position, context, and speaker were examined. Typically the vocoid was longer in duration than the constriction, with formants similar to the transconsonantal vowel, suggesting the production of a vocalic gesture upon which the rhotic is superimposed. Electropalatographic data show an alveolar rhotic, although there is variation in place due to context and variability from fully constricted to more open articulations.

Keywords: Rhotic, prosodic position, phrase-initial, word-initial, intervocalic, Greek, duration, electropalatography

1. Introduction

Rhotics exhibit considerable phonetic variety across languages. Variation has been reported as a function of context, position, speech rate and dialect (Lindau 1985; Inouye 1995; Ladefoged & Maddieson 1996; Recasens & Pallarès 1999; Recasens & Espinosa 2007).

In the Greek literature there is no consensus on the nature of the rhotic. Older phonological descriptions classify it as a trill (Φιλίππακη-Warburton 1992; Nespor 1996). More recent studies describe it as a tap when it is found in intervocalic position (Nicolaidis 2001; Baltazani 2005, 2009) or in initial and intervocalic position (Arvaniti 1999). Experimental studies have reported considerable variability in its acoustic and articulatory characteristics. Both a tap and an approximant realization have been observed (Nicolaidis 2001; Baltazani 2005, 2009) and its place of articulation has been reported to vary across alveolar, retracted alveolar, and postalveolar positions (Nicolaidis 2001; Nicolaidis & Baltazani 2011, (submitted)). Further contextual variation has been detected. While tap productions are typical in initial or intervocalic position, the presence of a vocoid has been documented between the /r/ and the consonant in /Cr/ and /rC/ sequences (Baltazani 2005, 2009; Nicolaidis & Baltazani 2011, (submitted)). Such a realization has also been found in clusters in several Spanish dialects, in Catalan, as well as in French, Finnish, Romanian, Hungarian, and Hamburg German (Navarro Tomás 1918; Rochette 1973; Harms 1976; Jannedy 1994; Bradley & Schmeiser 2003; Bradley 2004; Colantoni & Steele 2005; Recasens & Espinosa 2007; Vago & Gósy 2007; Savu 2012). The production of this more complex articulation in Greek clusters with /r/, which involves a constriction and a vocalic phase, has received different interpretations. Arvaniti (2007) claims that this articulation indicates trill production in clusters while Baltazani (2005, 2009) interprets these findings as evidence for a tap production which involves a vowel-like transition between the consonant and the rhotic. Electropalatographic data reported in Nicolaidis & Baltazani (2011, (submitted)) show that there is typically one constriction present during rhotic production in clusters and sequences in Greek providing evidence of a tap articulation.

The research presented in this paper is part of a bigger project examining /r/ in several prosodic positions including its realisation in /Cr/ and /rC/ sequences (Nicolaidis & Baltazani 2011, (submitted)). The current study investigates the production of /r/ in (a) phrase initial, (b) word initial but phrase medial, and (c) word medial intervocalic position aiming to clarify the effect of prosodic position on the realization of the rhotic. An important question addressed is whether a vocoid is attested in any of these prosodic positions and if so how frequently it is present. We explore the structure of this element by looking into the vocoid's range of duration compared to the constriction phase of the /r/.

Moreover, we consider the vocoid's formant structure to uncover possible effects of the vocalic context. In addition, we examine the effect of context and prosodic position on its articulation. Finally, we attempt to shed more light on the characterization of this segment as a tap vs. a trill.

The remainder of this paper is organized as follows: Section 2 explains our methodology, section 3 presents the acoustic and articulatory results and section 4 offers a discussion of the results.

2. Methodology

2.1 Speech material and speakers

Real words containing an /rV/ sequence (V=/i, e, a, o, u/)¹ in three prosodic positions were recorded: phrase initial (/##rV/), word initial within a phrase (/V1#rV2/) and intervocalic (/V1rV2/). In phrase initial position the test word was uttered in isolation. All other test words were embedded in the carrier phrase [I 'leksɪ _ 'ine a'pli] 'The word _ is simple'. The rhotic found in the /V1#rV2/ condition was preceded by /i/, i.e. the last vowel of the word 'leksɪ' of the carrier phrase, while for the /V1rV2/ condition, V1 was consistently an /a/, resulting in the sequence /arV/. All test words were 2-3 syllables long, stressed on the /rV/ syllable and repeated five times at a comfortable speaking rate by three female (MM, KN, RP) and two male (AT, TP) adult Greek speakers. In total, 375 words were recorded (5 Vs x 3 positions x 5 repetitions x 5 speakers).

2.2. Recording procedure

Simultaneous acoustic and electropalatographic (EPG) data were recorded using the British EPG system marketed by Articulate Instruments. In addition, a separate recording of acoustic data was made on a digital recorder (Marantz PMD 660) with a Røde NT1-A cardioid condenser microphone.

Acoustic data were analysed using PRAAT. We measured the durations of the rhotic constriction phase and of the vocoid, as well as the F1 and F2 formants of the vocoid (in word initial position) and of the V1, V2 vowels to detect possible environment influences on the vocoid. The onset of the constriction phase—together with the onset of the voicebar—was marked at the offset of silence, V1 or vocoid, depending on prosodic position. The offset of constriction was marked at the beginning of the formants for V2 (Figure 1). The beginning and end of the vocoid in phrase initial position was marked at the onset and offset of its formant structure respectively (Figure 2).

Figure 1 Segmentation criteria for word initial /r/: onset of the constriction was marked at the offset of V1 and offset of constriction at the beginning of the formants for V2. The example sentence here is [I 'leksɪ 'rima 'ine a'pli] (the underlined part is displayed only)

Figure 2 The beginning and end of the vocoid in phrase initial position was marked at the onset and offset of its formant structure respectively. The example here is the word [ˈrema] uttered in isolation

¹ Throughout the paper the /r/ symbol is used for the Greek rhotic for practical reasons. Similarly, the vowels are transcribed as /i, e, a, o, u/. For a description of the quality of the Greek vowels, see Arvaniti (1999, 2007).

Electropalatographic data were analysed using the Articulate Assistant software (version 1.18) which accompanies the British EPG system used in this study. The artificial palate of this system has 62 electrodes on its surface which detect lingual contact with the palate in continuous speech. Electrodes are distributed in eight rows according to particular anatomical landmarks (Figure 3). The front four rows correspond to the alveolar zone and the back four rows to the palatal zone. The alveolar zone is subdivided to the alveolar and postalveolar regions (rows 1 to 2 and 3 to 4 respectively) (Gibbon & Nicolaidis 1999; Recasens et al 1993).

Figure 3 The artificial palate used for the British EPG system marketed by Articulate instruments (left). Schematic representation of electrodes and division of electrodes into zones and subzones (right)

For the articulatory analysis, the first EPG frame of maximum contact/constriction in the four front rows was identified for each rhotic (Figure 4). The four front rows were selected because the place of articulation of the rhotic always occurred in the alveolar zone. The frame of maximum contact typically coincided with the frame of maximum constriction during the rhotic. In the few instances that it did not, the frame of maximum constriction in the alveolar zone was annotated. Following data annotation, the percentage frequency of electrode activation of the entire palate over five repetitions was calculated for the rhotic in each test word (see, e.g., Figure 5).

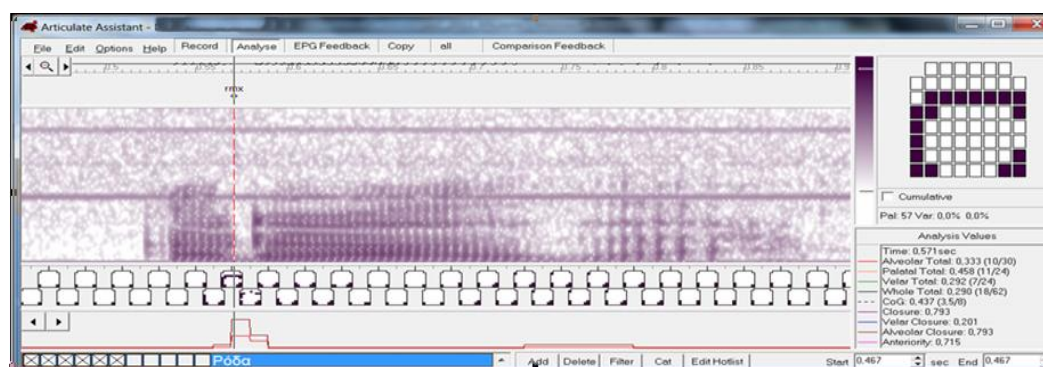

Figure 4 Screen display from Articulate Assistant showing acoustic waveform, spectrogram, EPG palatograms and contact totals display (whole and alveolar totals) for the rhotic in the word [roða] produced in phrase initial position by the female speaker MM. The annotation line corresponds to the first frame of maximum contact/constriction in the alveolar zone. The corresponding palatogram is shown at the top right of the display

3. Results

3.1 Acoustic analysis

The analysis of the acoustic data (and of the articulatory data, section 3.2) clearly showed that the Greek rhotic is produced as a tap and not a trill. In phrase initial position, i.e. when it is preceded by silence and is unaffected by a preceding sound, its production is typically realized with an initial vocoid followed by a single constriction phase (Figures 2, 4). In word initial position within a phrase and in word-medial position, the typical realization is again a tap with a single constriction of short duration. In these positions, the existence of a vocoid was not as easy to determine because of the presence of V1 before the tap: in word initial, phrase medial position the /r/ initial word was preceded by a vowel-

ending word and obviously in intervocalic position the rhotic was placed between two vowels. There is, however, acoustic evidence suggesting the presence of a vocoid even in these positions. A number of tokens in both prosodic positions showed abrupt amplitude and formant changes during V1 like those shown in Figure 5. The top two panels of Figure 5 show the same sequence, [i#ru], which is part of the words /'leksi 'rumi/ 'word rum' pronounced by the same male speaker, TP, in two different repetitions. Note that the panels show different degrees of disjunction between the two words (no disjunction in the top, clear separation in the bottom), something which permits the detection of the vocoid in the acoustic signal with different degrees of clarity.

The top panel shows an increase in amplitude and a discontinuity in formants approximately in the middle of V1. These acoustic events suggest that the vocalic stretch that we labeled 'V1' changes in quality halfway through its duration from the unstressed final [i] of the word /'leksi/ to the vocoid, which is similar in amplitude and formants to the stressed [u] of the word /'rumi/. On the other hand, in the middle panel a pause occurs after the [i], which in turn is followed by a vocoid before the rhotic constriction. Interestingly, the vocalic stretch before the rhotic constriction in the top panel is much longer (over 100ms) than what is expected for an unstressed [i], while in the middle panel [i] lasts less than 60ms. Thus, the middle panel corroborates our analysis of the acoustic events in the top panel.

The bottom panel of Figure 5 shows the sequence [i#re], part of the words /'leksi 'rema/ 'word stream', where the last 1/3 of V1 also shows an abrupt change in amplitude, becoming as loud as the stressed V2. In other words, the acoustic events described above suggest the presence of a vocoid which is adjacent to V1 and to some degree overlaps with it. Although a more in-depth analysis and precise methodology for identifying this vocoid interval in a consistent manner is needed—an issue which we leave open for future investigation—the preliminary evidence provided above indicates that this vocalic gesture is an essential part of the rhotic itself (cf. Blecua 2001 for Peninsular Spanish).

Figure 5 Abrupt formant and intensity discontinuities in V1. The top two panels show the same sequence, [i#ru], which is part of the words /'leksi 'rumi/ 'word rum' pronounced by the same speaker in two different repetitions (please see text for details). The bottom panel shows the sequence [i#re] in /'leksi'rema/ 'word stream'. The last 1/3 of V1 also shows an abrupt change in amplitude, becoming as loud as the stressed V2.

The following two sections present the duration and formants results of the acoustic analysis.

3.1.1 Duration results

The duration of the rhotic was compared across the three prosodic conditions in this experiment. Figure 6 presents the results for the constriction durations across all positions and the vocoid duration in phrase initial position. It should be pointed out that the vocoid duration was only measured in phrase initial position (see section 3.1 for an explanation). The number at the top of each column in Figure 6 gives the average duration in ms.

The results showed that the constriction is longest in word initial within phrase position. No difference was found in the constriction duration between the phrase initial and intervocalic positions². Note, furthermore, that the differences in the duration of the constriction across the three prosodic positions are small, with only a 8.5ms difference between the average longest and shortest duration. When comparing these constriction durations to those in /Cr/ and /rC/ sequences reported in Nicolaidis & Baltazani (2011, (submitted)), the duration in word initial position is comparable to its duration in /rC/ sequences (mean 32ms), while the phrase initial and intervocalic position durations are comparable to the average duration in /Cr/ clusters (24ms).

The vocoid, on the other hand, is considerably longer, being more than double in length compared to the constriction phase in phrase initial position. The vocoid in phrase initial position in this experiment was also found to be longer than in /rC/ and /Cr/ sequences reported in Nicolaidis & Baltazani (2011, (submitted)). These comparisons indicate that the different prosodic positions exert an asymmetric influence on the two components of the rhotic. One possible reason for such asymmetries relates to the articulatory nature of these components. The tap, which has been described as a short ballistic gesture in the literature (Lindau 1985; Ladefoged & Maddieson 1996; Recasens & Pallarès 1999; Recasens & Espinosa 2007), is not as free to lengthen as the vocoid. A comparison across more prosodic positions, including data from /Cr/ and /rC/ sequences, which is discussed in more detail in Baltazani & Nicolaidis (forthcoming), can shed more light on questions like these.

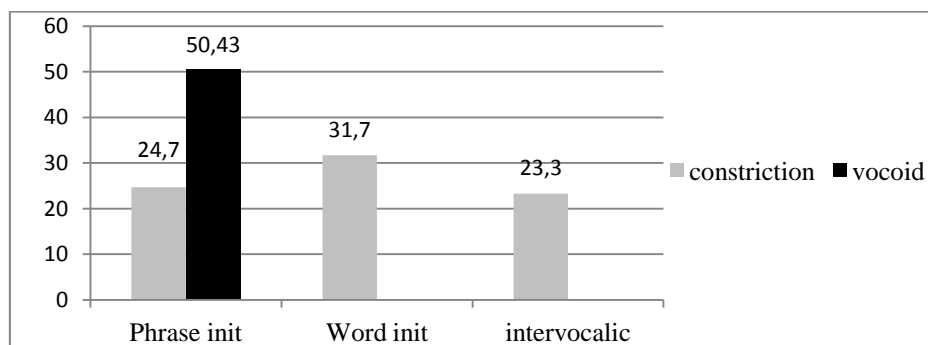

Figure 6 Duration comparison across the three prosodic conditions

3.1.2 Formant results

Measurements of F1 and F2 for the vocoid and the transconsonantal vowel V2, in phrase initial position showed that the formant values of the vocoid in phrase initial position are similar to those of the transconsonantal nuclear vowel, with a tendency to be more centralized than V2.

The four panels in Figure 7 present comparisons of the average formant values for V2 (black line) and the vocoid (grey line) in the F1XF2 vowel space. Centralization tendencies are clearly evident for all speakers for the vocoid.

² Tables with details on durations for all conditions broken down by speaker are given in Appendix B.

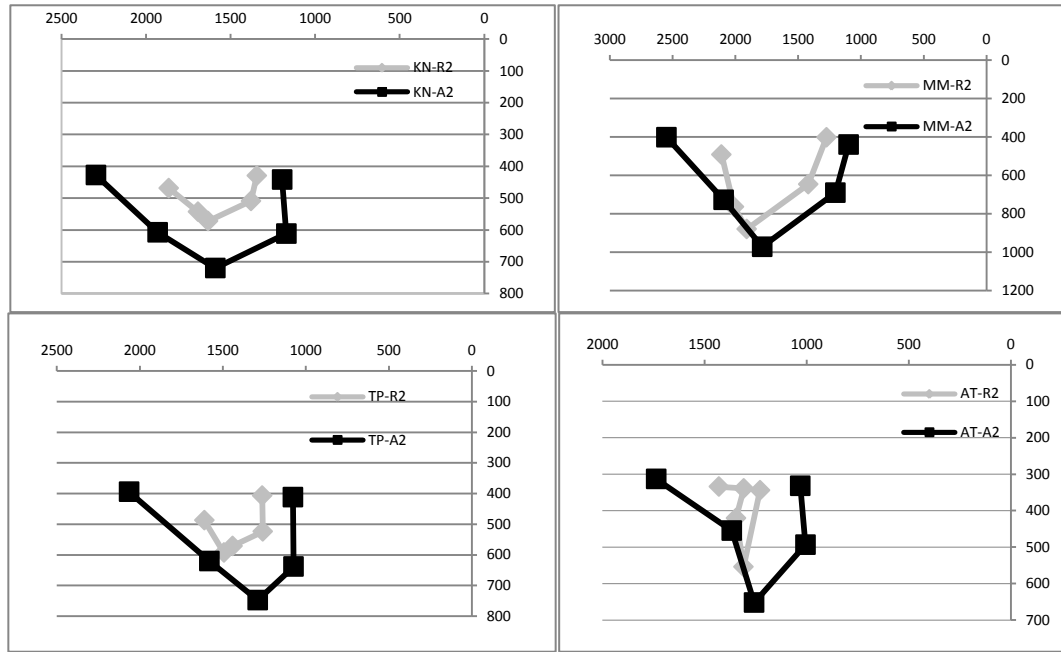

Figure 7 Comparison of V2 (black line) and vocoid (grey line) formant values for four speakers

Variability in the realization of both the vocoid and V2 was found as a function of speaker and of vowel. Figure 8 presents the Euclidean distance between the vocoid and V2 across speakers and vowels. This distance is the square root of the sum of the squares of the difference between the vowel formant frequencies³ and bigger numbers indicate greater distance between the vocoid and V2 formants, hence a greater amount of centralization for the vocoid. The vowel /i/ shows the greatest amount of centralization overall and the vowel /u/ the smallest, but all vowels show variability across speakers. Among speakers, RP shows the smallest amount of centralization for the back vowels /o, u/ and the greatest amount for /e/, but otherwise the most consistent trend is variation.

Figure 8 The Euclidean distance between the vocoid and V2 across speakers and vowels

3.2 Articulatory data

The articulatory analysis, consistently with the acoustic analysis, showed that the typical realization of the rhotic involves a single constriction across all three prosodic conditions. The EPG data showed that the articulation of the rhotic varied as a function of the vocalic context, the prosodic position, and the speaker. Variation was evident both in place of articulation and degree of constriction. Figure 9 shows

³ $ED = \sqrt{((F1V1 - F1V2)^2 + (F2V1 - F2V2)^2)}$.

an example of variation in place of articulation due to the following vocalic context. More advanced production is evident in the front vowel contexts /i/, e/. The palatograms show that in the environment of /i/ and /e/ there is a front alveolar production present with contact in the first and/or second row of electrodes. In the remaining vowel contexts, there is a retraction of the place of articulation with presence of contact in the third row of electrodes especially in the context of /o/, u/. The data thus provide evidence of a retracted alveolar or advanced postalveolar articulation in the back vowel contexts.

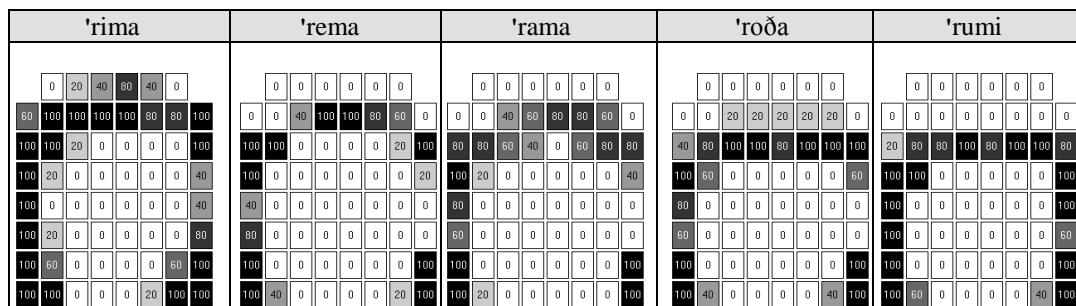

Figure 9 EPG palatograms displaying percentage frequency of electrode activation over five repetitions during the production of the /r/ in phrase initial position in the words (from left to right) /'rima, 'rema, 'rama, 'roða, 'rumi/ by the female speaker MM

In addition, the EPG data showed variation in the degree of constriction of the rhotic. Constriction varied from complete contact, usually across one row of electrodes, to incomplete constriction. Tokens with incomplete constriction ranged from very constricted to very open articulations. An example of complete and incomplete constriction can be seen in Figure 10a, b. In 10b, the very open articulation and the presence of formants throughout the constriction phase of the rhotic indicate the production of an approximant.

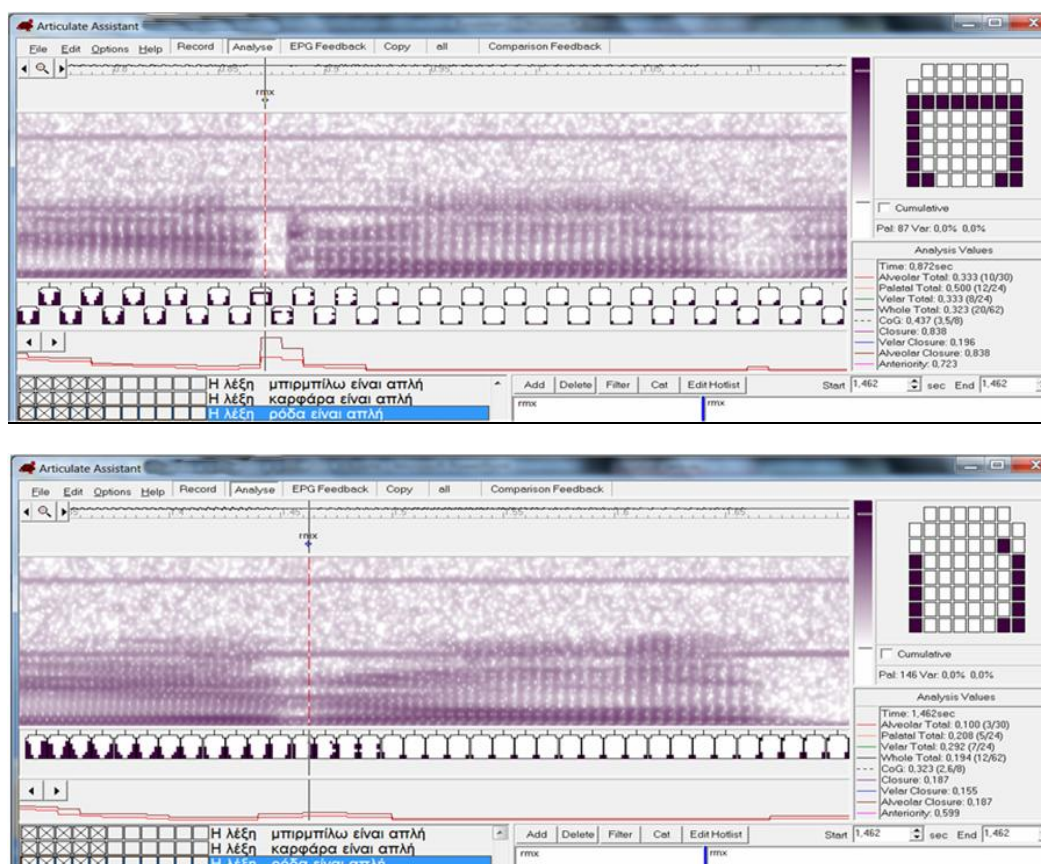

Figure 10 (a, b) Acoustic and electropalatographic data for the rhotic in the word ['roða] in word initial within phrase position. In (a) the rhotic is produced as a tap with complete constriction; in (b) there is incomplete constriction and further acoustic evidence of approximant production

Evidence of an effect of prosodic position on the degree of constriction was found in the data. In particular, more open articulations were observed for the rhotic in word initial within a phrase position compared to the other prosodic positions. A comparison of the data in Figures 9 and 11 for the rhotic in phrase initial and word initial position shows such variation in the degree of constriction.

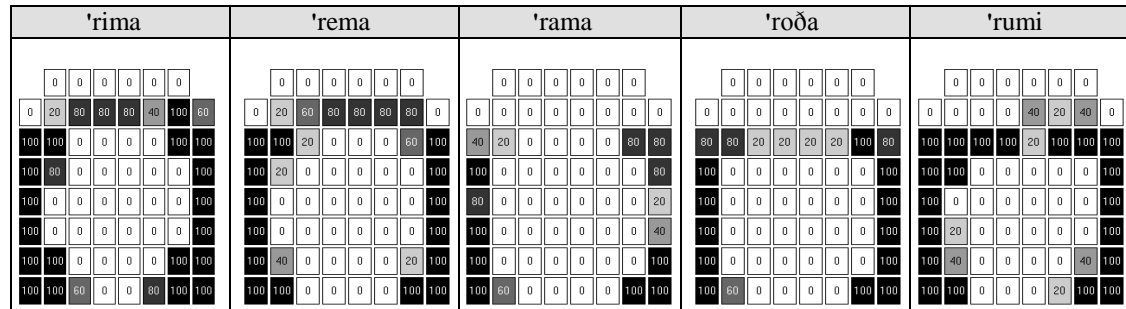

Figure 11 EPG palatograms displaying percentage frequency of electrode activation over five repetitions during the production of the /r/ in word initial within a phrase position in the words (from left to right) /'rima, 'rema, 'rama, 'roða, 'rumi/ by the female speaker MM

Variation in degree of contact, place of articulation and degree of constriction was also evident as a function of speaker. Both within and across speaker variation was observed. Figure 12 presents data from two speakers illustrating such differences in place and degree of constriction. Speaker TP shows overall more advanced and more constricted productions compared to AT. Differences in the amount of contact in the alveolar and palatal zones are also evident.

Figure 12 EPG palatograms displaying percentage frequency of electrode activation over five repetitions during the production of the /r/ in phrase initial position in the words (from left to right) /'rima, 'rema, 'rama, 'roða, 'rumi/ for speakers TP (top) and AT (bottom)

The analysis showed that a substantial number of rhotics, 236 out of 375 tokens (63%), were produced with incomplete constriction (Table 1). Both the prosodic position and the speaker influenced production. In particular, more tokens were produced with incomplete closure when the rhotic was in word initial position within a phrase. Speakers KN, AT and RP show considerably more instances of open productions compared to MM and TP; over 80% of tokens for AT and RP and 70% for KN had incomplete closure.

	KN	AT	RP	MM	TP
<i>phrase initial</i>	14	21	21	7	8
<i>word initial</i>	23	25	22	17	11
<i>word medial</i>	18	17	21	8	3
Total	55	63	64	32	22

Table 1 Number of rhotics produced with incomplete constriction in the different prosodic positions by the five speakers

Finally, ten tokens of trill production were found for speaker RP in phrase initial position. Figure 13 illustrates the production of the trill with acoustic and articulatory evidence of two constriction phases and vocoid intervals. The cursor on the spectrogram corresponds to the second constriction phase which is produced with incomplete constriction in the alveolar zone (see palatogram on the top right).

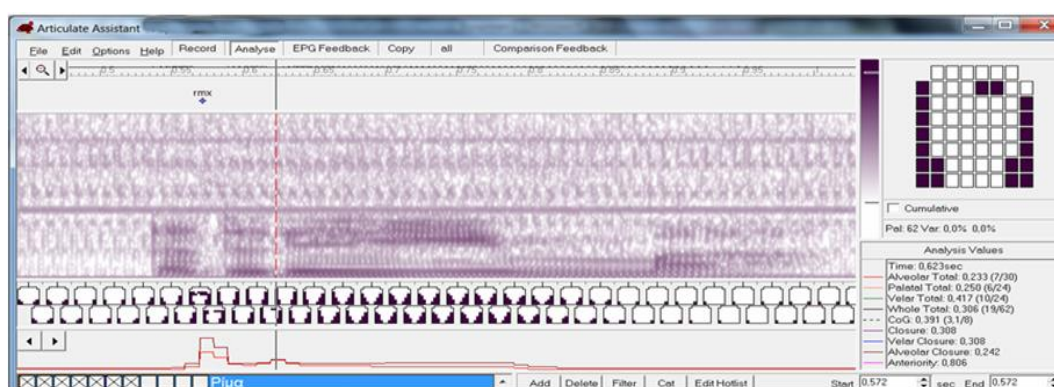

Figure 13 Acoustic and electropalatographic data for the rhotic in the word [rima] in phrase initial position produced by the female speaker RP. Trill production of the rhotic is illustrated

4. Discussion

The acoustic and articulatory data has shown that there is typically just one constriction present during the production of the rhotic, providing clear evidence for a tap rather than a trill in phrase initial, word initial and word medial position. It should be noted that there were a few tokens of trill production in phrase initial position by one speaker. The duration of the constriction phase was short ranging from 23 to 31 ms, similarly to previous findings from several languages (Lindau 1985; Recasens 1991; Recasens & Espinosa 2007). Such extreme brevity of the tap stems from a ballistic gesture whereby the tongue tip is thrown up against the alveolar ridge (cf. Ladefoged 1993: 168).

In addition to the constriction phase, a vocoid was also found in phrase initial position. Such a vocoid has been documented previously to occur in consonantal clusters or sequences with /r/ in several languages (see section 1). Evidence of its presence in phrase initial position suggests that this vocoid is an inherent part of the articulation of the rhotic which is necessary for the upcoming ballistic movement to take place (cf. Romero 1996 and Blecua 2001 for the rhotic in /Cr/ and rC sequences). Some first indications that this vocoid may be present in word initial within a phrase and word medial position, where the rhotic is flanked by vowels, was also provided. Such instances need to be further investigated but provide preliminary evidence that the rhotic is superimposed on a rhotic-specific vowel-to-vowel gesture (cf. Öhman 1966).

The quality of the vocoid depends on the nuclear vowel of the syllable with /r/. In particular, the vocoid shows similar but somewhat centralized frequencies compared to the nuclear vowel. Similar results were obtained in Nicolaidis & Baltazani (submitted) for /rC/ sequences where the vocoid had somewhat more centralized formant values than V1, the homosyllabic vowel in nuclear position. The similarity between the vocoid and the vowel on the other side of the tap constriction, especially for /Cr/ and /rC/ sequences, has been documented for other languages as well, for example, in several Spanish dialects, Catalan, Romanian, and Hungarian (Navarro Tomás 1918; Bradley & Schmeiser 2003; Bradley 2004; Colantoni & Steele 2005; Recasens & Espinosa 2007; Vago & Gósy 2007; Savu 2012). The fact that a similar structure for the tap has been found for phrase initial position in our data, in an environment that does not involve a second consonant, further indicates that the vocoid is part of the

articulation of the rhotic, with the short tap constriction being embedded on a longer vocalic gesture, which it momentarily interrupts (cf. Öhman 1966).

The duration differences found between the vocoid and the constriction further corroborate our interpretation of the rhotic as a tap. Standard descriptions of trills mention equal durations for the vocalic and consonantal intervals of the trill, something which is in accord with their articulatory descriptions as an involuntary trilling which is set in motion by aerodynamic forces (e.g. Recasens 1991). The duration data for phrase initial /r/ show that the vocoid is on average twice as long as the constriction, clear evidence that the Greek rhotic is not a trill.

In addition, variation in the duration of the rhotic (both for the constriction and vocoid intervals) and the formant structure of the vocoid were found due to speaker and prosodic position with an added influence of vowel quality on the formant structure of the vocoid. Smaller differences were found for the constriction than the vocoid, since the articulatory nature of the extremely short ballistic movement necessary for the production of the tap do not leave much freedom for lengthening.

The electropalatographic data provided evidence of variability in the place of articulation of the rhotic and in the degree of constriction as a function of the context, the prosodic position and the speaker. With reference to the place characteristics of the rhotic, it was consistently produced in the alveolar zone but its production ranged from front alveolar to retracted alveolar or postalveolar (cf. Nicolaidis 2001; Nicolaidis & Baltazani 2011, (submitted)). More fronted productions in the environment of the front vowels /i, e/ and more retracted productions in the back vowel environments were evident. Such contextual effects suggest that the tongue tip/blade adapts to the gestures for neighbouring phonetic segments during the production of the rhotic. Similar findings have been reported for taps in other languages (e.g. Recasens & Pallarès 1999; Recasens 1991).

In addition, the degree of constriction ranged from complete contact across one of more rows in the alveolar zone to very open articulations. Evidence that 63% of the tokens were produced with incomplete contact indicated that the rhotic frequently involves approximation of the lingual gesture to the palate (cf. Nicolaidis 2001; Nicolaidis & Baltazani 2011, (submitted)). For these tokens, presence of formant structure during the constriction phase provided further evidence of approximant production (cf. Baltazani 2005, 2009). Across the three prosodic positions examined, more open productions in word initial position within a phrase were found, compared to intervocalic and phrase initial positions, providing evidence of influence of prosodic position on the articulation of the rhotic. Interestingly, these results suggest that the factor regulating the amount of contact in the three prosodic positions is not solely the strength of the boundary since, for instance, more tokens with complete constriction were found intervocalically than in word initial position. This finding together with the variation reported for the duration of the constriction phase and the vocoid in the different prosodic positions (including the /Cr/ and /rC/ sequences examined in Nicolaidis & Baltazani 2011, (submitted)) suggest that more investigation is necessary to account for the spatial and temporal variation present during the production of the rhotic as a function of prosodic position.

Finally, the speaker was also an important source of variation with substantial differences in place of articulation (more fronted productions for some speakers and more retracted for others), constriction degree (more open productions vs more constricted productions) and overall amount of contact.

ON SOME PHONETIC AND PHONOLOGICAL PROPERTIES OF THE GREEK GLIDE

Mary Baltazani

Nina Topintzi

Universität Leipzig, Germany
nina.topintzi@uni-leipzig.de

ABSTRACT

This paper presents preliminary results of two experiments investigating acoustic characteristics of the glide in several environments in Greek. We show that the phonological claims of Topintzi&Baltazani (to appear) regarding the phonemic status of both /i/ and the glide /j/ as well as of the existence of two separate palatalization processes (simple vs. extreme) are phonetically supported. In the first experiment, different degrees of curvature in the F2 trajectory and different transition rates distinguish /Vi/ hiatuses from /Vj/ diphthongs. The second experiment supports the distinction between simple and extreme palatalization as signaled by durational and formant differences.

Keywords: Glide, diphthong, hiatus, palatalization, onglide transition, duration, formant trajectory, transition rates

1. Introduction and Aims

Considerable literature has been devoted to understanding the perplexing phonological distribution of the Greek glide because of its propensity to act both as an independent phoneme and as an allophone of /i/ (Mirambel 1959; Koutsoudas 1962; Householder 1964; Kazazis 1968; Setatos 1974; Warburton 1976; Nyman 1981; Malavakis 1984; Nikolopoulos 1985; Deligiorgis 1987; Malikouti-Drachman&Drachman 1990; Rytting 2005; Topintzi&Baltazani (to appear)). All previous analyses, however, have been relying on an impressionistic characterization of this segment, since an analysis of its phonetic nature is still lacking¹.

In this paper, we attempt to understand the nature of the glide by examining its acoustic properties in several environments, invoke new questions and provide insights to segments related to it, such as the palatals². Standard Modern Greek has a palatal glide³, whose phonetic realization depends on the phonetic environment, its position within the syllable, and, according to the acoustic results in this paper, on the morphophonological environment. Roughly speaking, postconsonantly it emerges as a fricative (voiced [j] or voiceless [ç]), but if there's a /l/ or /n/ directly preceding it, it surfaces as palatal lateral [ɭ] or nasal respectively [ɳ]. Postvocally however, it has been impressionistically claimed to surface as a true approximant [j] (references), a fact that we phonetically establish for the first time in the present work. Note that whenever our focus is on phonology and not phonetics, we will be using the shorthand GLIDE or /J/ to refer to all the possible realizations of this segment. The paper is structured as follows: Section 2 addresses phonological issues of the glide and poses questions that the phonetic investigation in §3 and §4 seeks to answer. In particular, §2.1 examines phonological diagnostics that differentiate the glide from the front high vowel. §2.2 summarizes a recent phonological analysis of the postconsonantal glide/onglide (Topintzi&Baltazani (to appear)), also presently adopted. Section 3 presents the first experiment –dealing with the phonetics of postvocalic glides and section 4 presents the second experiment

¹There is only a brief mention in Arvaniti (1999, 2007), where the glide is described as a palatal fricative.

²Note that in the articulatory analysis of Nicolaidis (2003) these segments are described as palatalized velars.

³ This is not true for other dialects. For example, Baltazani&Topintzi (2010) show that Northwestern Greek dialects also exhibit the glide [w].

examining postconsonantal glides. Finally, in section 5 we offer a discussion on the implications for the analysis and understanding of the glide.

2. (Morpho)phonology of the glide

2.1 Glide vs. /i/ diagnostics

Identification of a /V+highvocoid/ sequence as involving an autosegmental [Vj] or a heterosyllabic [V.i] string is not straightforward for native Greek speakers. We offer several diagnostics, however, which facilitate the task. Notably, the fact that [i] and [j] are distinct from one another in the same environment corroborates the idea that both these sounds are phonemic in the language. Diagnostics A-C are useful for the detection of postvocalic glides, while Diagnostic D for the detection of postconsonantal ones. To begin with, consider how the trisyllabic window constraint of Greek stress (restricting the appearance of stress on the final three syllables of a word) enlightens us on glide identification. Forms in (1a) must contain a glide, since otherwise stress would be on the pre-antepenult, which is illicit. For the examples in (1b) though this issue is irrelevant, given that either syllabification respects the trisyllabic window.

(1)	Diagnostic A: Trisyllabic stress window		
	<i>Antepenult</i>	<i>Pre-antepenult</i>	<i>Gloss</i>
(a)	yáj.ða.ros ⁴	*yá.i.ða.ros	“donkey”
	xáj.ðe.ma	*xá.i.ðe.ma	“caressing”
(b)	ne.ráj.ða	ne.rá.i.ða	“fairy”
	psa.ro.káj.ko	psa.ro.ká.i.ko	“fishing boat”

Tokens of the (1b) type thus warrant a different diagnostic. This comes from the so-called enclitic stress (ES) that appears on words normally stressed on the antepenult when followed by a possessive clitic, *mu* “my”, *su* “your”, etc. In such instances, a second, enclitic, stress emerges as illustrated below. We abstract away from the issue of which stress is considered primary and which secondary.

(2)	Diagnostic B: Enclitic stress		
	<i>Enclitic stress</i>	<i>No enclitic stress</i>	<i>Gloss</i>
(a)	án.θro.póz mu	*án.θro.poz mu	“my person”
(b)	psa.ro.ká.i.kó mu	*psa.ro.káj.ko mu	“my fishing boat”
(c)	*ne.rá.i.ða mu	ne.ráj.ða mu	“my fairy”

(2a) exemplifies normal application of ES without the presence of any vocoid. The antepenultimately-stressed [án.θro.pos] receives an additional stress on the ultima once the clitic attaches to it. (2b) shows application of ES which is only possible if we assume that the /V+highvocoid/ sequence is heterosyllabic. (2c) on the other hand demonstrates that an offglide has to be assumed since no-ES appears.

The third diagnostic also employs stress. Under certain types of prefixation, e.g. with [paʎo-] ‘old-’, [θeo-] ‘god-’ or [pan-] ‘all’, among others, stress shifts from its original position and retracts to the antepenult. Once more, if these prefixes attach to words containing vocalic sequences in the right position, we can spot the difference between /i/ and /j/.

(3) Diagnostic C: prefixation		
(a)	[kaíci] “small boat”	pa.ʎo.ká.i.ko *pa.ʎó.kaj.ko “old small boat”
(b)	[xaiváni] ⁵ “jackass”	pa.ʎo.xáj.va.no *pa.ʎo.xa.í.va.no “rotten jackass”

⁴Throughout the paper the /r/ symbol is used for the Greek rhotic instead of the tap for practical reasons. Similarly, the vowels are transcribed as /i, e, a, o, u/. For a description of the quality of the Greek vowels, see Arvaniti (1999, 2007).

⁵ We use the Greek grapheme *iota* *i* here to indicate that either [i] or [j] would be compatible with this example. Of course, once we apply our diagnostics, its true nature becomes clear.

The final diagnostic to consider here applies to postconsonantal positions, thus it differentiates between /i/ and the onglide. As becomes evident through the near-minimal pairs of (4), /i/ and /J/ are contrastive.

- (4) **Diagnostic D:** minimal pairs
- | | | | |
|----------|-----------------|---------|--------------------|
| á.ði.a | “permission” | á.ðja | “empty-FEM-NOM-SG” |
| sci.á.zo | “shade” | scá.zo | “scare” |
| pi.é.ste | “press-2PL-IMP” | pç'este | “drink-2PL-IMP” |
| ó.pi.o | “opium” | ó.pço | “whichever” |

The picture though is not as yet complete. While /i/ and /J/ indeed contrast, there are also cases where they alternate with one another, indicating an allophonic relationship too. A well-known and highly productive alternation of this type arises in the paradigm of neuter nouns ending in *-i*.

- (5) [i]~[j] alternations
- | | | | |
|----------|----------|-----------|-----------|
| pó.ði | “foot” | pó.ðja | “feet” |
| ðo.ká.ri | “girder” | ðo.kár.ja | “girders” |
| má.ti | “eye” | má.tça | “eyes” |

2.2 Summary of Topintzi&Baltazani (to appear)

To account for the observation that /i/-/J/ can both contrast as well as alternate, we adopt a recent analysis in Topintzi&Baltazani(to appear), whereby we suggest that both /i/ and /J/ are phonemes that can neutralize in specific contexts due to morphophonological pressure. In particular, it is claimed that word-internal hiatus is generally admitted in the language (IDENT-IO[±voc] >> *VV⁶). This means that an underlying glide and an underlying high front vowel normally surface intact, as for instance, in [xaj.vá.ni] “jackass” vs. [la.i.kós] “public”. The contrast however is neutralized under the influence of the paradigmatic constraint requiring an identical number of syllables throughout a paradigm (OP-Faith-σ#) and the ranking in (7).

- (6) OP-Faith-σ#: Words in a paradigm have an identical number of syllables (cf. Bat-El 2008)
- (7) *i-J alternation vs. lack thereof*
OP-Faith-σ# >> IDENT-IO[±voc] >> *VV

This explains why hiatus is tolerated throughout the paradigm of nouns ending in <-io>, e.g. ðomátio - ðomatíu “room-NOM.SG.” vs. “room-GEN.SG”, but is resolved in the nouns in <-i>, e.g. ðemáti - ðematçi “sheaf-NOM.SG.” vs. “sheaf-GEN.SG”. While in the former case the number of syllables across the paradigm remains constant and thus hiatus is permitted⁷, the only way to keep the number of syllables identical in the latter example (and simultaneously conform to the language’s phonotactics) is through i-J alternation. For details and the technical aspects of the analysis, see Topintzi&Baltazani (to appear).

The analysis of the glide has welcome extensions for the understanding of Greek palatals in general. For starters, consider the fact that the examples [pó.ði - pó.ðja] “foot - feet” and [ní.çi - ní.ça] “nail - nails” are morphophonologically comparable and thus ought to receive the same account. In addition, notice that the palatal in the NOM.SG. [ní.çi] corresponds to palatalization as velar fronting before a front vowel, whereas the palatal in the NOM.PL. [ní.ça] is more complex, since it should also involve gliding, in analogy to [pó.ðja].

We thus propose that there are two types of phonological palatalization in Greek. The former is termed *simple palatalization* and occurs in underived environments, as in [cípos] “garden”. It can be schematized

⁶ We adopt Nevins’ and Chitoran’s (2008) view that the feature that distinguishes vowels from glides is [+/- vocalic]. Vowels are [+voc], glides are [-voc]. Glides thus can pattern with vowels because they share [-cons] and can pattern with consonants because they share [-voc].

⁷ OP-Faith-σ# would also be satisfied if the paradigm wholly contained a glide, e.g. [ðomatço - ðomatçi], but this would cause unnecessary IDENT-IO [±voc] violations. Of course, one also predicts such paradigms stemming from words with input glides. This prediction is borne out, e.g. [psóno - psónu] “shopping”.

as *Velar+i,e* → *Palatal+i,e*. The second type comes under the name of *extreme palatalization* (cf. Bateman 2007 and references therein) and involves the palatalization of a consonant (either a velar obstruent or *n, l*) before a glide, which subsequently gets to be absorbed by the newly created palatal. Thus, schematically: *Velar/Alveolar+J+V* → *Palatal+V*. We additionally claim that extreme palatalization not only occurs in derived environments, cf. [ní.ça], but also in underived ones, e.g. [çóni] “snow”. Consequently, palatals in Greek – apart from /j/, that is – are always derived and originate from either plain velars (simple palatalization) or from velars + J (extreme palatalization). Notably this analysis accounts for the seemingly phonemic nature of palatals in minimal pairs like [xóni] “sticks in” vs. [çóni] “snow”, [náta] “there they are” vs. [náta] “youth”, among others.

2.3 Experimental questions

The preceding phonological discussion generates a number of interesting questions about the phonetic character of the glide, which, to our knowledge, have not been investigated in Greek. This paper forms part of a bigger project which addresses these issues testing the /i/ vs. /j/ phonemic hypothesis and the distinction among the three palatalization processes outlined above. Here we present results from a subset of the speakers that were recorded and of the measurements that have been planned (see below for details). In §3 we present findings regarding /V+high front vocoid/ sequences (henceforth postvocalic environments) and in §4 /palatal C+V/ sequences (postconsonantal environments).

3. Experiment 1 – postvocalic environment

In postvocalic environments, it is not always clear whether /V+high front vocoid/ sequences are hiatuses (vowel-vowel) or diphthongs (vowel-glide). The diagnostic tests (section 2.1) are moot in words with final or penultimate stress after the /V+high front vocoid/ sequence. As a result of this limitation, we decided to inspect sequences where our diagnostic tests do distinguish between /V+i/ and /V+j/ for acoustic differences between them.

3.1 Methodology

We report preliminary results from four female speakers, AM, SL, VM and PM, who were recorded in a quiet room with a head-mounted microphone directly into the computer, reading the material presented to them in random order on slides on the computer screen, at a comfortable speed. After manual segmentation of the target segments (see below for criteria), durations of palatal segments and their surrounding vocoids (/i/ and /j/), as well as formants of vocoids were automatically obtained using Praat scripts (Boersma & Weenink 2007).

20 words were used (Table 1) in two vocoid (/j/ or /i/), two stress (stressed/unstressed preceding V) and two focus (focussed/unfocussed word) conditions. Table 1 presents the materials: the first two columns show the 10 words that contained a [V+i] sequence and the last two columns the 10 words with a [V+j]⁸ sequence (5 with a stressed and 5 with an unstressed V). The target words were embedded in a sentence (a) without focus [leo ___ ksana] “I say ___ again” and (b) with focus [ipa ___, oxi ___] “I said x, not y”, where y is a word contrasting with x. The resulting corpus contained 160 tokens (4 speakers X 20 words X 2 focus conditions).

⁸No consistent terms are used in the literature for these sequences. From here on, we call tautosyllabic sequences ‘diphthongs’ and heterosyllabic ones ‘hiatuses’.

Stressed [i]	Unstressed [i]	Stressed [j]	Unstressed [j]
táizma “feeding”	aθinaikós “athenian”	xájdema “caressing”	majmú “monkey”
psarokáiko “fishing boat”	mosaikó “mosaic”	nerájða “fairy”	kajmáci “cream”
áipnos “sleepless”	laikós “folksy”	májna “mynah”	majdanós “parsley”
máios “May”	aploikós “simplistic”	korójðo “sucker”	xajváni “jackass”
vúizma “buzzing”	plainí “side”	yájðaros “donkey”	xajmalí “amulet”

Table 1 Material for Experiment 1

According to the cross-linguistic literature the most consistent index for the glide/i distinction is the F2 transition trajectory (Gay 1968; Ren 1986; Aguilar 1999). Fast transitions are interpreted as a diphthong whereas slow ones are interpreted as a hiatus (cf. Chitoran 2002). F2 values for [i] and [j] were automatically measured through a Praat script at 0%, 25%, 50%, 75%, 100% points and the range of the F2 curvature was determined by the difference between the maximum frequency value and the values at the beginning and end points. The rate of F2 change was calculated by dividing the start-max distance in frequency by the corresponding distance in time, and the durations of [i] were compared to those of [j] across stress and focus conditions. Examples illustrating the criteria for segmenting the vowel from the following [j/i] are provided in 3.2.

3.2 Segmentation

The onset and offset of the vocalic sequence were marked at the onset/offset of periodicity next to a stop closure, burst, or noise, or next to frication period, and as the beginning/end of larger period or greater amplitude next to nasals or liquids.

The [V+i] sequences (Figure 1) were the most straightforward to segment, as they typically had two steady states, one for each vowel. In the sequence /ai/ from the word /plainí/ “side” produced by speaker AM, the boundary between the vowel and the following /i/ is marked at the end of the steady state for /a/. The entire transition from the steady state of /a/ to the steady state of /i/ has been included in /i/ so that the curvature in the F2 trajectory could be compared across experimental conditions. Notice also that there is a change in amplitude at the F2 transition onset, a common occurrence in our data. We followed this method for all hiatus tokens.

Figure 1 Speaker AM, /plainí/ “side”. There is a clear steady state in both V1 and /i/ in this example and the F2 transition onset from /a/ to /i/ is clear. There is also a change in amplitude at the F2 transition onset

The [V+j] sequences were frequently much more difficult to segment, as the typical structure for diphthongs showed a continuous transition from V to [j] and no steady state was easily discernible, as Figure 2 illustrates. The sequence shown is [aj] from the word [majdanós] “parsley”. We followed criteria used for Chinese diphthongs in Ren (1986) and Romanian in Chitoran (2002), to define the transition onset from V to the [j] as the lowest F2 value at the end of V, before a rise of at least 20 Hz. The change in amplitude in the waveform at the F2 transition onset is visible in this example, as well.

Figure 2 Speaker AM, [majdanós] “parsley”. This example illustrates tokens that were difficult to segment since no clear steady state is discernible

3.3 Results

The results did not show duration differences between hiatuses and diphthongs; they did, however, show differences in F2 transition values. Duration results are presented first.

The duration of [i] and [j] showed variability across speakers, segments and focus conditions. Figure 3 shows representative results of the average durations across tokens for two out of the four speakers analysed, AM (top) and PM (bottom). Stressed [i] and [j] were longer than their unstressed counterpart. Apart from that, no other general trend can be observed to differentiate hiatuses from diphthongs. Notice for example that while focussed and stressed [i] and [j] are longer than unfocussed ones for speaker AM, the same does not hold for speaker PM. Moreover, focussed unstressed [j] is longer than [i] for AM, but the opposite holds for PM. These results, although tentative since they are based on a small number of speakers, suggest that duration cannot safely differentiate between hiatuses and diphthongs.

Figure 3 Duration of [i] and [j] in vocalic sequences across stress and focus conditions shown for two of the four speakers, namely AM (top), PM (bottom)

Evidence of a difference between a [Vi] hiatus and a [Vj] diphthong was evident, however, in the F2 comparisons, where, a greater F2 curvature was observed for [j], resulting from a greater difference between the maximum F2 value and the start and end values, as shown in Figure 4. Comparable results were found for the other two speakers. In addition to the greater F2 curvature, much less variability is exhibited in the beginning, max and end point values for [j] than for [i], suggesting less articulatory freedom for the former. Stress and focus did not show a consistent effect on F2.

Figure 4 F2 trajectories for hiatus and diphthong for VM (top) AM (bottom)

The rate of F2 change results (Figure 5) revealed that on average, across experimental conditions, transitions from V1 into [j] were faster than those from V1 to [i]. Similar results have been reported in Chitoran (2002). Figure 5 shows representative results for two out of the four speakers analysed, namely, AM (left) and VM (right). Although the general trend for all four speakers analyzed was faster transitions for diphthongs, it was not consistent across all experimental conditions, as can be observed in focus-stressed condition for AM and unstressed condition for VM, and therefore our conclusions are tentative, awaiting confirmation from the analysis of the four additional speakers recorded.

Figure 5 F2 transition rates for hiatuses and diphthongs for AM (left) and VM (right)

4. Experiment 2 – postconsonantal environment

Postconsonantal sequences were investigated for phonetic differences among segments participating in different palatalization processes:

- Simple palatalization: Velar⁹ + /i, e/ → Palatal + /i, e/, that is, a process where the palatalization target does not absorb the palatalization trigger, i.e. *afront*, non-low V, cf. /kípos/ → [cípos] “garden”, /kerós/ → [cerós]
- Extreme palatalization whereby the triggering high glide is absorbed by the resulting palatal consonant:
 - Velar/Alveolar + J+V → Palatal+V in morphologically underived environments, e.g. [çóni] “snow”
 - Velar/Alveolar + J+V → Palatal+V in morphologically derived environments, e.g. [níç+a] “nails”, with a morphological boundary between the palatal and the following vowel, in this case the neuter plural marker

4.1 Methodology

The materials were recorded together with those for postvocalic sequences (section 3). Six categories of target words, one per segment [ç, j, c, ʝ, ɲ, ʎ] were tested across three conditions: Simple pal. (SP), extreme derived (EDP) and extreme underived (EUP).

	SP	EDP	EUP
ç	níç <i>i</i> “nail”	níç <i>a</i> “nails”	çonás “wintry weather”
j	zíj <i>i</i> “weight”	zíj <i>a</i> “weights”	jojó “yo-yo”
c	lúc <i>i</i> “gully”	lúc <i>a</i> “gullies”	cotís “coward”
ʝ	cúj <i>i</i> “jar”	cúj <i>a</i> “jars”	julékas “(name)”
n/ɲ	pçón <i>i</i> “pawn”	pçón <i>a</i> “pawns”	ɲonó “brain”
ʎ	vól <i>i</i> “bullet”	vól <i>a</i> “bullets”	ʎodári “lion”

Table 2 Materials for postconsonantal sequences

⁹ Palatalization does not directly affect labials or coronal obstruents, e.g. [pçáto] “plate”, [ðódja], where both the obstruent and the following glide surface, although it should be pointed out that the glide is strengthened to a fricative. This is unsurprising, since palatalization typically applies to a subset of consonants (cf. Bateman 2007).

Several measurements have been planned (F2 of C, V and C-to-V transitions, duration of C, V and C-to-V transitions, intensity, and center of gravity of consonantal release); in this paper we are reporting on duration of the palatal segments and on F2 of the transitions from the palatal into the following vowel: NíChiosáin & Padgett (2012) report higher F2 for vowels next to palatalized consonants, which predicts differences in F2 for the C-to-V transitions among SP, EDP and EUP, if these three processes involve different degrees of trigger absorption.

4.2 Segmentation

Similar segmentation criteria to those in Experiment 1 were used (see 3.2). Figure 6 shows a representative example, the sequence [ja] contained in the word [cúja] “jars”, produced by speaker PM (N.B: to aid relevant measurements, [j] in the annotation marks transition from the palatal to the beginning of the steady state of the following V). The left boundaries of palatal segments were marked at the end of formant structure of the vowel preceding them and their right boundaries either at the onset of noise or the onset of formant structure of the following vowel. For a full description of this example, see section 4.3.

Figure 6 Two instances of extreme palatalization in the word *cúja*, “jars” (underived in [cú]; derived in [ja])

4.3 Results

Our results showed that the three palatalization processes (SP, EDP, EUP) differ in the acoustic parameters of their phonetic realization examined in this paper. Before proceeding with the duration and formant results we first discuss three representative examples.

Figure 6 nicely illustrates many characteristic events in extreme palatalization both at morpheme boundaries, i.e. the sequence [ja], as well as in underived environments, i.e. in [cú]. The effect of the palatal consonants is visible on the vowels on either side of each consonant, showing a high F2 on glide/offglide (whose movement is also visible during the noise of the palatal /c/). Notice however that the downward F2 movement after the /j/ starts from a much higher point, (2345 Hz), compared to that after /c/, (1751 Hz), and similar to the point (2387 Hz) where the downward F2 movement starts during the noise of /c/. Moreover, the rate of F2 change from /c/ to /u/ is much faster than from /j/ to /a/, 8.19 and 14.65 Hz/ms respectively. The transition in /u/ is steeper and much shorter in duration: 26ms in /u/, 57ms in /a/. These phonetic differences were consistently found in our data and suggest that in EDP there is a smaller degree of absorption of the triggering [j] than in EUP. For some of the speakers there were no transitions at all in EUP environments like in Figure 7, which shows the sequence [çɔ] in the word [çonás], something that was never observed in EDP environments (see 4.3.1).

Figure 7 Extreme palatalization in underived environments in the sequence [çɔ] in the word [çopás] “wintry weather”, speaker AM. There are no transitions from the palatal consonant into [ɔ]

Finally, Figure 8 presents an example of simple palatalization. The figure shows the word [cúji], “jar” (cf. Fig 6). The [i] in the sequence [ji] is, as expected, much longer than the [j] transition in the previous examples.

Figure 8 Simple palatalization in the sequence [ji] in the word [cúji], “jar”

In the following two sections, we present duration and formant results.

4.3.1 Duration

Variation in the duration for consonants, vowels and speakers was evident across conditions in our data. Starting with consonant duration, the analysis showed no consistent trend other than variability for the palatal consonants and the low/back vowels following them. In addition to these segments, we also compared the duration of the glide-like transition from the palatal consonant to the following low or back vowel (Figure 9). The six panels in Figure 9 show durations of the glide transition in EDP environments (black) and EUP environments (striped), for [ç, j, c, ʝ, ɲ/n, ʎ/l] in order from top left to bottom right. In order to appreciate the transition length, these durations are also compared with the duration of the full vowel [i] which follows the palatal consonants in SP environments. On average the transition duration in EDP environments (33.25 ms) is almost 50% that of a full vowel [i] in SP (56.75ms) and almost double that of the transition in EUP environments (18.25 ms). Moreover the maximum transition duration in EDP environments is on average 75% the duration of the vowel [i] in SP, in other words, this transition is quite substantial in duration.

The difference in duration between the transitions in EDP and EUP environments is evident in Figure 9. More concretely, the transition in EDP environments was longer than that in EUP ones in all but one environment (for speaker PM after the consonant [j]). For some speakers and palatal segments (e.g. the top

left panel) there was no [j] transition at all evident in extreme palatalization in underived environments. Moreover, the transition in EDP is longer than the full segment [i] in simple palatalization, as can be seen for speaker AM in the panels for j, n/n, ʌ/l and speaker PM in the panel for n/n. These results offer evidence in support of our phonological analysis of the different palatalization processes.

Figure 9 Transition durations across palatalization conditions.SP (grey), EDP (black) and EUP(striped), are shown for [ç, j, c, j, n/n, ʌ/l] in order from top left to bottom right

4.3.2 Formants

More evidence for the differences among palatalization conditions is provided by the formant analysis. In order to make comparisons among the three palatalization processes, we obtained the F1 and F2 values at a point 5ms into the vowel after the palatal consonant (henceforth *transition point*) in all three palatalization conditions, so that the transition from the consonant into the vowel can be captured; any consistent differences in the quality of this transition point, combined with the duration differences reported above, could arguably be ascribed to different degrees of absorption of the palatalizing trigger by the preceding consonant. Figure 10 shows the position of the transition point in the F1XF2 space for each of the three conditions across the different consonantal environments. EDP (black) and EUP (grey) values are compared to each other and also to the corresponding values for [i] in SP¹⁰ (white) so that the position of this transition point can be appreciated in relation to the position of the vowel [i]. To begin with, the space covered by the points in each condition is clearly separated and also the position of the transition points for both EDP and EUP are further back and lower in the F1XF2 space than that for SP, which is expected since the quality of these points is also influenced by the upcoming back and low vowels.

Moreover, the position of the transition point in simple palatalization is much less variable than those in EDP and EUP. Finally, the position of the transition point for EDP is more variable across segments than that for EUP. This last result in combination with the duration results can be tentatively taken as evidence

¹⁰ Values for this point after alveolar segments [l,n] are not shown because they do not participate in simple palatalization.

of the different absorption degree of the palatalization trigger in these processes: the longer duration of the transition in EDP combined with the greater stability of the position of the transition point in the F1XF2 space could be understood as less absorption of the palatalizing trigger, compared to the shorter transition duration and more variable position of the transition point for EUP.

Figure 10 The position of the transition point in the F1XF2 space for each of the three conditions (EDP in black, EUP in grey and SP in white) across the different consonantal environments (see text for details)

5. Discussion

The analysis exposed some phonetic differences between /i/ and /j/ both in post vocalic and in post consonantal environments, giving preliminary support to our claim that these are two separate phonemes in the Greek system. Highlighting the results, the first experiment revealed that the distinction between [V.i] hiatuses and [Vj] sequences is conveyed through a greater curvature in the F2 trajectory for postvocalic [j] than for [i], realized through a longer F2 range for [j] with faster transition rates, a result which has also been reported in Chitoran (2002) for Romanian. No duration differences were detected between hiatuses and diphthongs. More speakers need to be analysed before a safe conclusion can be reached, however such a result should not be surprising, given the difficulty of native speakers to consistently distinguish hiatuses from diphthongs. Another question which needs to be explored, not addressed in this paper, is the position occupied by [j] in [Vj] sequences. We have been calling these sequences ‘diphthongs’ throughout but it is not clear whether they share the nucleus of the syllable with the vowel preceding them or whether their position is more peripheral, in the coda.

Turning to postconsonantal environments, our investigation provided preliminary evidence for a phonetic distinction predicted by our phonological analysis, according to which, simple palatalization, extreme derived palatalization and extreme underived palatalization have different triggers, different targets and different acoustic outcomes. Simple palatalization is triggered by (non-low) vowels, while extreme by the (high) glide; simple palatalization targets only velar consonants, while both

velars (/k, g, x, ɣ/) and alveolars¹¹ (/n, l/) can be extreme palatalization targets; the triggers are left intact after simple palatalization, while they are absorbed after extreme palatalization. The distinction among these processes was signalled both by duration and by formant differences, which we tentatively interpret to suggest that the realization of the glide depends on the phonetic environment, its position within the syllable, and on the morphophonological environment.

Specifically, the transition from the palatal consonant to the following vowel in EDP environments was typically shorter in duration than its counterpart in EUP and also the position of the transition point for EDP was more variable across segments than that for EUP. This last result in combination with the duration results can be tentatively taken as evidence of the different absorption degree of the palatalization trigger in these processes: the longer duration of the transition in EDP combined with the greater stability of the position of the transition point in the F1XF2 space could be understood as less absorption of the palatalizing trigger, compared to the shorter transition duration and more variable position of the transition point for EUP. This conclusion is further supported by the fact that for some of the speakers and tokens there was no transition at all observed in EUP environments (see Figure 7), while a transition was always present in EDP environments. The phonetic differences described above suggest a possible divergence in the articulation among types of palatals which should be further investigated. Since our results here are based on a limited amount of data and a small subset of the acoustic analyses that we have planned, they need to be viewed with caution, and the trends they are revealing must await confirmation from our fuller analysis.

ABSTRACT

This paper deals with the application of corpus analysis to Greek law texts in order to illustrate their stylometric profile. Due to some vagueness or rigidity elements, these texts are often criticised for constituting an opaque “legalistic” language (Tiersma 1999: 139-41). For the purposes of this study we designed a Greek Legal Corpus which we then juxtaposed to the Hellenic National Corpus¹. Using criteria, such as lexical “richness”, word and sentence length, and part-of-speech frequencies, we look for linguistic features which may affect the precision and comprehensibility of the legal language (Bhatia 2010).

Keywords: corpus processing, stylometry, text classification, legal language, statistical analysis, POS tagging

1. Introduction

The general aim of this research is to study the possibilities of applying corpus analysis to legal texts. We focus especially on the language of Greek legislation and its stylometric profile. After classifying some general properties and lexico-grammatical features of the laws, we create and process a corpus of Greek law texts. Before referring to the process and findings, some useful distinctions should be drawn.

1.1 Definitions

Many terms are used when referring to legal discourse, depending on both the scientific aspect and the corresponding legal system. In this paper, we adapt the following distinctions:

Forensic texts: According to Olsson (2004: 5) any text or item of spoken or written language is potentially a forensic text, provided it is somehow implicated in a legal or criminal context. In this respect, even a parking ticket could become a forensic text. Therefore, the term “forensic” has a much wider sense than what we are interested in.

Language of the Law: As Gibbons suggests (2003: 15) “the language of the law can be broadly divided into two major areas – the codified and mostly written language of legislation and other legal documents, such as contracts [...] and the more spoken, interactive and dynamic language of legal processes [...]”.

Legal language: the formal, formulaic, rigid, “legalistic” language of legal documents, such as statutes, court decisions, contracts, wills, etc., very close to what Tiersma calls “operative legal documents” (1999: 139).

Legislative texts: the written sources of a legal order, which in our case is the Greek legal order.

¹ <http://hnc.ilsp.gr/>

1.2 The Greek legal order

“Legal order” refers to the aggregation of all the written and non-written rules which regulate the external behaviour of the members of a community. With respect to the Greek legal order, the non-written rules correspond to the mores and customs of the Greek community, while the written legal sources constitute a quite complex, but hierarchically organised system of laws.

In particular, the written part of the Greek legal order consists of the so-called “special Law”, i.e. the Greek Constitution, the European Union Law and the International Law, as well as the “typic” and the “substantial” laws, which constitute the “common Law”. In this project we have excluded EU and International Law, because our research interest is restricted to untranslated texts originally redacted in Greek.

2. Properties of the legal language

2.1 The desirable characteristics

Researchers representing different scientific fields and studying different legal systems, conclude that there is a set of properties which legal language should present. Among them, Knapp (1991: 4-10) listed some properties which should be observed in the legal language and notions: accuracy, consistency, discernibility, unemotionality, intelligibility, unambiguity, constancy. Recently, Bhatia (2010: 38) suggested some desirable characteristics of legislative language, which are clarity, precision, unambiguity and all-inclusiveness, defined in terms of comprehensibility, accessibility and transparency. Similarly, Panaretou (2009: 58) has observed a “legal paradox”: the laws must be precise, clear and unambiguous, but, at the same time, general, widely applicable and inclusive. In order to combine the characteristics listed above, the legal texts may result in being either rigid or vague, or rather both.

2.2 Lexico-grammatical features of the laws

The rigidity or the vagueness, which often characterises the language of legislative texts, is usually related to some linguistic properties of these texts, namely the lexical and grammatical choices made by the authors. Tiersma (1999: 203-10) and Panaretou (2009: 75-119) have made a thorough description and classification of such features listed as follows:

- **Technical vocabulary**, e.g. *ενάγων* (= plaintiff); *λιπομαρτυρία* (: the offense of defaulting witness); *ελευθεροκοινωνία* (= pratique); *υπερθεματιστής* (= tenderer); *καταπίστευμα* (= trust); *αναιρεσείων* (= appellant).
- **Archaic, formal, formulaic, unusual words and forms**, e.g. *ανήκεστος βλάβη* (= irreparable damage); *ο κρινόμενος* (<participle> “the judged”); *μονιμοποιητέος* (<verbal adjective> “someone (employee) who must become permanent, the *permanent-able”).
- **Binomials – multinomials**, e.g. *οι διάδικοι ή οι νόμιμοι αντιπρόσωποί τους ή οι δικαστικοί τους πληρεξούσιοι* (= the parties or their legal representatives or their judicial attorneys); *πραγματικά ή νομικά ελαττώματα* (= actual or legal defects); *οι ενέργειες και οι παραλείψεις* (= the actions and the omissions).
- **Impersonal constructions and overuse of passives** (in typic laws), e.g. *κυρώνεται* (“something is ratified”); *απαγορεύεται* (“it is prohibited”); *υποχρεώνεται* (“he/she is obliged”).
- **Preference to nouns instead of verbs & overuse of verbal nouns** (combined with nominalisation) e.g. *διαλειτουργικότητα* (= interoperability), *πραγματοποίηση* (= realisation), *απασχολησιμότητα* (= employability).
- **Modal verbs**: *πρέπει* (“must, shall”, normally expressing deontic necessity), *μπορεί*: (“may, can”, normally expressing deontic possibility, but also expressing epistemic possibility only when describing the facts).
- **Long and complex sentences**
- **Overuse of the conjunctions**: *και, ή, είτε...είτε* (: “and”, “or”, “either...or”), e.g. “Για τους σκοπούς της παρούσας σύμβασης, ο όρος διεθνής μεταφορά σημαίνει οιαδήποτε μεταφορά στην οποία με βάση τη συμφωνία μεταξύ συμβαλλομένων μερών, ο τόπος αναχώρησης και ο τόπος προορισμού, ανεξαρτήτως εάν υπάρχει ή όχι διακοπή της μεταφοράς ή μεταφόρτωση, βρίσκονται είτε εντός των εδαφών δύο συμβαλλομένων κρατών, είτε εντός του εδάφους ενός και μόνον συμβαλλομένου

κράτους...”(N. 3006. K.No.B. 50 (2002): 789).

Our research was based on quantifying some of the above features and using them in order to define the stylometric profile of the Greek Legal Corpus.

3. Corpora and Features

The aim of this study can be summarised in three different but highly related research questions:

1. What is the stylometric profile of the Greek law texts and how can this be compared with the stylometric profile of Greek language corpora?
2. How significant is the impact of each stylometric group in the discrimination of legal texts?
3. Which specific stylometric features related to the legal language could provide reliable genre discrimination?

In order to investigate the abovementioned research questions we used both the Hellenic National Corpus (HNC) and the Greek Legal Corpus (GLC). HNC is currently the biggest written corpus of Modern Greek and consists of many different genres and topics (Hatzigeorgiu et al., 2000)². GLC is a collection of contemporary Greek legislative texts containing:

- the current Greek Constitution
- the codified Civil and Criminal Law

as well as randomly selected balanced samples of

- ‘typic’ laws
- Presidential Decrees
- Ministerial Decrees
- Decentralised Government Acts

The basic descriptive statistics of the two corpora are displayed in the following table (Table 1) :

Corpora	Texts (N)	Average text length	Median	St. Deviation	Minimum text length	Maximum text length
HNC	45.691	755	494	2.374	10	166.576
GLC	1.594	1.224	991	2.284	504	45.333

Table 1: Descriptive statistics for HNC and GLC

Both corpora underwent Part-of-Speech tagging using the Tree Tagger developed by Schmid (1994). The Tree Tagger is a probabilistic tagger, where transition probabilities are estimated using a decision tree and provides better results than HMM- and Trigram taggers. This tagging technique can achieve up to 96% accuracy on the data. The training of the Greek parameter file, used in our study, is based on a 500.000 words tagged corpus. The data have been tagged for all grammatical categories.

In order to define the stylometric profile of the HNC and GLC, we measured six broad sets of stylometric features which contain both lexical and sublexical units. Each set groups a number of variables which function complementary and all together approximate a specific textual construct. Although the listing is not exhaustive, it contains most of the variables that have been employed in modern stylometric research and we consider them as sociolinguistically neutral. All the features used in this study are the following:

Lexical “richness”

- *Yule’s K*: Vocabulary richness index that exhibits stability in different text sizes (Tweedie & Baayen, 1998).

² We acknowledge the fact that the HNC developed by ILSP is not a balanced corpus of Modern Greek with sufficient size to reflect linguistic generalizations. However, the aim of this study was to identify specific properties of the Greek legal language and use them for the stylometric profiling of Greek legal texts.

- *Lexical Density*: The ratio of functional to content words frequencies in the text, also known as *Functional Density* (Miranda & Calle, 2007).
- *% of Hapax- and Dis legomena*: The percentage of words with frequency 1 and 2 in the text segment.
- *Dis-/Hapax- legomena*: The ratio of dis legomena to hapax legomena in the text segment, indicative of authorship style (Hoover, 2003).
- *Relative entropy*: It is defined as the quotient between the entropy of the text and its maximum entropy multiplied by 100. Maximum entropy for a text is calculated if we assume that every word appears with frequency 1 (Oakes, 1998: 62).

Word length

- Average word length (per text) measured in letters.
- Word length distribution: The frequency of words of 1, 2, 3 ... 14 letters long normalized in 1,000 words sample.

Sentence length

- The average sentence length measured in words.
- The standard deviation of the sentence length

Part-of-Speech frequencies

- The frequency of each Part of Speech tag expressed as percentage of the text size.

4. Statistical analysis

In order to examine in detail the way each of the six variable sets relates to the legal genre, we used *Multiple Analysis of Variance* (MANOVA). MANOVA is a multivariate statistical analysis which is specifically designed to analyze the effect of one or more categorical independent variables on two or more continuous dependent variables. Although the problem could be tackled with multiple univariate tests, the overall α -level error (Type I) will be inflated and the probability to reject the null hypothesis when it is true is increased. MANOVA controls against Type I error and offers an omnibus test of significance that takes into account the effect of the independent variable(s) to all the dependent variables simultaneously (Weinfurth, 1995). Furthermore, MANOVA is particularly useful if the dependent variables are conceptually related and there is a moderate intercorrelation between them. Since each variable group contains stylometric variables that attempt to measure the quantitative expression of a specific textual construct, we expect a certain amount of redundancy. MANOVA takes into account this shared common information and tests the effect of the independent variable(s) in a multivariate way (i.e. taking all dependent variables at once). Another reason why a multivariate approach is preferable in our data is that it can detect differences when groups differ on a system of variables (Huberty & Morris, 1989). MANOVA finds a linear composite of the dependent variables that maximizes the separation of the categories that form the independent variable.

A non-significant MANOVA result means that the specific set of dependent variables examined simultaneously do not differ across the categories of the independent variable and no further analysis should be made. A significant MANOVA however indicates that at least one dependent variable differs significantly across the categories of the independent variable. In the relevant literature most researchers perform univariate tests (t tests in our case) with adjusted α level (Bonferroni correction) for each of the dependent variables in order to detect which variable is different between the categories of the independent variable (Hair Jr, Anderson, Tatham, & Black, 1995; Stevens, 2002). This procedure however has been criticized (Bray & Maxwell, 1982; Huberty & Morris, 1989) among others for confusing the univariate with the multivariate research questions. Since genre and language structure interact in complex and multilevel ways we chose to further explore significant MANOVAs with *Discriminant Function Analysis* (DFA). Conducting DFA following a significant multivariate effect allows the researcher to investigate in detail the linear composites of the dependent variables and to determine their structure as well as the weights of each dependent variable (Meyers, Gamst, & Guarino, 2006).

5. Results

5.1 Feature group importance

In our data we performed separated MANOVAs for each one of the six stylometric groups by using the author's gender as the independent variable. The multivariate statistic we calculated was Hotelling T^2 which is the multivariate counterpart of the univariate t statistic. Furthermore, partial η^2 was calculated indicating the percentage of the variance explained by the combined dependent variables. The following histogram displays the importance of each feature group based on η^2 :

Figure 1 Feature group importance using Partial η^2

All stylometric groups had a multivariate statistically significant effect in the discrimination of the legal texts from the texts belonging to the HNC. The group that accounts for the biggest amount of variance is Lexical 'richness' (19.1%) followed by Part of Speech frequencies (15.4%), Word Length (12.7%) and Sentence Length (11.5%). For each of the four variable groups that Hotelling T^2 was found statistically significant we performed DFA in order to further explore the linear composite structure and to assess each dependent's variable contribution to legal genre discrimination.

5.2 Lexical 'richness' DFA

The Discriminant Function Analysis using Lexical 'richness' variables as independent and text genre as dependent showed that 3 variables exhibit a statistically significant difference between the GLC and the HNC. In order to assess the importance of each variable to the genre discrimination, we examined the factor structure coefficients (absolute values), i.e. the correlations between the variables in the model and the discriminant functions. Depending on the coding of the genre factor, coefficients were positive or negative indicating whether a specific variable relates to the legal genre or the general language. The structure coefficients are displayed in the following histogram:

Figure 2 DFA factor loadings using Lexical “richness” features

The inspection of the factor loadings reveals that hapax legomena relate to the general language (positive coefficient) and Yule’s K and Lexical Density relate to the legal language. Yule’s K is a measure of lexical repetition which increases as the vocabulary of the text tend to be formulaic. Indeed, the mean of Yule’s K in HNC is 74.13 while in GLC is 93.38, which means that GLC texts use vocabulary that is repeated frequently. Lexical density is the second variable that can be considered as legal stylistometric index. Legal texts have a mean Lexical Density of 1.39 while HNC has a mean of 1.1. From this we can conclude that the legal texts present higher ratio of content to function words than the texts from general language. This higher ratio can be attributed to the high terminology load that characterizes the specific genre. Interestingly, Yule’s K correlation with the GLC can be utilized further to understand why hapax legomena correlate with HNC. Legal texts have small portion of hapax legomena (24%) compared to the HNC (43%) since their vocabulary is highly repeated resulting in high values of Yule’s K. From this perspective, we can conclude that hapax legomena is not a characteristic stylometric variable of the general language, but their decreased presence can be correlated with the legal genre as an indirect effect of the vocabulary repetition.

5.3 Part of Speech DFA

The DFA using Part of Speech variables as independent and text genre variables as dependent also showed that 3 variables differ significantly between the GLC and the HNC. Using the same analysis, we present the structure coefficients of each variable in the following histogram:

Figure 3 DFA factor loadings using Part of Speech features

The analysis of the factor loadings reveals that the legal texts have a higher frequency of nouns (26.6%) compared to the HNC (21.5%). On the other hand, HNC presents significantly higher percentages of verbs (11.15%) and adverbs (5%) compared to the GLC (8% and 3.8% respectively).

The statistical data correlate closely with some features of the legal language as so far observed. Such features are the preference to nouns instead of verbs plus the overuse of verbal nouns combined with the abundance of impersonal constructions. This deviation could be blamed for the rigidity and vagueness, which legal texts are often criticised for.

5.4 Word Length DFA

The DFA using Word Length variables as independent and text genre variables as dependent showed that 11 variables differ significantly between the GLC and the HNC. We present the structure coefficients of each variable in the following histogram:

Figure 4 DFA factor loadings using Word Length features

The factor loadings of the word length spectrum reveal a strong correlation between legal genre and word length categories. In our analysis, all words greater than or equal to 9 characters (up to 13 characters) correlate with legal genre. Furthermore, 1 letter words have a higher frequency in legal texts, an observation which could be indirectly linked to the grammatical category of these words, which belongs almost always to articles. Since nouns have a significantly higher frequency in the GLC, we expect that an analogous increase could occur in articles. Another factor which could amplify the importance of one letter words concerns the tokenization rules used in the processing of the corpora. Since we used a simple regular expression tokenizer, we could not disambiguate named entities, acronyms and document structures in the texts. In many legal texts we encountered, for instance, a numbering structure which our tokenizer interpreted as one-letter tokens. The same occurred with abbreviations such as ‘ν.’ which stands for ‘νόμος’ (law) and is used very frequently as a quick reference to previous legislation codes.

5.5 Sentence Length DFA

The DFA with Sentence Length variables as independent and text genre variables as dependent showed that both variables of sentence length (Average Sentence Length and Standard Deviation of Sentence Length) differ significantly between the GLC and the HNC. We present the structure coefficients of each variable in the following histogram:

Figure 5: DFA factor loadings using Part of Speech features

Both Average Sentence Length and Standard Deviation of Sentence Length (sd ASL) correlate significantly with legal genre. The sd ASL index exhibits high factor loading, which means that texts belonging to the legal genre contain on average not only bigger sentences but also sentences whose length varies significantly between them.

6. Conclusions

Legal texts have a distinct and highly recognizable stylometric profile. All groups of stylometric measures in the GLC were found to show statistically significant differences with respect to the corpus of the general language (HNC). More specifically, the most distinctive stylometric characteristics of the legal texts are:

- Both, the ratio of content to function words (Lexical Density) and the vocabulary repeatability (Yule's K) are systematically higher in legal texts compared to texts in other genres.
- High frequency of occurrence in a specific grammatical category, i.e. nouns.
- High word length (over 8 characters).
- High sentence length with measurements that span across a wide range (high standard deviation).

The above findings confirm previous theoretical studies of the legal genre and quantify many of the qualitative observations attested there. Namely, factors such as the formulaic language, the preference to nouns and impersonal constructions, the use of technical vocabulary, and the length and complexity of sentences characterising the Greek law texts, all agree with the abovementioned statistics, as well as with the descriptions which relate such features to the lack of precision and transparency of the legal texts.

7. Acknowledgments

This study is funded by the Special Account for Research Grants. We would also like to thank Dr Effie Georgopoulou for providing us the Modern Greek parameter file in order to use TreeTagger in our research.

líyo: TOWARDS GRAMMATICALIZED VERBAL DIMINUTIVIZATION?¹

Costas Canakis

University of the Aegean, Greece

c.canakis@sa.aegean.gr

ABSTRACT

I argue that líyo has undergone semantic attenuation, losing most of its literal meaning in certain constructions, and has grammaticalized from a lexically independent quantifier to a verbal diminutivizer. Part and parcel of this change is the (inter)subjective interpretation of líyo in certain construction. Motivation for this process is provided by MGr interactional ethos, a factor discussed in universal tendencies in the semantics of diminutives. Moreover, primary evidence on the equivalents of líyo in other Balkan languages suggests that verbal diminutivization with líyo may be an area feature. Therefore, líyo may present us with a case of semantic change motivated by sociopragmatic considerations.

1. Introduction: Setting the Scene

Modern Greek *líyo*, typically rendered as ‘(a) little’, has a number of well-known idiomatic uses beyond the relatively straightforward (1) and (2), where it functions as an adjective and adverb, respectively:

- (1) *évala líyo yála ston kafé su* (but cf. *évala líyo_n/líyo_i záxari_i ston kafé su*).
‘I put a little milk in your coffee’ (but cf. ‘I put a little sugar in your coffee’).
(2) *se íða polí líyo*.
‘I saw very little of you.’

Such uses of *líyo*, exemplified in (3), along with morphologically transparent diminutivization, have been identified as “exhibiting pragmatic force in polite interaction” (Sifianou 1992a: 160, 1992b); specifically, Sifianou argues that they function as positive politeness markers rather than mitigating devices in an attempt to minimize the imposition arising from requests (Sifianou 1992a: 170-172; cf. also Makri-Tsilipakou 2003: 700):

- (3) *mu pjánis líyo to stilo? / mu pjánis to stilo líyo?*
‘Can you grab the pen for me?’

According to Sifianou (1992a), *líyo* here, rather than minimizing the imposition by minimizing the action requested, is rather an informal variant of *parakaló* ‘please’ and can be used instead of or along with it; especially as it is positionally flexible just like *please*. She also mentions that this use of *líyo* is not peculiar to Greek: Brown and Levinson (1987) in Tamil and Malagasy the words for *please* literally mean ‘a little’ (Ibid.: 169; Jurafsky 1996: 558). On the other hand, she suggests that “[t]he Greek *líyo* seems to be more flexible than its English equivalent. It can also collocate with various verbs, and the grammatical constructions within which it can be employed are less restricted” (Sifianou 1992a: 169).

¹ Many thanks are due to Mary Sifianou, Eleni Antonopoulou, and Angeliki Athanasiadou for their help in this paper, earlier versions of which have been presented at graduate seminars at the Universities of Leuven, Aarhus, and Thessaloniki. I have benefited from the insightful comments of these audiences and discussions with colleagues Bert Cornillie, Nicole Delbecque, Marianthi Makri-Tsilipakou, Argiris Archakis, and Kiki Nikiforidou.

Based on these findings regarding examples such as (3), I will argue that *líyo* here serves an unambiguous hedging or diminutivizing function on the verb of request. In this sense, *líyo* in (3) has lost most of its original lexical meaning and has grammaticalized into a marker of verbal diminutivization. Moreover, this function seems to be related to particular contexts, in other words to specific constructions. This is in keeping with Sifianou's (ibid.: 169) claim that in certain contexts *líyo* seems to "ha[ve] lost its literal force and serves strictly politeness purposes."

However, in other instances, exemplified in (4) and (5), *líyo* is ambiguous between a grammaticalized hedge and a *bona fide* adverbial quantifier:

(4) *aníyis líyo tin porta? / aníyis tin pórtá líyo?*

'Can you get the door? / Can you open the door just slightly.'

(5) *éla líyo na se do! / éla na se do líyo!*

Literally: Come over so I can see you, 'Come over to see me!'

Thus, (4) may be construed as a request to open the door a little or a polite request to open the door (irrespective of degree of openness). Along the same lines, (5) may be construed as a request for a brief period of one's time or as a polite request for a visit of indeterminate length. Note that the quantifier interpretation is not available for (3).

On the other hand, *líyo* is also used with a variety of verbs that have nothing to do with requests and in constructions that function mostly as statements, as in (6) through (9) below:

(6) *δulévo líyo*. 'I am working.'

(7) *tróo líyo*. 'I am eating.'

(8) *δjavázo líyo*. 'I am reading/studying.'

(9) *ksirízome líyo*. 'I am shaving.'

In (6) through (9) –where, incidentally, *líyo* is positionally inflexible, in contrast to examples (3-5)– word stress plays a crucial role in disambiguation and, therefore, in interpretation. When main stress is on *líyo*, it functions as an adverbial quantifier and the interpretation is that one works, eats, or reads or little.² On the other hand, when main stress is on the verb, it is interpreted as a hedge, indeed as a verbal diminutivizer comparable to (yet distinct from) the increasingly used prefix *psilo-* (literally 'thin' in the sense of 'a little' or '(s)lightly') as in *psilodulévo* '-work', *psilotróo* '-eat', *psilodjavázo* '-read', or even *psilomalakízome* '-being a jerk/wanker', etc. (cf. Makri-Tsilipakou 2003: 700).³ In (10), where we have an overt object, *líyo* is flexible but the same restrictions regarding stress apply:

(10) *mazévo líyo to spíti. / mazévo to spíti líyo*. 'I am tidying up the house.'

1.1 Summing Up: Aims and Thesis

Sociolinguistic research has so far dealt with *líyo* in the context of diminution and routinely offered cogent interpretive accounts relating to politeness in informal discourse (Sifianou 1992a, 1992b, Badarneh 2010) and gender issues (Makri-Tsilipakou 2003 and the bibliography listed there). Moreover, Jurafsky (1996), in a detailed cross-linguistic treatment of diminutives, has offered further insights on the semantics of diminutive forms, especially mechanisms relating to semantic change, such as bleaching (among others).

However, even the actual examples used in Sifianou (1992a) seem to allow for additional directions as well, namely in terms of grammaticalization and subjectification in the context of certain constructions motivated by Greek "cultural ethos" (cf. Brown and Levinson 1987) which is the main focus of her research. These become more apparent if one considers preliminary evidence from corpus data, as obtained for the purposes of the present analysis, from the CGT and GWAC.⁴

² Note, incidentally, that a quantifier interpretation is not available in (9).

³ Cf. note 12.

⁴ *Corpus of Greek Texts* (see Goutsos 2003) and Sketchengine's *Greek Web as Corpus*.

Specifically, I will show that *liyo* (and related, further diminutivized forms *liyáki* and *liyuláki*) has undergone semantic attenuation (cf. bleaching), losing most if not all of its literal meaning (along with its stress) in certain constructions, and has grammaticalized from a lexically independent quantifier to a verbal diminutivizer. Part and parcel of this change is the subjective interpretation of *liyo* in (6)-(9) above. Moreover, I will investigate whether this process is motivated by Greek interactional ethos and the importance attached to friendly, informal politeness (as argued for in Sifianou 1992a, 1992b), a factor discussed in the context of universal tendencies in the semantics of diminutives (Jurafsky 1996). Indeed, primary evidence from data on the equivalents of *liyo* in other Balkan languages, such as BCMS⁵ and Albanian, suggests that verbal diminutivization with *liyo* may be an area feature. Crucially, then, *liyo* may present us with a case of semantic change motivated by sociopragmatic considerations.

2. On Grammaticalization

Over the last two decades, there has been a boom of functionally geared research on phenomena described by the term *grammaticalization*, credited to Antoine Meillet. Despite differences, such treatments share an understanding of lexical items progressively losing (at least part of) their lexical status and acquiring grammatical or function word status. To quote from Meillet (1912/1926 quoted in Cambell and Janda 2001: 95 in their translation), who has influenced more recent researchers,

[Besides analogy], another process consists in the change of an autonomous word into the role of a grammatical element Th[is]...process...[, involving] the attribution of grammatical character to a formerly independent word...[, is one of] only [two] ways by means of which new grammatical constructs are formed (Meillet 1921/1926: 131).

The ‘grammaticalization’ of certain words creates new forms, introduces categories that did not use to receive linguistic expression, [and] transforms the overall system (Meillet 1912/1926: 133).

Campbell and Janda (2001: 95) note that grammaticalization is seen as typically involving “a concurrent ‘weakening’ of both meaning and phonetic form” and as represented by the overall cline *lexical* > *syntactic* > *morphological*. That is, a lexical item becomes a form word with syntactic function and may end up as a morphological marker, an affix. Grammaticalization is then a change from less to more grammatical status.

In a similar vein, Hopper and Traugott claim that grammaticalization is “the change whereby lexical items and constructions come in certain linguistic contexts to serve grammatical functions and, once grammaticalized, continue to develop new grammatical functions” (2003: xv). They caution the reader that in the first edition of their book, in 1993, they defined grammaticalization as *a process* instead of *a change*. However, as work on grammaticalization “has progressed, it has become clear that the definition of grammaticalization as a process has been misleading. To some it has suggested that grammaticalization is conceived as a force with an impetus of its own independent of language learners and language users. This was never intended” (Ibid.: xv).⁶ They argue that students of grammaticalization encounter data showing that “morphosyntactic changes are replicable across languages and across times; furthermore, they have a very strong tendency to go in the same direction [...]” (Ibid.: xv).

In examples (3-9), and especially (6-9), we see evidence of the weakening of both the semantic content and the phonetic form of *liyo*. Motivation for the grammaticalization of *liyo* as a diminutivizer in such cases seems to be high for, in effect, *liyo* “names” diminution (cf. Jurafsky 1996: 542-543): it stands in a

⁵ Bosnian, Croatian, Montenegrin, Serbian. It usually appears as BCS in the relevant literature.

⁶ Cf. the special issue of *Language Sciences* (2001, vol. 23) devoted to a scrutiny of grammaticalization, especially Campbell and Janda (2001), Campbell (2001), Joseph (2001), Janda (2001), and Newmeyer (2001). Campbell (2001: 113) notes that grammaticalization is derivative and “relies on other processes and mechanisms of linguistic change which are independent of” it. Yet, these criticisms do not question the value of research on this phenomenon but rather claims for a self-contained “grammaticalization theory”. I make no such claims here.

metonymic relationship to it,⁷ similar to the relationship attested for volitional verbs to modals or/and future tense markers documented in the literature for many languages, and for Balkan languages in particular: cf. MGr *thélo ina* ‘want to’ > *thélo na* > *thēna* > *tha* ‘will’ future marker (cf. Joseph 1983, 2001,⁸ Veloudis 2005); BCMS *hoću* ‘want’ > *ću* future marker cf. ‘will’ (cf. Sandfeld 1930).

I would like to argue that *liyo* is grammaticalized in Modern Greek (MGr). Primary evidence suggests that *liyo* has undergone a first round of grammaticalization functioning as a positive politeness marker (predominantly though not exclusively) in requests in informal settings. The function as a verbal hedge or diminutivizer could then be a further, even more general step in this process, whereby use of *liyo* with verbs is progressively generalized and comes to weaken their illocutionary force. This step is motivated by two factors. On the one hand, in MGr diminutive morphology does not extend to verbs. On the other hand, *liyo* is, in effect, a metonymy for diminution and a prime candidate for such a role as an adverbial. In other words, given structural restrictions and sociopragmatic exigencies *liyo* has come to fill a gap – to quote Meillet, again: it has come “to introduce a category that did not use to receive linguistic expression”.⁹

Justification for this claim can also be found in Jurafsky (1996: 541-542), who proposes a universal radial category for the meaning of the diminutive in which ‘small[ness]’ serves as the prototype while many other meanings are extensions from the prototype. He also notes the tendency for “meaning changes from the more informative and specific to the more abstract and vague” (Ibid.: 540), a process variously known as bleaching, generalization, or desemanticization. Moreover, he suggests that the meanings of the diminutive in a particular language will develop diachronically from central to peripheral senses of the category (Ibid.: 543). Specifically, the diminutive may shift from smallness to approximative hedges to metalinguistic hedges, from the physical to the linguistic or textual world (Ibid.: 560), which is what I claim to be the case with *liyo*.

Last, Jurafsky (Ibid.: 541) draws on Traugott and König (1991) who “propose three tendencies for meaning to become more removed from the external world, and more subjective or evaluative”, summarized here as a) external situation → internal situation; b) external/internal situation → textual/metalinguistic situation; and c) external/internal/textual situation → speaker’s subjective belief state. In section (3), I show that subjectification is another relevant way of looking at *liyo*, especially as it correlates strongly with grammaticalization, although it does not entail it (Traugott 2010: 38, Athanasiadou et al. 2006: 5).

3. On (inter)subjectivity and (inter)subjectification

Research on subjectivity and subjectification, and more recently intersubjectivity and intersubjectification (Traugott 2003, 2010, Cuyckens et al. 2010), has mostly developed along with work on grammaticalization. According to Finegan (1995: 1), “*subjectivity* [...] concerns the expression of the self and the representation of a speaker’s (or, more generally, a locutionary agent’s) perspective or point of view in discourse – what has been called a speaker’s imprint. In turn, subjectivisation (or *subjectification*) refers to the structures and strategies that languages evolve in the linguistic realisation of subjectivity or to the relevant processes of linguistic evolution themselves.” He further specifies that subjectivity has to do with the effect of the involvement of a locutionary agent *on the linguistic expression of self*, an effect which is registered in the formal shape of discourse (Ibid.: 1, italics mine).

This view of subjectification aptly describes the use of *liyo* in examples (3-5) above, where the speaker employs it as a positive politeness (solidarity) marker or in (6-10), where it marks speaker attitude towards

⁷ Jurafsky (1996: 555), in his discussion of the diminutive as a radial category, he proposes a mechanism he calls *lambda abstraction* (related to the generalization mechanism) “which takes one predicate in a form and replaces it with a variable” yielding second-order predicates.

⁸ Although Joseph (2001) is critical of grammaticalization as an independent process, I refer to his work here as I make no such claim. On the other hand, cf. Veloudis (2005: 306), who cautions that grammaticalization poses problems which are tacitly or/and arbitrarily solved in other theories.

⁹ Note that the productive prefix *psilo-* tends to be used with a trivializing intention (cf. Makri-Tsilipakou 2003: 700) (cf. Jurafsky’s 1996 *approximative*) and although it may share some of its meaning with *liyo* it cannot be equated with it.

his/her utterance, weakening its force. What is common in both cases is that *liyo* is used to express affect. As MGr verb morphology does not allow for morphological diminutive marking on the verb in the form of an affix, *liyo* is used as a verbal diminutivizer, not unlike the diminutivized nominals *kafedáki*, *neráki*, etc. This use seems to be motivated by MGr cultural ethos as attested in the work of Sifianou (1992a, 1992b).

In more recent research it has been noted that there are two competing notions of subjectivity and subjectification, as developed by Traugott (e.g., 1995, 2003, 2010) and Langacker (e.g., 1990, 2006). Although not incompatible, they have different genealogies and their similarity is probably the result of both scholars having anchored subjectification to grammaticalization (Athanasiadou et al. 2006: 5). However, as work on subjectification has progressed, both authors have increasingly clarified matters. Specifically, Traugott (1995: 31-32) has used the term to refer to “a pragmatic-semantic process whereby ‘meanings become increasingly based in the speaker’s subjective belief state/attitude towards the proposition’, in other words, towards what the speaker is talking about (Traugott 1989: 35).” She concedes that this is a very broad characterization (contrasting with a more narrowly defined process described by Langacker (1990: 17) as “the realignment of some relationship from the objective axis to the subjective axis”). Traugott claims that

Subjectification is evidenced in lexical as well as grammatical change. Examples in the lexical domain include the development of illocutionary speech-act verb meanings from locutionary (and ultimately often non-locutionary) meanings, for example: *agree* (originally ‘be pleasing, suitable’) [...]. ‘Subjectification in grammaticalisation’ is, broadly speaking, the development of *a grammatically identifiable expression of speaker belief or speaker attitude to what is said.*” Traugott (1995: 32, italics mine)

Considering the examples with *liyo* in this light, we can make the following points. Already in (1) we have traces of the process of subjectification of *liyo*. One can ask for a little sugar using the form *liyi*, which expectedly modifies the feminine noun *záxari*, or the neuter form *liyo*. One can even ask for *liyi zaxarítsa* or *liyo_n zaxarítsa_f* diminutivizing the nominal. This violation of, otherwise strictly observed, gender agreement between modifier and nominal is an indication of the more subjective meaning of *liyo* in this construction. Moreover, as it obscures the distinction between adjectival and adverbial *liyo*, it may be argued that in *liyo záxari* we do not have a *bona fide* quantifier, but a quantifier-plus-affect marker. We may, moreover argue that, in this construction, the form *liyo* could modify either the verb or the nominal (indeed, if we stick to its form, then we have to assume that it is an adverbial, syncretically construed as an adjective). This indeterminacy of word class is also indicative of grammaticalization. On the other hand, habitual coding of speaker-attitude or/and affect with *liyo* in examples (3-5) and (6-10) offers further evidence of subjectification, indeed of *intersubjectification*, to which I turn next.

More recently, Traugott (2003, 2010) revisits her work on subjectification, intersubjectification, and their relation to grammaticalization. She defines subjectivity as “the development of expressions the prime semantic or pragmatic meaning of which is to index the speaker’s viewpoint on what she or he is saying or speaking about” and distinguishes it from intersubjectivity, “cases [where] expressions also develop marking attention to the addressee’s self-image” (2010: 29). Her hypothesis is that both of these “involve the reanalysis of pragmatic meaning as coded semantic meanings *in the context of speaker-hearer negotiation of meaning*” (Ibid., italics mine). She further claims that, although subjectification and intersubjectification are independent of grammaticalization, they are linked to it “for reasons relating to the various functions of grammar” (Ibid.).

On this basis, *liyo* in examples (6-10), where it expresses the speaker’s viewpoint about his/her utterance, is an instance of subjectification, whereas examples (3-5) are identifiable instances of intersubjectification, as “the development of the speaker’s attention to addressee self-image” (Ibid.: 60) or as “expressing attention to the hearer’s self” (Cuyckens et al. 2010: 1). In the latter case, the speaker is tending to the addressee’s face needs. While both of these processes arise in the context of the negotiation of meaning between interlocutors, a question that could be asked is whether they are somehow ordered. Traugott (2010: 35-36, cf. also Traugott and Dasher 2002: 225) suggests that the relation of these mechanisms can be schematized as *non-/less subjectivized* > *subjectivized* > *intersubjectivized* and used heuristically. If the above syllogism is correct, then intersubjective uses of *liyo* (3-5) are more likely to have developed from subjective ones (6-10). Last, as I have been arguing for grammaticalization of *liyo*, it is worth noting that, for Traugott (2010: 41), “[i]ntersubjectification intersects less extensively with

grammaticalization. In most languages it is grammaticalized only into some discourse markers and interjections.”

I have shown that *líyo* has a range of uses crucially tied to subjectivity. It is not only used as a quantifier but also habitually employed in coding speaker-attitude, affect, and/or solidarity. I argue that the former is a more objective and the latter a more subjective interpretation linked with an ongoing process of grammaticalization through subjectification of *líyo*. This claim receives serious support given the high degree of productivity of *líyo* in this diminutivizing function in examples (6-10), which is, arguably, linked –if not ultimately traced– to its use in requests. However, it has been repeatedly observed that it is not isolated lexical items that grammaticalize, but rather lexical items in *constructions* (Trousdale and Traugott 2010: 13, Noël 2007), a point to which I turn next.

4. *líyo* Constructions

From the beginning of this paper, I have been talking of non-literal uses of *líyo*. A closer look at its distribution seems to warrant a constructionist approach: there are a number of distinct, yet related, *líyo*-constructions, each a form-and-meaning pairing that could not be attributed to the lexicon without missing out on crucial generalizations regarding linguistic structure (cf. Goldberg 1995, 2006) as well as sociolectal variation. I will attempt to briefly outline an account of subjectification and grammaticalization of *líyo* as crucially linked to specific constructions.¹⁰

According to (Lehmann 1992: 406)¹¹ “grammaticalization does not merely seize a word or morpheme [...] but the whole construction formed by the syntagmatic relations of the elements in question”. Trousdale and Traugott (2010: 13) note that “[d]ifferent models of construction grammar have made it possible to define more explicitly in what kind of construction grammaticalization starts, what semantic-syntactic mismatches arise as a result of gradual decategorialization, and what kinds of alignments are made. These issues rest on the crucial premise that constructions are grammatical primitives, and as such are both the source and outcome of grammaticalization.”

Goldberg (1995: 1), in her seminal work on constructions argues that “[p]articular semantic structures together with their associated formal expressions must be recognized as constructions independent of the lexical items which instantiate them.” This view is based on the assumption that there is no strict division between the lexicon and syntax: although lexical and syntactic constructions differ in internal complexity, they “both pair form with meaning” (Ibid.: 7). Constructionist approaches to language rest on the view that languages are constructed “on the basis of the input together with general cognitive, pragmatic, and processing constraints.” (Goldberg 2006: 3). It is assumed that constructions, i.e., “learned pairings of form with semantic or discourse function,” appear at all levels of grammatical analysis (Ibid.: 5). A linguistic pattern is a construction to the extent that “some aspect of its form or function is not strictly speaking predictable from its component parts or from other constructions recognized to exist”. Moreover, “patterns are stored as constructions even if they are fully predictable as long as they occur with sufficient frequency” (Ibid.: 5). This last point is of particular relevance here, for frequency spells out entrenchment and the *líyo* constructions I have focused on are highly entrenched.

There are several *líyo* constructions as exemplified in (11) below, featuring both fixed, idiomatic expressions (a-f) as well as highly productive constructions (g-h) where a quantifier reading may be unavailable:¹²

- (11) examples of *líyo* constructions
 a. *úte líyo úte polí* ‘more or less, in effect’
 b. *líyo elipse [na]* ‘X got close [to]’
 c. *akóma líyo kai* ‘short of’

¹⁰ Cf. Athanasiadou (2006) for an account of the meanings of English adjectives as based on specific constructions.

¹¹ Quoted in Trousdale and Traugott (2010: 13).

¹² Marianthi Makri-Tsilipakou (p.c.) has suggested to me that *líyo* in these constructions may retain traces of its original meaning. Yet, conceding to this, as I must, does not thwart my claim for diminutivization via attenuation. Jurafsky (1995) has shown that the diminutive is a radial category with smallness in its core and several extensions. Indeed, the prefix *psilo-* seems to instantiate his “approximative” sense (Ibid.: 549), which distinguishes it from *líyo*.

- d. Def.art._i + N_i + copula + *líyos/líyi* ‘X is insufficient/ineffective; s/he leaves something to be desired’
 e. ?*líyo líyo* ‘little by little, slowly, easy’
 f. ? *líyo malákas* ‘kind of a wanker/jerk/idiot’
 cf. *metá esθánθikes líyo malákas ótan su éskase to paramíθi.* (GWAK, 91729)
 Then you-felt a-little wanker when to-you s/he-burst the fairy-tale
 ‘Then you felt like an ass when s/he let the cat out of the bag.’
 g. V dir. + *líyo* (cf. examples (3-5) above)
 h. V [1/3p]+[main stress] + *líyo* (cf. examples (6-10) above)

I will focus on the last two cases here. In (g) I offer a schematic representation of a construction instantiated by examples (3-5). I argue that Sifianou’s (1992a, 1992b) claim for *líyo* as a positive politeness marker is brought to bear in precisely this context, i.e. in directive utterances. This can be thought of a general schema covering a range of well-known forms of requests. On the other hand, (h) is instantiated by examples (6-10) functioning as hedged statements with first or third person verb forms and main stress on the verb. Although *líyo* can be described as a non-quantifying hedge in both cases, its function is different. In (g) it is intersubjective and analogous to *parakaló/please*, as corroborated by its flexible position. In (h) it is subjective and inflexible: it marks speaker attitude/affect towards one’s own utterance. One could hypothesize that (h) is a further development on the basis of (g) which is functionally salient, but more limited. This needs further investigation of a kind that might not be possible, as it requires diachronic comparison of informal conversational data. However, it is worth noting that this development would disagree with Traugott and Dasher’s (2002: 225) heuristic ordering of subjective and intersubjective meanings. Therefore this question remains open. Be that as it may, it is in specific, entrenched constructions that *líyo* has undergone semantic change (attenuation) and grammaticalized as a hedging device.

5. A Balkan all purpose diminutive out of a quantifier?

Primary evidence from Albanian and BCMS suggests that it may be possible to add yet another item to Sandfeld’s (1930) long list of common traits for the Balkan languages.¹³ If this is so, then we can potentially gain new insights into the interaction of cognitive and social factors in language contact situations. Many of the uses of *líyo* in MGr have parallels in Albanian and BCMS as seen in examples (12-14), often word-for-word equivalences (cf. 12 and 13):

- (12) MGr: *éla líyo/liyáki na se ðo , [de]!*
 ALB: *eja pak/një çik të të shof, [pra/de]!*
 BCMS: *dođi malo da te vidim!*
 Come! a-little/a-little that you I-see, [voc.partcl.]!
 ‘Come over [so I can see you a little]?’
- (13) MGr: *éla na se ðo líyo/liyáki, [de]!*
 ALB: *hajde të të shof pak/një çik [pra/de]!*
 BCMS: *dođi da te vidim malo!*
 Come! that you I-see a-little/a-little [voc. Prtcl.]
 ‘Come over [so I can see you a little], will you?’
- (14) MGr: *vále mu líyi/líyo zázari ston kafé.*
 Put! to-me a-little(f.)/a-little sugar (f.) in-the coffee
 ALB: *Më vër pak/një çik sheqer ne kafe.*
 to-me put! a-little sugar in-the coffee
 BCMS: *Stavi mi malo šećera (Gen.) u kafu.*
 Put! to-me a-little sugar in coffee
 ‘Put a little sugar in my coffee.’

¹³ I would like to thank Nesim Kaloshi for his help with the Albanian data.

The most striking similarity is the formal fusion of adjective and adverb (syncretism) in the specific examples for all three languages. According to my bilingual informant, Albanian and Greek, in particular, allow for strikingly similar constructions in many other cases that we shall not get into here. Sifianou's (1992a) observations regarding use of *líyo* as a positive politeness marker seem to extend to Albanian and BCMS where *pak* or/and *një çik* and *malo* appear in constructions schematized in (11g). According to Jurafsky (1996: 535) diminutives are cross-linguistically associated with a number of pragmatic senses, among which he lists affection and metalinguistic hedges. These meanings develop diachronically from central to peripheral senses of the category (Ibid.: 543), from the physical to the linguistic or textual realm (Ibid.: 560), which is what I have shown to be the case with *líyo* (and very likely for the Albanian *pak/një çik* and BCMS *malo*), which a metonymy for diminution (and a radial category of related senses in itself (cf. Lakoff 1987) like most entrenched linguistic expressions). Moreover, cultural ethos has arguably played a role in this development which is anchored to specific constructions.

6. Conclusions and perspectives

I have argued that that *líyo* has undergone semantic attenuation, losing most of its literal meaning (along with its stress) in certain constructions in colloquial use, and has grammaticalized from a quantifier to a metalinguistic hedge (a politeness marker and a verbal diminutivizer, i.e., a hedging device). Part and parcel of this change is the (inter)subjective interpretation of *líyo* in certain constructions. Overall motivation for this process is provided by MGr interactional ethos and the importance attached to friendly, informal politeness, a factor discussed in the context of universal tendencies in the semantics of diminutives. Last, I have shown that data on the equivalents of *líyo* in other Balkan languages, such as BCMS and Albanian, suggest that verbal diminutivization may be an area feature. Crucially, then, *líyo* may present us with a case of semantic change motivated by sociopragmatic considerations.

At this stage, a general search for *líyo* in CGT yields the following results: For 25,929 texts totaling 29,511,849 words frequency of occurrence is 0.0338846949237 % (the commonest word is *kai* 'and' with 918,730 tokens). The frequency for *liyáki* is 0.00664140020505 % and for *liyuláki* 0.000237192864466 %.

A general search for *líyo* in GWAC from a total of 149,067,023 tokens yields a frequency of 75,552 hits. The frequency for *liyáki* is 3,292 and for *liyuláki* 140 hits. This suggests that *líyo* and related forms have an overall high frequency in the language which, in turn, speaks in favor of function word status.

At a future stage, and as MGk corpora become richer (especially as regards codification of text types more or less directly relating to registers), research could benefit from a more thorough look at quantitative distributional information. Special attention should be paid to collocations of specific verbs in what we may call, generically, the *V + líyo construction* in (11h); i.e., which verbs allow/favor a diminutive construal and which do not as well as variations on this general schema. Further investigation and specification of *líyo* constructions is a prerequisite for both a rigorous account of its grammaticalization and for a continuum of (inter)subjectivity. Last, development of richer MGr corpora will allow serious investigation of sociolinguistic/stylistic distribution of *líyo* constructions.

EFFECTS OF A PROGRAM FOR STIMULATING PHONETIC AND PHONOLOGICAL AWARENESS IN PRESCHOOLERS

Elina Chadjipapa

Democritus University of Thrace, Greece

elinaxp@hotmail.com, elinaxp@helit.duth.gr

ABSTRACT

The purpose of this study is to examine the effect of an integrative program of phonetic and phonological training on the phonetic and phonological awareness of preschool children. The level of phonetic and phonological awareness of 34 children was pre and post-measured with the help of a) an articulation test created for the purposes of the study and b) a screening measure for their phonological development. Between the two measurements the experimental group followed an integrative program of phonetic and phonological training which lasted for five weeks while the control group followed the normal curriculum. The post-measurement showed no significant differences in the phonetic and phonological awareness of the two groups.

Keywords: phonological awareness, phonetic awareness, program, preschool children

1. Introduction

Phonological awareness has gained much attention over the past two decades and a number of definitions have been proposed for the term (Stanovich 1986, Yopp 1988, Tunmer 1991, Blachman, Ball, Black & Tangel 1994, Gough Larson & Yopp 1996, Τάφα 1998, Γιαννικοπούλου & Ομάδα Εργασίας 1999, Παπούλια-Τζελέπη 1997 1999, Πόρποδας 2002, Gavriilidou 2003 *Phonetic awareness and correction for children preschool and early school years. in Greek*). These researches can be classified in the following three major areas: Some of them focus primarily on the contribution of phonological awareness to reading acquisition (Stanovich 1986, O'Connor, Jenkins & Slocum 1995, Παπούλια-Τζελέπη 1997). Others emphasize the diachronic development of childrens' phonological awareness (Olofsson & Lundberg 1983 1985, Stanovich, Cunningham & Cramer 1984). Finally, a third category studies the early phonological development of children (Lundberg, Frost & Petersen 1988, Byrne et al. 1991, Brady, Fowler, Stone & Winbury 1994, QI, O'Connor 2000, Phillips, Clancy-Menchetti & Lonigan 2008). According to Snow, Burns & Griffin (1998: 51), the term 'phonological awareness' refers to a general appreciation of the sounds of speech as distinct from their meaning. When that insight includes an understanding that words can be divided into a sequence of phonemes, this finer-grained sensitivity is termed phonemic awareness. Furthermore, phonological awareness involves the auditory and oral manipulation of sounds.

Children develop the speech ability until preschool age but with different rhythms and ways. However up to the age of five years each child has conquered the complex system of the oral speech in his/her maternal language with a worldwide common process (Slobin 1992). Previous research for Greek language (Κατή 1992, Θωμαδάκη & Μαγούλα 1997, Gavriilidou & Kambakis-Vougiouklis 2011) and for other languages (Stoel-Gammon & Dunn 1985, Ingram 1989) has shown that children's speech development is based on three aspects: a) how a sound is stored in children's brain b) how sounds are articulated by children and c) the rules and the processes that intervene between "a" and "b"(Gavriilidou 2003). How the sound is stored in children's brain is related to their phonological awareness. On the other hand sound articulation is related to phonetic acquisition.

By *phonetic acquisition* we refer to the articulation of sounds. Phonetic acquisition requires the kinesthetic maturation of the articulator muscles but also the awareness of the place of articulation and the manner in which they are articulated (Gavriilidou 2003:74).

It is obvious that if one of the two functions is not completed, children will commit phonological or phonetic errors (Γαβριλίδου 2002). Such errors severely influence children's further development (Βογινδρούκας κ.ά. 2004). On the contrary, the development of language skills contributes to better

school performance and reading or learning difficulty avoidance (Lundberg et al. 1988, Byrne et al. 1991, Ball et al. 1991, Torgesen et al. 1992, Brady et al. 1994, Share 1995).

Phonological awareness, as happens with other decoding skills, is not an intuitive or naturally developed ability, as language skills may be for some children, but rather may require deliberate teaching and practice opportunities (Phillips et al. 2008).

As it has been demonstrated phonetic and phonological awareness can be raised through integrative phonetic-phonological programs held during preschool age (Porpodas 2002) or early school years. These programs should be adjusted in the school's daily practices and should include concise, playful activities which would be attractive for the pupils in order to keep children's attention and interest (Παντελιάδου 2000).

Most of the programs suggest systematic and precise activities for the phonemes, exercises for phonological treatment and exercises that introduce the equivalence between letter (grapheme) and sound (phoneme) which helps children improve their phonological awareness. The most common activities that some programs¹ suggest are related to:

- ✓ blending words at phoneme level,
- ✓ segmenting words at phoneme level,
- ✓ identifying sounds,
- ✓ rhymes,
- ✓ blending words at syllable level,
- ✓ segmenting words at syllable level.
- ✓ alliteration,
- ✓ phoneme detection,
- ✓ sound repetition
- ✓ letter - sound correspondence

Despite the promising findings, however, many questions remain unanswered, and many misconceptions about phonological awareness persist. For example, researchers are looking for ways to determine how much and what type of instruction is necessary and for whom. The purpose of the present study is to examine the effect of an integrative program of phonetic and phonological training on the phonetic and phonological awareness of preschool children

2. Method

2.1 Participants

The sample of our research included 34 children, 13 were boys and 21 were girls. When the investigation started they were all 5 to 6 years old². The children were divided in two groups, the control group (N=17) and the experimental group (N=17). The purpose of this division was to have as equal number of girls and boys as possible. Therefore the control group included 7 boys and 10 girls and the experimental group had 6 boys and 11 girls. Children from both groups were attending in the same kindergarten but in 2 different classes, in a town of the province of Kavala called Eleftheroupoli. All children were Greek native speakers and none of them had serious speech disorders.

2.2 Instrumentation and design

In January all children in both groups were pretested with an articulation test in order to evaluate children's speech level. The articulation test is presented in the paragraph 2.2. After the pre-test, children in the experimental group were daily trained according to a suggested program for 15-20

¹ These programs are suggested from: Adams et al. (1998b), Bryant et al. (1990), David - Dickson (1999), Sharon QI & O'Connor R (2000).

² In Greek pedagogical system, the one year of kindergarten when children are 5 years old is obligatory, although they can attend kindergarten from 4 years old. Thus, children from 5-6 are called preschoolers and children from 4-5 are called "young preschoolers".

minutes. The control group followed the regular school program according to the analytic program of study of the Greek kindergarten (Αναλυτικό πρόγραμμα σπουδών/ ΑΠΣ). The procedure lasted four months and at the end of May both groups were post-tested with the same evaluation test as in pretest.

2.3 Articulation Test

In order to collect information for the articulation level of the participants an articulation test was created.

The articulation test included all seventeen consonants of the Greek language, the allophones from [x], [l], [ɣ], [k]³ and the clusters [vr] [vl] [kr] [kl] [dr] [dz] [tr] [br] [xt] [b] [g] [d]. We chose these Greek clusters because they were included in every day interaction vocabulary at kindergarten. Thus it was easy to depict these every day words with pictures.

Thirty four cards with pictures were used to test the articulation of the sounds at the beginning of a word and thirty four more cards were used to test the same sounds in the middle of the word. The majority of the cards were taken from the pedagogical tool named *Πινακωτή* (Μπεζέ et al. 2002) and some of them from the Goldman and Fristoe test of articulation (Goldman, Fristoe 2000). Children were acquainted to the cards prior to the realization of the articulation test. That helped them to be aware of the vocabulary and concentrate only on the pronunciation of the words.

During the pretest and post-test all children were recorded and the data was saved in digital form.

2.4 Training Program

The training program was constructed according to the five principles suggested in Gavriilidou (2003). These five principles included:

- Errors correction according to functional system of the sounds,
- Correction of one problematic sound at a time,
- Correction through phonological oppositions⁴, always placed in the word,
- Consideration of the phoneme position in word,
- Use of phonological games and enjoyable activities in order to raise awareness and correct problematic sounds.

Moreover, one of the basic criteria of the construction of the training program was the holistic approach of language (Αϊδίνης, 2002), who suggests a teaching model where children come in contact with the written speech in an environment full of literacy. Finally, the training program was created according to the regular preschool program and according to the cross thematic curriculum framework (Διαθεματικό Ενιαίο Πλαίσιο Προγραμμάτων Σπουδών/ ΔΕΠΠΣ) and the analytic program of study (Αναλυτικό πρόγραμμα σπουδών/ ΑΠΣ) of the Greek kindergarten.

In the pretest measure it was observed that preschoolers had difficulties in articulating the following phonemes:

[ð], [r], [ks], [θ], [l]

The phoneme [ð] was articulated as [z]

The [r] as [o]

The [ks], as [ts]

The [θ], as [s] and

The [l] as [j]

Thus the activities of the program focused on these five phonemes. The training program included daily session for 15-20 minutes and lasted for five weeks. Table 1 presents the activities of the program step by step.

³ Respectively their allophones are the [χ] [κ] [j] [c].

⁴ *Oppositions of sounds capable to differentiating the lexical meaning of two words in a particular language are phonological oppositions. They are classified in Multilateral, Bilateral, Isolated and Proportional oppositions (Trubetzkij 1969).*

1 st week	1. The lucky hat: preschoolers sit in a circle one by one and wear a hat. When the music stops the child who wears the hat has to say his/her name and a word starting with the same phoneme. There is a good opportunity to get to know each other as some of them are new in the group.
	2. Learn the articulators: watch them in a mirror and name them
	3. Mustache of pencil : hold a pencil among the nose and the upper lips
	4. Playing with chocolate hazelnut spread: Place the chocolate hazelnut spread in the children's front upper and lower teeth, palate, left and right inside cheek and let them lick it.
	5. The anteater: children try to eat small pieces of fruit etc without using their hands.
2 nd week	6. Vacuum cleaner: Children are divided in two groups. Each child has a straw and tries to put as much pieces of papers in a bowl by inhaling.
	7. Honey street: Without using their hands they try to lick the honey
	8. Learning letters: Children are divided in five groups as much as the problematic phonemes. They are all sited in a circle and the music plays. When the music stops, teacher makes one of the five sounds. The corresponding group should stand up. In a higher level teacher can show cards with the letter instead of making the sound.
	9. The sweeper: Children sweep all kind of things that there are in the classroom starting with the target phonemes or including in the word.
	10. The burning ball: The teacher throws the ball and says a word. The child should find another word starting with the same phoneme and the rest of them count to ten. When he/she founds it throws the ball to another child and the game goes on.
3 rd week	11. [ksaplono][ksopnao]⁵: When the teacher says words starting with: a) [ksi]-/Ξ/ ([ksiDi], [ksino], [ksinome] etc.) they pretend they wake up, b) [ksa] - /Ξα/ ([ksana], [ksanarixno] etc.) they pretend they lay down.
	12. I spy with my little eye: child holds a telescope look at something and says the first sound of the word and the others tries to find it.
	13. Prison breaker syllables: Children say their names by clapping their hands or an instrument (each knot corresponds to a syllable). In the next level they have to do the same but by losing a syllable. The rest of the class tries to find which syllable is missing.
	14. Finger Theater: In the thumb children draw a figure and we place one of the target phonemes. On the other fingers we place the vowels. They make the combinations and they try to find words starting with each of them.
	15. Chinese: The teacher reads poems of the phonemes [r] and [l] from Παμπούδη(1981). Then they try all together to say the poems by replacing the [r] by [l] and vice versa.
4 th week	16. Lingo: Children try to place before each syllable the syllable [ksa] or [ra]
	17. The mischief of [kse]: the teacher tells the story of a writer who was writing on a paper but the letters were unwritten ⁶ . At the end children try to continue with their own pairs of words (eg. gr: κουμπώνω-ξεκουμπώνω en: clasp-unclasp/ gr: χτενίζω-ξεχτενίζω en:comb)
	18. Pantomime: Five groups of children. Each group finds a word starting with the target phoneme. They try to explain the word with pantomime to other groups.
	19. Sound-treasure hunt: When the music stops children try to find things starting or including the phoneme that teacher says as fast as possible.
	20. What's in the basket: Children are divided in the group of [l] and in the group of [r]. There is a basket opposite the two groups which contains things that their words start with [l] and[r]. The group that will manage to collect the most things is the winner.
	21. Memo with Pinakoti: In this game a pair of the same cards is needed. The teacher places the pairs promiscuous on the floor and lets the children watch them for a few minutes. Then, turns the cards upside down and children try to find the pairs (all cards are related to the target phonemes).

⁵ /Ξαπλώνω/ en: lay down -/Ξυπνώ/ en: wake up. The phoneme [ks] corresponds to the Greek letter /Ξ/.

⁶The prefix “un” can be ascribed in Greek as “ξε” for example in English is “written”- “unwritten”, in Greek “γραμμένος”- “ξεγραμμένος”.

5 th week	22. Which letter am I?: All children sat in a circle, place a sticker on their forehead with one of the letters of target phonemes. The letter has been chosen from the others. They are saying words starting with different sounds. When they will say the same sound with that in the sticker they win.
	23. Policemen: The teacher tells a story about the syllable thief and tells some words without one syllable and the children try to find them. Some words in Greek are: <i>κουβάγια</i> instead of <i>κουκουβάγια</i> (en: owl), <i>χανίζω/χαχανίζω</i> (en: yawn), <i>λούδι/λουλούδι</i> (en: flower) etc.
	24. Cross the river: Children step on the rocks which are pictures. They select to step on the pictures that their word start or include the sound that the teacher has said.
	25. Words saying, music playing⁷: The child takes a card. Then tries to find another card which makes rhyme. The teacher can use some of the Pinakoti's card to facilitate the children.
	26. Chain: Two children are the start of the chain. Each one chooses one of the target phonemes and says a word starting with it. The others try to find one word starting with one or another phoneme. When a child finds a word says it out loud and runs to the chain of the sound that has been selected. Finally they count which chain has the most children to find the winner.

Table 1 List of the activities of the 5 weeks program

The program starts with an activity which offers the opportunity to the children to introduce themselves. Furthermore, it contributes to the creation of coherence and conditions of good cooperation between the group members. The rest of the program was covered with various types of activities in order to practice children's phonological and phonetic awareness. The second up to the seventh activity are all practicing and strengthening the articulator muscles and were repeated the second week as well. There were activities for teaching letter-sound correspondence (No 8, 21, and 22). There are also activities included for: identifying sounds (No 9, 10, 12, 15, 18, 19, 20, 26), rhymes (No 25), segmentation in syllable level (No 11, 16, 17), deleting syllables (No 13, 23).

There are some activities which combine two or more types, like teaching letter-sound with creating a syllable (No 14) and teaching letter-sound with identifying sounds (No 24).

Most of the activities are suggested by Giannikopoulou (1999) and Gavriilidou (2003:137-185) and they were adjusted to the daily regular program of a Greek public kindergarten. The activities were chosen with a view to be realized by large groups of children. In our case a whole class was taking place in contrast to most intervention phonological programs for preschoolers. Most of them were created to be applied to individual children or to small groups of children (Phillips et al. 2008). Furthermore, Phillips et al. (2008) mentions that the *majority of the studies have included explicit instructional strategies in which the teacher clearly explains, models, and supports children's initial practice with the tasks*. The present training program was presented to the children as daily game and as a small break from the other activities. Thus, the teacher introduces explicit strategies for the phonological and phonetic awareness.

3. Results

The analysis of the data was realized with the non parametric test Man-Whitney U. According to the statistical analysis there was no statistical significant difference in the articulation efforts between the first and the second measure of the experimental group (Table 2).

⁷The title of this activity in Greek can be: *Κάνω μουσική με την πινακωτή*.

Research Groups		N	Mean	Std. Deviation
s1T	control	17	32,12	2,736
	experimental	17	32,53	1,419
s2T	control	17	32,47	2,035
	experimental	17	33,06	,556

Table 2

As well, there was no statistical significant difference between the control and the experimental group in the second measure.

Research Groups		N	Mean	Std. Deviation
m1T	control	17	32,88	2,736
	experimental	17	33,35	1,539
m2T	control	17	33,06	2,358
	experimental	17	33,76	,562

Table 3

There was only an exception where a slight improvement was occurred in the experimental group between the preprogram measure and the post program measure. It seems that students articulated much better the phonemes and the clusters at the beginning of the word after the intervention program (Table 4 and Figure 1).

Descriptive Statistics

	N	Mean	Std. Deviation	Minimum	Maximum
s1T	34	32,32	2,156	23	34
s2T	34	32,76	1,499	27	34
Research Groups	34	1,50	,508	1	2

Table 4

Figure 1 Slight improvement of the experimental group at the first position phoneme and cluster articulation.

4. Discussion

According to the results it is obvious that a training program can affect phonological and phonetic awareness. However, it could be suggested the time extension of the training program considering other training programs such as these of QI, O'Connor (2000) which lasted 10 weeks, Byrne & Barnsley (1991) which lasted 12 weeks and Lundberg et al (1988) which lasted 32 months. That premises the program's enrichment with new activities which should not be daily practiced by children in order to avoid possible undesirable results. Their no constant practice with the program activities may induce positive effects to all levels of phonetic and phonological awareness as they will have more time to absorb the phonetic and phonological skills.

The training program can be flexible and adjusted to the level of the children's phonetic and phonological awareness. The activities are conformed and give the opportunity to the teacher to correct different phonological errors according to the needs of every sample. That renders the training program a useful tool to the teachers. Although, there is no need for particular knowledge of the teacher in order to apply the suggested phonetic-phonological program in the classroom, he/she should be able to recognize the phonetic or the phonological errors. In no case, the program was not created to be a recipe for implementation. The final form that each educational program will take depends on many different factors such as the particular conditions of each school, the student's possibilities, the interests and the priorities of the teachers etc.

Finally, an important parameter that contributed to the no statistical significance of the data analysis could be a consequence of the finite sample. This parameter gives us the motivation to repeat the research and to redefine the results.

5. Perspectives

Due to the lack of statistical significance, this study has to be repeated. Two important parameters that should be considered are the size of the sample and its representativeness. In addition, the duration of the program will be extended as it is suggested above.

In conclusion, our future work will be the enrichment of the GSCC⁸ (Χατζηπαπά 2005). which includes spontaneous speech only. The recordings of the children which were accomplished before and after the intervention program will be added to the extant corpus.

ABSTRACT

This paper presents the EU-funded project KELLY (Keywords for Language Learning for Young and Adults alike) for building corpus-informed vocabulary lists for nine languages: Greek, Arabic, Chinese, English, Italian, Norwegian, Polish, Russian and Swedish. The emerging ranked lists were aligned to the six levels of the Common European Framework of the Council of Europe (A1-C2) and grouped to thematic domains. The methodology employed for constructing the lists is described here, while the focus of the paper is on the application of this methodology in what concerns the Greek language.

Keywords: corpus-informed word lists, L2 learners, vocabulary learning, CEFR, flash-cards

1. Introduction

Until recently vocabulary was not considered one of the priority areas in the field of second language (L2) teaching and was mainly viewed as a secondary activity with the emphasis placed on the development of communicative and linguistic (i.e. grammatical) competence. Nowadays, the primary role of vocabulary in Second Language Acquisition has been acknowledged and vocabulary knowledge is considered indispensable and a prerequisite for acquiring the four traditional language skills (i.e. listening, speaking, reading and writing) as well as grammar: knowing the words of the oral or written input the learners are exposed to enables understanding of discourse, while developing the L2 learner's lexical competence fosters language production.

Lexical competence is a crucial aspect in L2 learning given that successful communication in L2 is interwoven with knowing and deploying the right words to convey the message. According to Nation (2001), language comprehension and production is heavily dependent on vocabulary size, with 3.000 word families being a crucial threshold. A systematic and principled approach in order to build and expand the L2 learners' mental lexicon, therefore, results to better language learning. The crucial question, however, is which words to teach at different language levels.

In this paper we present the EU-funded KELLY project (Keywords for Language Learning for Young and Adults alike) as an innovative effort to address the above issue. The goal of the project was to generate corpus-informed word lists for L2 learners in 9 languages: Greek, Arabic, Chinese, English, Italian, Norwegian, Polish, Russian and Swedish. Based on the lists, sets of bilingual language learning flash cards in many different language combinations comprising the above-mentioned languages will eventually be developed and offered as an on-line vocabulary-building tool in the form of digital bilingual flash-cards. The project was multidisciplinary and comprised experts in language engineering, lexicology, corpus processing, CALL and product development. The consortium consisted of the following partners: Institute for Language and Speech Processing/Athena” R.C. (Greece), Stockholm University (Sweden), Adam Mickiewicz University (Poland), Cambridge Lexicography and Language Services (UK), Italian National Research Council (CNR), Keewords AB (Sweden), Lexical Computing Ltd. (UK), Gothenburg University (Sweden), University of Leeds (UK) and University of Oslo (Norway).

The overall procedure adopted to carry out the above tasks is described in the following sections. After a presentation of the global principles and processes governing all nine languages of the project, the paper focusses on the procedure for the compilation of the Greek lists.

2. The notion of wordlist

Wordlists are considered as a compact (and flat) representation of a corpus in computational linguistics or information theory: they lack much of the information resident in a corpus, but through the simple listing of all the words found in the corpus with their corresponding frequencies, we get a glimpse at the profile of the corpus. Domains such as language production, understanding and acquisition are interested in word frequency, as a word's frequency is related to the speed with which it is understood or learned. In lexicography, frequency lists constitute basic material for the construction of the macrostructure of the dictionary, i.e. the decision which words are to be included. In language teaching, word lists are commonly used in the process of syllabus design and of deciding which words should be included in books teaching children to read, in textbooks for non-native learners, in language tests etc.

From a language learning perspective, word lists and flash cards may be considered as powerful vocabulary-building tools in the context of intentional L2 vocabulary study. A substantial body of research indicates that dedicated vocabulary learning (as opposed to incidental) should have its place in the L2 learning and instructional context, as "there is a very large number of studies showing the effectiveness of such learning (i.e. using vocabulary cards) in terms of the amount and speed of learning." (Nation, 1997). Such studies favour using list and word learning (see for example Schmitt & Schmitt, 1995; Waring, 2004; Mondria & Mondria-de Vries, 1994; Nation, 2001), as the use of the above-mentioned tools exhibits good retention rates (Hulstijn, 2001; Nation, 2001) and faster learning gains. Fostering learner autonomy is an additional argument in favour of the use of word lists and flash cards by L2 learners, since using such tools allows them to work on their own at their individualized pace. Schmitt (1997: 215) notes that "One main advantage of flash cards is that they can be taken almost anywhere and studied when one has a free moment. Another that they can be arranged to create logical groupings of the target words." However, it should be noted at this point that the use of such devices requires motivated and disciplined learners, who should also be able to deploy the right metacognitive strategies required for self-monitoring, planning their own learning etc. As Nakata (2008:7) notes: "If they (learners) cannot monitor their learning accurately and plan their review schedule accordingly, they cannot make the most of word cards and may run the risk of inefficient learning, e.g. over-learning (devoting more time than necessary) of easy items or under-learning of hard items".

3. The methodology adopted

The initial goal was to identify for all nine languages the words that have the highest frequency but at the same time are the most useful for L2 learners. The number of words to be included in the final lists was set to 9,000 per language and the method was decided to be corpus-driven as far as possible. The procedure for preparing the list for each language was as follows:

- Identify the corpus (or corpora) to be used
- Perform a frequency count based on the corpus
- Generate a monolingual frequency list
- Use additional resources to enhance the monolingual corpus-informed lists with words considered essential for language learners per language level
- Translate each item into all the other project languages
- Compare lists and identify items for addition or deletion
- Enrich the monolingual lists by adding words as a result of cross-language comparison
- Provide the final bilingual lists, which were then ranked and aligned to the six CEFR levels (A1-C2)

The above steps were common for all languages; however, as in this paper the focus is on the Greek language, the next sections present this common methodology as applied to the development of the Greek KELLY list.

3.1 Corpus identification

The objective of the endeavour dictated the specifications for the corpus to be selected: it should contain general, everyday language and it should be large with a variety of texts, so that it would not be biased towards any particular text type or topic and would not miss basic vocabulary. An additional specification was for all corpora across languages to be, as far as possible, 'comparable'; in this way, all the lists produced would represent the same kind of language. For some of the languages of the project there was a good choice of corpora available, but not all project languages were equally well served. Spoken corpora were only available for a minority of the languages.

A web corpus provides large bulks of data of general language in a variety of topics and genres. This can be created for any language, using methods as presented in Sharoff (2006). These methods of corpus creation result in corpora that serve the purpose of KELLY better than the BNC-type corpora, which typically have large components of newspaper and fiction, while the predominant language features are past tense verbs, third person pronouns and other prototypical written language features. On the other hand, web corpora are more personal, action-based and future-oriented, and they include more present and future tense verbs, first and second person pronouns, i.e. prototypical spoken language features also. According to Ferraresi et al (2008) there is a better match between CEF *can-do* statements and web corpora, than *can-do* statements and BNC-type corpora.

As regards Greek, two different corpora were used in comparison, with the aim to conduct a comparative study of the frequency wordlists extracted from each type. Specifically:

- Greek Web as a Corpus (GkWaC): a random collection of Greek texts over the web of a size of 41 Million Words, produced in 2010.
- The Hellenic National Corpus (HNC, <http://hnc.ilsp.gr>): 50 Million Words, published between 1990 and 2010, consisting of newspapers, magazines, books (fiction & non-fiction) and miscellaneous texts.

3.2 Generation of the Greek frequency list

The differences in corpus constitution are reflected in the wordlists produced. Thus, since the HNC contains samples of written language exclusively (mainly texts from high circulation newspapers, best-selling books etc., with no idiomatic language), the profile that emerges is that of a higher register, whereas daily/informal speech is largely underrepresented. On the other hand, the GkWaC comprises a variety of sources (news, blogs, chats, etc.) and represents mainly the informal register of everyday speech, approximating spoken language. The steps that were taken to generate the monolingual Greek word list are described below:

Step 1

The corpora were processed with the aim to extract the most frequent words, or rather, the most frequent lemmas, i.e. the canonical forms representing all inflected types. In view of this objective, all three corpora were automatically tokenized, tagged and lemmatized with the respective ILSP tools. The process was fully automatic, with no subsequent manual correction.

Step 2

The subsequent phase included the extraction of frequency lists of the so-called *lemgrams*, i.e. the combinations of lemma and part of speech. The inclusion of the grammatical information on the part of speech was considered necessary in order to have the full identity of a word and to differentiate between cases of the type *ασθενής* (noun) and *ασθενής –ής –ές* (adj.).

Step 3

Unwanted items such as foreign words, hyperlinks, proper names, toponyms etc. were filtered out, since they do not constitute material appropriate to be included in vocabulary learning.

Step 4

At this stage, the lists extracted from each corpus were merged in one.

Step 5

The unified list was checked for duplicates and errors in the lemmatizer and tagger output. In the first case, where a lemma was found in both lists with differing frequency, the item originating in GkWac (and its frequency) was selected; this decision was due to the fact that the web corpus, as already discussed, is more suitable for L2 learners. In the second case of erroneous lemma or part of speech assignment by the automatic procedure, manual inspection of the list and correction of errors was deemed necessary.

For Greek, as for all other languages, the 6,000 most frequent *lemgrams* (lemma+part of speech pairs) were selected during this stage; this was the monolingual list, which served as input to the next process. The inclusion specifications for these 6,000 words comprised the following:

- Spelling variants were amalgamated, so that e.g. αυγό and αβγό [egg] were counted as one word for frequency calculations.
- Inflected forms are not included as such in the list, unless an inflected form has a meaning that is not inherent in the base form, or if the specific word does not follow the rule for lemma, e.g. πρόποδες [foot of the mountain], which is a word lacking the singular number, so the lemma is found in the plural.
- Derivational forms, such as adverbs, deverbal nouns etc., were treated as separate lemgrams.
- Affixes, including productive affixes, were not listed as separate entries.
- The most common abbreviations were listed; these were forms of address, weights and measures and the few cases where an abbreviation is the normal way to refer to an item, e.g. DVD.
- Multi-word units were included, when appearing above the set frequency threshold.
- Phrases, idioms, proverbs, quotations were not included.
- Subject-specific vocabulary (terminology) was not included, except for cases where the term has indeed penetrated general language and is commonly used, e.g. some computer terms.
- Dialectal material was not included, given that the target was the production of vocabulary for the teaching of the norm.
- Items marked by register, e.g. very formal, slang or offensive were subject to the frequency rule: if they appeared in the top 6,000 they were included. However, they were marked as such, to be easily removed if need be.
- Beliefs and religions, as well as associated nouns and adjectives were also subject to the frequency rule.
- Toponyms or proper names (names of stars, planets, place names, river names etc., names of imaginary, biblical or mythological creatures, encyclopedic info such as names of wars, treaties, names of ancient peoples, names of organizations, etc. were not included.

3.3 Enhancing the Greek KELLY list with additional resources

In the KELLY project the idea was to build a list from a web-corpus, which would be a corpus of general everyday language consisting of different texts, so that it would not be skewed by topic-specific texts and thus miss any core vocabulary (taking into consideration the language needs of our target group, i.e. L2 learners). Moreover, given that the objective was to build common lists for 9 languages, an additional constraint was that the corpora in the nine languages should be comparable, i.e. represent the same kind of language, which would allow for making connections between them and thus end up with a common word list for all.

Yet, a purely corpus-derived list on its own may have shortcomings, especially when it addresses L2 language learners: including the most frequent words is not enough. Some words may not exhibit high frequency rates, still they may be necessary to know in the context of L2 learning. “For example, such words as pencil, eraser, and blackboard do not occur in the most frequent words of general English, though they are frequent and essential in a classroom context”. (Schmitt, 2000: 83). Therefore, the additional requirement for the KELLY lists was that they should include the most useful words according to the learner’s language level and, furthermore, these should be in alignment with the CEFR-specific domain vocabulary. In order to meet this additional requirement, available educational resources for the target languages were also consulted.

As far as Greek is concerned, at present there are relatively few vocabulary lists available for Modern Greek, which describe modern vocabulary as well as being adapted to different CEFR levels. The available word lists for Modern Greek that were consulted for the project were the following:

- In a publication issued by the Center for the Greek Language (see Efstathiades et al., 2001) an annex is included with a word list addressing L2 learners of levels A and B (beginners and intermediate) as an annex. The authors label the annex as “Indicative vocabulary for levels A & B” without providing any further information. These lists are not corpus-based and the exact number of lemmas is not specified.
- In the curriculum published by the University of Athens for teaching Modern Greek L2 to adults (University of Athens, 1998), a vocabulary list is included as an appendix. The authors state that the list has been created based solely on their intuition and teaching experience and that the vocabulary listed (which they call “representative vocabulary”) complies with the communicative needs and the learning goals specified in the curriculum and relates to particular notions and functions, speech acts and thematic domains. The number of words is not specified.
- A dictionary for Greek as L2 has recently been released as support material within the framework of the EU-funded programme MiNERA - O.P. Education II – “Educational Project for Muslim Children 2005-2008” (for information see <http://www.museduc.gr/en/index.php>). The dictionary (available at <http://www.museduc.gr/docs/gymnasio/Dictionary.pdf>) includes 10,000 lemmas, which emerged by a processing combination of (i) existing dictionaries of Modern Greek addressed to pupils of primary and secondary education in Greece (as representative for the definition of the “basic/core vocabulary”) and (ii) e-corpora, in which school textbooks were also included. No further information about the corpus is provided.

The Greek corpus-based list was enhanced by manually adding words from the above lists. In particular, the added words belonged to the following thematic domains: animals, fruits, vegetables, colours, family relations, clothes, rooms, furniture, means of transport, shops, doctors and weather.

The fact that certain words that are considered necessary for L2 learners (such as *alphabet*, *elbow* or *orange*) were missing from the corpus-based lists and had to be manually added was not surprising: the lists were derived from general language corpora and not domain-specific or pedagogy-oriented texts. Language coursebooks and L2 curricula, on the other hand, are structured and organized on the basis of communicative situations (e.g. at the super market, shopping, going to the doctor etc.) and relevant vocabulary (e.g. fruits, vegetables, clothes, colours etc.) in compliance with the CEFR-specific domain vocabulary. The overall process for building the Greek monolingual list is depicted in Figure 1 below:

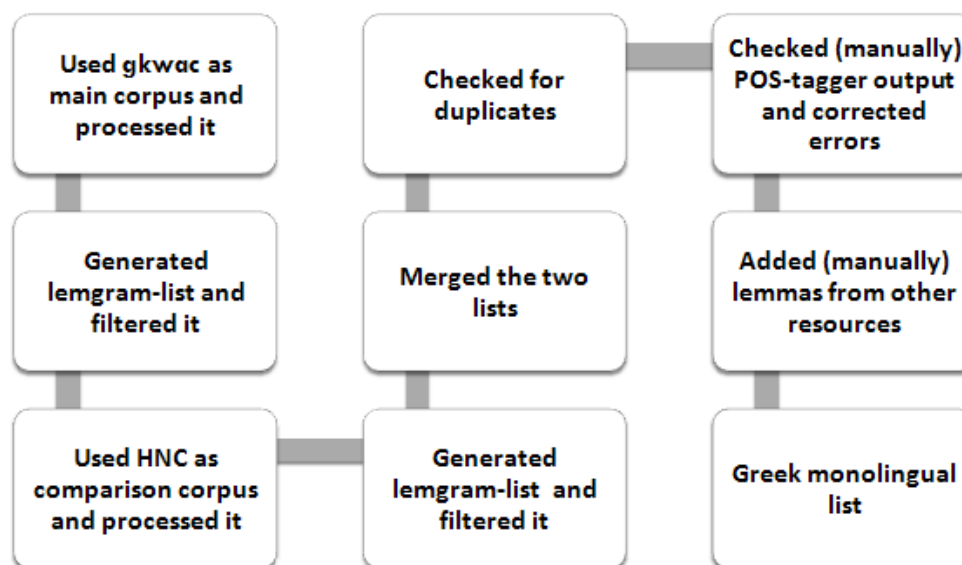

Figure 1 Towards building the Greek monolingual list

3.4 From monolingual to bilingual lists and the KELLY database

The process described above was applied to all other languages and was followed by a cross-language list comparison. The emerging lists were given for translation to all other languages, hence resulting in 72 bilingual lists. Following cross-language comparison, the next step involved handling “back translations” (i.e. words used by translators when translating into a language and not appearing in the monolingual lists of this language) in order to decide which of these should be added to the bilingual lists and which should be deleted or demoted.

The completion of this process rendered the final lists, which consist of approximately 9,000 words per language. These words were ranked according to their frequency range, and were equally distributed to the six CEFR-based language levels (i.e. circa 1,500 words per language level).

The content of the final bilingual lists is hosted by the KELLY database, which contains translation mappings to one or more words in each of the other eight languages. In total, it contains 74,258 lemmas and 423,848 mappings, which renders it an interesting resource that may be accessed and exploited for various research and/or learning purposes. The translations are divided in the following two basic categories:

- (a) Symmetric pairs (*sympairs*): this is a pair of words $\langle a, b \rangle$ of two different languages A and B, such that a translates to b and b translates to a . Table 1 below depicts examples of symmetric pairs across all project languages:

Arabic	Chinese	English	Greek	Italian	Norwegian	Polish	Russian	Swedish
مستشفى	医院	hospital	νοσοκομείο	ospedale	sykehus	Szpital	больница	sjukhus
مكتبة	图书馆	library	βιβλιοθήκη	biblioteca	bibliotek	Biblioteka	библиотека	bibliotek
موسيقى	音乐	music	μουσική	musica	musikk	Muzyka	музыка	music
شمس	太阳	sun	ήλιος	sole	sol	Słońce	солнце	sol
نظرية	理论	theory	θεωρία	teoria	teori	Teoria	теория	teori

Table 1 Example of symmetric pairs

- (b) Non-symmetric pairs (*non-sympairs*): this is the case where in a translation pair $\langle a$ of language A, b of language B, a translates to b but b does not translate to a , although both a and b exist in the respective monolingual lists. For example, in the Greek-English pair the word *μοιράζω* is translated as *distribute*, while in the English-Greek pair the word *distribute* is translated as *διανέμω*. The main reasons for non-sympairs are grouped as follows:

- Linguistic, such as use of different spelling variants, difference in word classes across languages, translators' choices, etc.
- Technical, such as differences in corpus construction, list compilation approaches, lemmatization/normalization problems with resulting difference in item frequency range.
- Cultural differences, which result in the presence or absence of certain vocabulary items.

Apart from the KELLY database, the project will lead to the creation of bilingual flash cards, which in the form of an on-line tool that can be used to enhance vocabulary skills in L2.

4. Summary and outlook

In this paper we have presented the KELLY project and the work carried out towards developing corpus-derived word lists, monolingual and bilingual, for nine languages that may be used and exploited within the L2 teaching and learning framework. We have described in detail the method for the monolingual list creation as regards the Greek language and the steps taken for the creation of the final bilingual lists comprising all nine languages.

The KELLY project constitutes an experiment in using automatic solutions for language learning. In that respect, innovative work has been carried out with respect to the following:

- Innovative methodology was used in order to build frequency-based vocabulary lists from web corpora in nine languages.
- A vocabulary-building tool was created, which may be employed either for self-study purposes or as supplementary material for enhancing vocabulary skills in the context of guided instruction.
- Word lists and flash cards were developed for less widely taught and learned languages and “unusual” language pairs (e.g. Greek-Norwegian, Polish-Italian, Swedish-Arabic etc.).
- A wide spectrum of L2 learners (i.e. young and adults, from beginners to advanced) and learner types was addressed.
- Words were ranked according to the Common European Framework and organized to CEFR-based thematic domains.

Apart from the advantages and innovations, the work carried out within the KELLY project has raised a number of issues which need to be addressed in the future. From a language pedagogy perspective, the crucial question is: how efficient are corpus-informed word lists as pedagogical tools for L2 learning? Is employing purely lexico-statistical approaches to define vocabulary syllabus for L2 learners a safe approach? In other words, can we rely merely on technology and purely objective strategies when it comes to the selection of relevant vocabulary for L2 learners? Even more so, when word lists need to cover the CEFR-related thematic domains and topics?

Future plans for the KELLY outcomes mainly focus on two areas: commercial and linguistic. The commercial dimension involves the creation, sales and marketing of digital bilingual flash cards by the commercial partner of the consortium (Keewords AB). The linguistic part refers to the further exploration of the KELLY database and the evaluation and validation of the KELLY outcomes by the end-users, i.e. actual L2 learners, in order to overcome existing shortcomings and provide a reference tool for vocabulary learning. For less widely used and taught languages (such as Greek) the KELLY lists may prove particularly useful and could be considered, in that respect, a welcome addition.

THE INTERACTION BETWEEN AFFIXES AND BASES: THE CASE OF THE GREEK VERB SUFFIXES

Chariton Charitonidis
University of Cologne, Germany
charitonidis@uni-koeln.de

ABSTRACT

In the first part of this study the semantics of the Greek verb-deriving suffixes -ízo(o), -én(o), -év(o), -ón(o), -(i)áz(o), and -in(o) are presented. The description is based on an empirical analysis of data extracted from 28 interviews conducted with native speakers of Greek, in Athens, Greece. In the analysis Rochelle's Lieber's (2004) theoretical framework is used. In the second part are presented the properties of an interfering socio-expressive level of meaning, i.e. the 'socio-expressive tier', on the example of -(i)áz(o) verbs. The analysis suggests the coordination of Lieber's denotational structures with the author's socio-expressive structures so that a base can be selected by a particular suffix.

Keywords: verb suffixes, morphological theory, lexical semantics, socio-expressive meaning

1. Introduction

Efthymiou (2011) dealt with the semantics of the verb-forming suffixes -ízo, -(i)ázo, -óno, -évo and -éno in Modern Greek (MG).¹ She used the following labels to describe their meaning: RESULTATIVE (turn into x, make (more) like x; cf. *mavrízo* 'cause to) become black, blacken' (*mávros* 'black')), INCHOATIVE (become x; cf. *skulikíazo* 'be wormy/wormeaten' (*skuliki* 'worm')), ORNATIVE (provide with x; cf. *vutiróno* 'to butter' (*vútiro* 'butter')), LOCATIVE (put in(to) x; cf. *tsepóno* 'to pocket' (*tsépi* 'pocket')), PERFORMATIVE (perform/do/make x; cf. *taksidhévo* 'to travel' (*taksídi* 'travel')), SIMILATIVE (do/make/act in the manner of/like x; cf. *pithikízo* 'imitate ape's behaviour, to ape' (*píthikos* 'ape')), and INSTRUMENTAL (use x; cf. *nixíazo* 'scratch with one's nails' (*níxi* 'nail')). Table 1 summarizes Efthymiou's analysis.

	-ízo	-(i)ázo	-óno	-évo	-éno
RESULTATIVE	✓	✓	✓	✓	✓
INCHOATIVE	✓	✓	✓	✓	✓
ORNATIVE	✓	✓	✓	✓	✓
LOCATIVE	✓	✓	✓	✓	
PERFORMATIVE	✓	✓		✓	
SIMILATIVE	✓	✓		✓	
INSTRUMENTAL	✓	✓	✓	✓	

Table 1 The semantics of the native Greek verb suffixes [Efthymiou 2011]

As Efthymiou (2011) notes, the meanings of -óno and -éno are more restricted than the meanings of -ízo, -(i)ázo, and -évo, and all suffixes seem to share a common causative/resultative meaning (see Table 1). Accordingly, she proposes the semantic structure CAUSE [x BE y LOC z] for all denominal and deadjectival verbs in MG.

Efthymiou's (2011) analysis revealed many overlaps in the selectional properties of the suffixes, but also in the phonological shape of the bases onto which they attach. For example, both -óno and -évo prefer nominal bases, both -ízo and -(i)ázo prefer nominal and adjectival base stems which end in a consonant, etc.

¹ The suffix -ino was not examined by Efthymiou (2011). Her analysis for the suffix -áro and for the confix -pió is not relevant for this study. The former has a strong preference for nominal bases of non-Greek origin, the latter has an unclear status. Verb forms and endings are given together with the inflectional ending -o in the first person singular – the standard citation form for Greek verbs.

Charitonidis (2011) conducted four language experiments with 28 native speakers of Greek in February 2009, in Athens, Greece. His main goal was to detect the semantic profile of the native Greek verb suffixes *-ízo*, *-éno*, *-évo*, *-óno*, *-(i)ázo*, and *-íno*. The experiments had the form of four interview tasks referring to predictions and evaluations as regards *lexical* knowledge. This means that no context was given together with the tested material.

In the first two tasks were examined the effects of online combination of bases and suffixes under the condition of forcing, irrespective of output restrictions, e.g. blocking, etc. (Plag 1999). The other two tasks referred to existing/established verbs. In the analysis of the elicited data Lieber's (2004, 2007) theoretical framework was used. The comparison of the patterns in created verbs with the patterns in existing/established verbs validated the former.²

The present paper is within the scope of the project "The Integration of Socio-expressive Meaning into Verb Structures" conducted by the author at the University of Cologne, Germany.

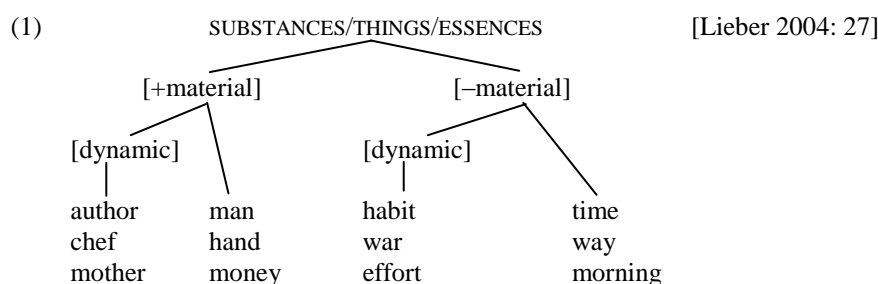

2. Theoretical framework

The great advantage of Lieber's (2004, 2007) model is the efficient handling of transpositional effects between a derivative and its base on a semantic basis. Affixes are regarded as linguistic signs equivalent to the bases onto which they attach (the sign-based hypothesis; see Plag 1999, 2000, Melissaropoulou & Ralli 2010). They operate on bases, while producing a derivative which is allocated to the same set of featural combinations as the bases themselves. According to Lieber (2004: 9–10) there is a fundamental distinction in the lexical semantic representations of lexical items: the Semantic/Grammatical Skeleton (*skeleton*, for short) and the Semantic/Pragmatic Body (*body*, for short). The skeleton seeks to isolate "all and only those aspects of meaning which have consequences for the syntax", while the body is "encyclopedic, holistic, nondecompositional, not composed of primitives, and perhaps only partially formalizable".

Lieber (2004) defines two conceptual categories (major ontological classes) for the skeletons: SUBSTANCES/THINGS/ESSENCES and SITUATIONS. These categories are used as mnemonic labels for different combinations of semantic features, and not as primitives. The very essence of her system is formed by the features [material] and [dynamic]. These features can be positive or negative, whereas in the case of nominal forms, the feature [dynamic] may be totally absent (see (1) below).

As regards the decomposition of the major lexical categories by means of features, Lieber assumes that nouns have at least the feature [material] in their skeleton, verbs and adjectives have the feature [dynamic] without the feature [material], verbs may be [+dynamic], i.e. EVENTS, or [–dynamic], i.e. STATES. Adjectives bear the feature [–dynamic], i.e. they are STATES. In Lieber (2007) the features [+scalar] and [–scalar] for adjectives are introduced, cf. the adjectives *wide* and *pregnant*, respectively.

The system of SUBSTANCES/THINGS/ESSENCES is found in (1).

The semantic features presented so far are used as functions which take arguments. Lexical items will always have at least one argument – in the case of nouns at least one argument called "R"-argument (referential argument) – but they may also have more than more argument, see (2) below.

- (2) *leg* [+material ([], [])] (e.g. *the leg of the table*) [Lieber 2004: 25]
fond [–dynamic ([], [])] (e.g. *fond of pickles*)
kiss [+dynamic ([], [])] (e.g. *kiss frogs*)

² The analysis and the results in Charitonidis (2011) are presented in sections 3 and 4, respectively.

Created using Microsoft Excel 2003
Figure 1 Bases and suffixes in interaction

3.2 Evaluation of created derivatives

In the second task the TPs were asked to evaluate three groups of forced verbs with a noun, an adjective, and an adverb, respectively, by using one (best/highly acceptable verb) to six (worst/unacceptable verb) points. The aim of this task was to detect the selectional properties of the suffixes in relation to the lexical category of the base. The averages are given in Table 3.³

N <i>potíri</i> 'glass'	Average	A <i>xlorós</i> 'green', 'unseasoned'	Average	ADV <i>káto</i> 'down'	Average
!potirízo	3.86	!xlorízo	2.96	!katízo	3.93
!potirévo	4.04	!xlorévo	3.50	!katévo	3.82
!potiréno	4.21	!xloréno	2.29	!katéno	3.54
!potiróno	2.39	!xloróno	3.93	!katóno	3.68
!potiriázo	3.64	!xloriázo	3.25	!katiázo	3.57
!potiríno	5.39	!xloríno	4.25	!katíno	4.68
Mean	3.92	Mean	3.36	Mean	3.87

Table 3 Evaluation of created derivatives

3.3 Detection of differences in verb doublets (existing/established verbs)

In the third task 19 existing/established verb pairs with different suffixes and the ending -áo/-ó were presented. All pairs contained one verb in -ízo. The TPs were asked to report whether there was some difference between the members of the pairs and what exactly this difference was. The differences reported were transformed into 16 alternations. The alternations most relevant for the present study are given in Table 4 together with examples.

Alternations	Rival endings	Example verbs	Base
literal/similative (6)	-iázo vs. -ízo	<i>maniázo</i> vs. <i>manízo</i> 'get angry'	<i>manía</i> 'mania', 'fury', 'anger'
semelfactive-simple/ habitual (8)	-ízo vs. -áo/-ó	<i>serghianízo</i> vs. <i>serghianáo</i> 'take so./go for a walk'	<i>serghiani</i> 'walk'
non-intensive/intensive (9)	-áo/-ó vs. -ízo	<i>stúbáo</i> vs. <i>stúbízo</i> 'pestle'	<i>stúbos</i> 'pestle'
non-fullness/fullness (10)	-ízo vs. -iázo	<i>luludhízo</i> vs. <i>luludhiázo</i> 'flower', 'blossom', 'bloom'	<i>luludhi</i> 'flower', 'blossom', 'bloom'

³ In the present study creations are indicated with '!'.

more/less (phonologically) aesthetic/correct (12)	-ízo vs. -iázo	<i>kitrinízo</i> vs. <i>?kitriniázo</i> 'become yellow/pale'	<i>kítrinos</i> 'yellow/pale'
standard/low class- provincial (16)	-ízo vs. -áo/-ó	<i>kutsulízo</i> vs. <i>kutsuláo</i> 'throw droppings', 'dirty with droppings'	<i>kutsuliá</i> 'droppings' (dung of an animal)

Table 4 Alternations in verb doublets

3.4 Emergence of suffix meanings in (near) antonyms (existing/established verbs)

In the fourth task 21 existing/established verbs with different suffixes were presented. The TPs were asked to give the "opposite" or "near opposite" expression for each verb. The rationale behind this task was to arrive at the meaning of the suffixes through the meaning of the opposites. For example, a feature [+dynamic] was assigned to -évo according to the TP response *káno to sostó* 'do the right thing' for *lathévo* 'be at fault' (*láthos* 'error', 'wrong'), etc.

3.5 The suffix features used in the analysis

Table 5 contains the most relevant features used in the analysis of the elicited data. Denotational (DE) features are enclosed in square brackets, and socio-expressive (SE) features in curly brackets. Features 1–4 directly correspond to Lieber's (2004, 2007) DE features and are adopted as such. Features 5–7 are mnemonic labels for extra DE structures emerged from the analysis. Features 8–15 are SE features introduced by the author.

	Feature	Meaning	Example endings	Example verbs
1.	[+dynamic]	Event	-ázo	<i>!leftázo</i> 'make money' (<i>leftá</i> 'money')
2.	[–dynamic]	State	-évo	<i>!mitérévo</i> 'be a mother' (<i>mitéra</i> 'mother')
3.	[+dynamic, +IEPS, +Loc]	Unaccusative/inchoative	-éno	<i>!mitéréno</i> 'become a mother' (<i>mitéra</i> 'mother')
4.	[–dynamic, +Loc]	Location or end of a change of state/end of a transfer	-évo	<i>!proinévo</i> 'be in the morning time' (<i>proινό</i> 'morning')
5.	[+accumulation] ('fullness' in section 3.3)	Accumulation of some referent in the described event/state	-iázo	<i>!lexiázo</i> 'be a materialist', 'want many things' (<i>éxo</i> 'have')
6.	[+habitual] (TP comment)	Habitual action	-áo	<i>serghianáo</i> 'take so./go for a walk' (<i>serghiani</i> 'walk')
7.	[+similative]	Similarity of the behaviour of an individual to that of another individual (usually denoted by the base)	-ízo	<i>!miterízo</i> 'behave like a mother' (<i>mitéra</i> 'mother')
8.	{+aesthetic/correct} (TP comment)	Aesthetic/correct form	-ízo	<i>kitrinízo</i> 'become yellow' (<i>kítrinos</i> 'yellow')
9.	{–aesthetic/correct} (TP comment)	Non-aesthetic/incorrect form	-iázo	<i>?kitriniázo</i> 'become yellow' (<i>kítrinos</i> 'yellow')
10.	{+derisive} (TP comment)	Derisive use	-iázo	<i>?kitriniázo</i> 'become yellow' (<i>kítrinos</i> 'yellow')
11.	{+diminutive}	Small referent	-ízo	<i>!troghízo</i> 'eat a small amount' (<i>trógho</i> 'eat')
12.	{+evaluation} ⁴	Positive evaluation	-évo	<i>taksidhévo</i> 'journey', 'travel' (<i>taksidhi</i> 'journey', 'travel')
13.	{–evaluation}	Negative psychology, pejorative meanings, and negative ethical views	-iázo	<i>!miteríázo</i> 'behave annoyingly like a mother' (<i>mitéra</i> 'mother')

⁴ In Charitonidis (2011) {+evaluation} was assigned only to -évo according to the meaning of existing antonymous verbs (see Charitonidis 2011: 28). More experiments should be made to validate this feature.

14.	{+intensive} (TP comment)	Intense activity	-ízo	<i>serghianízo</i> 'take so./go for a walk' (<i>serghiáni</i> 'walk')
15.	{+low class/provincial}	Low class/provincial form	-áo	<i>kutsuláo</i> 'throw droppings', 'dirty with droppings' (<i>kutsuliá</i> 'droppings')

Table 5 Features for suffixes/endings

4. Results

The repetition of a pattern in at least two interview parts introduces a feature or feature cluster for each suffix. As an exception, special focus is placed on the alternations of section 3.3, which introduces several features. Table 6 summarizes the results of the analysis.

	[+dynamic]	[-dynamic]	[+dynamic, +IEPS, +Loc]	[+dynamic, +simulative]	[+accumulation]	[+habitual]	{+intensive}	{-evaluation}	{+low class/provincial}
-ízo	✓ ^a		✓ ^b	✓ ^c			✓ ^d		
-éno	✓ ^e		✓ ^f						
-évo	✓ ^g	✓ ^h	✓ ⁱ						
-óno	✓ ^j		✓ ^k						
-iázo	✓ ^l		✓ ^m		✓ ⁿ			✓ ^o	
-íno			✓ ^p						
-áo/-ó						✓ ^q			✓ ^r
Sections	^a 3.1, 3.4 ^j 3.1, 3.4	^b 3.1, 3.4 ^k 3.2, 3.4	^c 3.1, 3.3 ^l 3.1, 3.4	^d 3.3 ^m 3.1, 3.4	^e 3.1, 3.4 ⁿ 3.1, 3.3, 3.4	^f 3.1, 3.4 ^g 3.1, 3.4	^h 3.1, 3.4 ^p 3.1, 3.4	ⁱ 3.1, 3.4 ^q 3.3	^r 3.3

Table 6 The meaning of the native Greek verb suffixes and the verb ending -áo/-ó

The features ticked off for -áo/-ó represent only suggestions. The restricted number of the TP reactions and the regional/dialectal character of this ending⁵ do not allow further generalizations.

4.1 The results regarding denotational (DE) meaning

As can be seen in Table 6, the suffixes are not very different from one another. To show this more clearly, I give Lieber's (2004) bipartite structure for the English verb derivatives in -ize and -ify in (see (5)).

- (5) -ize, -ify [Lieber 2004: 82]
 [+dynamic ([_{volitional-i}], [_j])] ; [+dynamic ([_i], [+dynamic, +IEPS ([_j], [+Loc])))] ; <base>

In Table 6 the cluster [+dynamic, +IEPS, +Loc] shows up most often across the different suffixes. This cluster corresponds to the subevent (6), extracted from the structure in (5).

- (6) [+dynamic, +IEPS ([], [+Loc])]

The crucial semantic core [+dynamic, +IEPS ([], [+Loc])] in (6) shows that on the level of DE meaning the suffixes are similar. The pattern [+dynamic] in Table 6 can be regarded as an extension of this core connected with various manipulations of the bipartite structure in (5) – cf. Lieber (2004: 86–88). It should be noticed, however, that simple [+dynamic] is not a preferred option for the suffix -íno which resists manipulations of its causative structure. Suffix -óno has a strong [+Loc] component, i.e. it standardly combines with [+material] themes (see sections 3.1 and 3.2).

⁵ -áo is characteristic of southern – mainly Peloponnesian – dialects. In certain northern Greek dialects, only the -ó variant exists (see also Melissaropoulou 2010).

The feature [+habitual] for *-áo/-ó* in Table 6 is too broad a feature to be integrated in Lieber's system, since its classifying power and hence its contribution to the identification of referents is restricted (see section 2).

The feature [+accumulation] for *-iázo* in Table 6 is represented in Lieber's system through the function [+CI] ('composed of individuals') which accounts for separable similar internal units (see Lieber 2004: 136–139).

The cluster [+dynamic, +similative] for *-ízo* in Table 6 corresponds to the first subevent of (5) whereby the referent of the base shows up in the first slot (see Lieber 2004: 87–88).

Up to this point, Lieber's system properly accommodates the DE content of the Greek verb suffixes. It should be noted, however, that the [–dynamic] and [+dynamic] patterns of *-évo* in Table 6 are the strongest argument against a single, perhaps bipartite, structure like this in (5), because contradictory outermost features are not licensed in Lieber's system.

4.2 The results regarding socio-expressive (SE) meaning

Let us now turn to the SE features of Table 6. The feature {+intensive} is a relational feature which emerged out of the comparison of the suffix *-ízo* with the ending *-áo/-ó* (section 3.3). I assume that the rest of the suffixes relate to this feature as well. According to the analysis in section 5 below, {+intensive} is subsumed under the super-category {+measure} (see Table 7).

{–evaluation} for *-iázo* in Table 6 is a powerful selectional feature. The entities which can occupy the empty slots in structure (5) are nominal [+material, dynamic] agents (the first argument of the first partial structure) or adjectival [–dynamic, +scalar] goals (the [+Loc] argument). However, {–evaluation} cuts across these categorial and structural preferences. It prefers {–evaluation} bases such as the [+material, dynamic] entity *rébelos* 'loafer' in *rebeliázo* 'loaf' or the [–dynamic, –scalar] entity *paráksenos* 'odd' in *parakseniázo* 'grow odd' (see section 6).

In addition, I would like to underscore some selectional patterns emerged from the analysis in section 3.1. *-ízo* is a similative suffix and because of this it prefers entities referring to a social role, such as *mitéra* 'mother'. *-évo* is often used with nominal bases denoting a specific social role, esp. a profession or an office (Efthymiou 2011). This SE preference is capable of changing the [+dynamic] structure of *-évo* into [–dynamic]. *-iázo* conflicts with socio-expressively neutral bases, such as *adhikía*, since it is negatively marked (see Table 2 and Fig. 1).

To conclude, the patterns presented in this section suggest a major interference of the SE level of meaning with Lieber's (2004) DE structures. Both levels of meaning must be addressed in order to account for the selectional properties of the suffixes and hence for productivity.

5. The socio-expressive (SE) tier

In Charitonidis (2011) a group of interfering SE components in the structure of the verb suffixes were detected, e.g. {±evaluation}, {±aesthetic/correct}, {+derisive}, {+diminutive}, etc. (see Table 5). In Table 7 I introduce a set of features which formalize the SE level of meaning – the motivation of the features can be found in Charitonidis (2012).

{+m}	Meaning of measurement/continuation/progress, i.e. size, intenseness, strength etc., of a higher (cf. {+intensive}) or lower (cf. {+diminutive}) degree	{–m}	Invariable SE content
{+s}	Positive stance towards a situation or entity	{–s}	Negative stance towards a situation or entity
{+i}	Estimations and stances explicitly involving the domain of interpersonal relations	{–i}	Estimations and stances that are to a certain degree orthogonal to the domain of interpersonal relations

Table 7 The SE features and their meaning

According to Efthymiou's (2011, submitted) analysis and the results in the previous section, the percolation of the [–learned] feature of *-(i)ázo* to the output verbs and the preference of this suffix for

negatively marked bases, suggest a coordinative structure for the *-(i)ázo* derivatives in which both suffixes and bases are marked negatively.⁶

The SE patterns of *-(i)ázo* detected in Charitonidis (2011) are given in Table 8. '[TP]' refers to a direct TP comment.

SE components (suffix)	SE features (suffix)	Verbs	Bases
{-evaluation}, {+derivative} [TP], {-aesthetic/correct} [TP]	{+m}, {-s}, {i}	? <i>kitriniázo</i> 'become yellow/pale'	<i>kítrinos</i> 'yellow', 'pale'
{-evaluation}	{+m}, {-s}, {i}	! <i>potiriázo</i> 'I fume at/over having washed a lot of drinking glasses'	<i>potíri</i> 'glass'

Table 8 The SE patterns of the Greek verb suffix *-(i)ázo*

In the interviews ?*kitriniázo* was juxtaposed with the existing/established verb *kitrinízo* which did not received negative evaluations. Accordingly, the {-s} feature was assigned to the suffix *-(i)ázo* and not to the body of the ADJ *kítrinos*. The same argument holds for !*potiriázo* which was juxtaposed with creations having the same base but different suffixes.

After considering the interpretations and evaluations of all created and existing verbs in Charitonidis (2011) we arrive at two main SE clusters for the Greek verb suffixes. These are given in (7).

- (7) {+m}{s}{i} default SE matrix for *-ízo, -éno, -évo, -óno, -íno*
 {+m}{-s}{i} default SE matrix for *-(i)ázo*

The SE features in (7) would be ad hoc conceptions, if they could not sufficiently explain the combinatorial properties of the suffixes in existing derivatives and creations. In (8) I give the combinatorial system of these features.

(8) The properties of the SE tier in relation to verb suffixation

- Derivation bases refer to the same set of features as suffixes, i.e. {m},{s}, and {i}.
- Suffixes are compound heads. Their valued features are also heads.
- Underdetermined features are merged regardless of their head role.
- The base arguments are addressed by the features throughout the derivation, i.e. the base arguments are evaluated anew in every derivational step including output.

Up to this point, the atoms of the SE tier and their combinatorial properties were presented. What we now need to validate this system are exemplifying SE operations in existing verbs, neologisms, and creations. This task is accomplished in the next section on the example of *-(i)ázo* verbs.

6. Application

In the analysis to follow I present three cases of derivation which cover an acceptability continuum, i.e. existing/established verbs, fresh neologisms, and forced verbs. In doing so, I assume a tripartite template, in which bases, suffixes, and output verbs refer to the same set of features, i.e. {m},{s}, and {i}.

6.1 Deadjectival [-dynamic, -scalar] verbs in *-(i)ázo*

The deadjectival [-dynamic, -scalar] verbs in *-(i)ázo* found in the Reverse Index of Modern Greek (RIMG) are given in Table 9. As can be seen {+m}{-s}{-i} bases are preferred by *-(i)ázo*.

⁶ In Efthymiou (submitted) the preference of *-(i)ázo* for negatively marked bases is mentioned, together with its capability to place a negative interpretation on derivatives whose bases are not negatively marked, cf. *thróniázo* 'enthroned' (ironically; *thrónos* 'throne'), etc.

Verb		Base		SE cluster (base)
<i>alaliázo</i>	'daze', 'drive sb mad'	<i>álalos</i>	'stunned', 'dazed'	{+m}{-s}{-i}
<i>anapodhiázo</i>	'become cantankerous/ 'crabby'	<i>anápodhos</i>	'cantankerous', 'crabby'	{-m}{-s}{+i}
<i>apagiázo</i>	'offer/find shelter from the weather'	<i>apágio</i>	'lee[ward]'	{-m}{+s}{-i}
<i>blaviázo</i>	'become dark blue'	<i>blávōs</i>	'dark blue'	{+m}{-s}{-i}
<i>kaburiázo</i>	'become/be hunch- backed/hump-backed'	<i>kabúris</i>	'hunch-backed', 'hump-backed'	{+m}{-s}{-i}
<i>kakomiriázo</i>	'become wretched/ miserable', 'have a bad time'	<i>kakomiris</i>	'wretched', 'miserable'	{+m}{-s}{-i}
<i>kluviázo</i>	'get addled', 'grow addled- headed'	<i>klúvios</i>	'addled', 'addled headed'	{+m}{-s}{-i}
<i>ksefreniázo</i>	'become frenzied/furious'	<i>kséfrenos</i>	'frenzied', 'furious'	{+m}{-s}{+i}
<i>ksethoriázo</i>	'fade'	<i>kséthoros</i>	'faded'	{+m}{-s}{-i}
<i>neruliázo</i>	'grow watery', 'grow flabby'	<i>nerulós</i>	'watery', 'flabby'	{+m}{-s}{-i}
<i>parakseniázo</i>	'grow odd'	<i>paráksenos</i>	'odd'	{-m}{-s}{+i}
<i>varvatiázo</i>	'rut', 'be in heat'	<i>varvátos</i>	'virile', 'in heat'	{+m}{+s}{-i}
<i>vathuliázo</i>	'become hollow', 'sag'	<i>vathulós</i>	'hollow'	{+m}{-s}{-i}

Table 9 Existing *-(i)ázo* verbs with an adjectival [–dynamic, –scalar] base [RIMG; approx. 19c.–]

By way of example, the SE structure of *alaliázo* is given in (9).

(9) *álalos* 'stunned', 'dazed' > *alaliázo* 'daze', 'drive sb mad'

<i>álalos</i>	<i>-(i)ázo</i>	<i>alaliázo</i>
{+m}	{+m}	{+m}
{-s}	{-s}	{-s}
{-i}	{i}	{-i}

As can be seen, the features {+m}{-s} in both the base and in the suffix suggest a coordinative structure for *alaliázo*.

In (10) the SE structure of the very fresh neologism *?kitriniázo* is given.

(10) *kítrinos* 'yellow/'pale' > *?kitriniázo* 'become yellow/pale'

<i>kítrinos</i>	<i>-(i)ázo</i>	<i>?kitriniázo</i>
{-m}	{+m}	{+m}
{-s} ✓pref	{-s}	{-s}
{-i} ✓pref	{i}	{-i}

As can be seen in (10), the base *kítrinos* addresses two of the three features in the preferred base structure of the existing verbs (compare *kítrinos* with the verb bases in Table 9). This must be the reason why *?kitriniázo* is for some native speakers of Greek ungrammatical.⁷ As regards the TP interpretation 'become yellow/pale' for *?kitriniázo*, this very fresh neologism is motivated by a degradation of the properties of *kítrinos*, i.e. the referent acquires a hue close to the focal colour YELLOW (cf. Berlin & Kay 1969). It should be noted that the output cluster {+m}{-s}{-i} in *?kitriniázo* is identical with the preferred base cluster in the existing verbs (compare (10) with (9)).

6.2 Denominal [+material, dynamic] verbs in *-(i)ázo*

The denominal [+material, dynamic] verbs in *-(i)ázo* found in RIMG are given in Table 10. As can be seen {+m}{-s}{+i} bases are preferred by *-(i)ázo*.

⁷ In this case the rival form *kitrinízo* having a more neutral meaning is preferred (cf. Table 5).

Verb		Base		SE cluster (base)
<i>bekruliázo</i>	'be on the booze'	<i>bekrís</i>	'drunkard', 'boozier'	{+m}{-s}{i}
<i>kubariázo</i>	'become the best man of sb'	<i>kubáros</i>	'best man'	{-m}{+s}{+i}
<i>lighuriázo</i>	'feel craving for'	<i>lighúra/lighúris</i>	'craving'/'sharp-set'	{+m}{-s}{i}
<i>papardheliázo</i>	'blabber'	<i>papardhélas</i>	'blabbermouth'	{+m}{-s}{+i}
<i>papudhiázo</i>	'wrinkle' – esp. for hands or feet after having been a long time in water	<i>papúdhi</i>	'granddad', 'old man'	{+m}{s}{+i}
<i>rebeliázo</i>	'loaf'	<i>rébelos</i>	'loafer'	{+m}{-s}{+i}

Table 10 Existing *-(i)ázo* verbs with a nominal [+material, dynamic] base [RIMG; approx. 19c.–]

By way of example, the SE structure of *rebeliázo* is given in (11).

- (11) *rébelos* 'loafer' > *rebeliázo* 'loaf'
- | | | |
|----------------|----------------|------------------|
| <i>rébelos</i> | <i>-(i)ázo</i> | <i>rebeliázo</i> |
| {+m} | {+m} | {+m} |
| {-s} | {-s} | {-s} |
| {+i} | {i} | {+i} |

As in the case of *alaliázo* in (9), the features {+m}{-s} in both the base and in the suffix suggest a coordinative structure for *rebeliázo*.

In (12) the SE structure for the creation *!miteriázo* is given.

- (12) *mitéra* 'mother' > *!miteriázo* 'behave annoyingly like a mother'
- | | | |
|---------------|----------------|------------------|
| <i>mitéra</i> | <i>-(i)ázo</i> | <i>miteriázo</i> |
| {-m} | {+m} | {+m} |
| {+s} | {-s} | {-s} |
| {+i} ✓pref | {i} | {+i} |

As can be seen, the base *mitéra* addresses only one of the three features in the preferred base structure of the existing verbs. This must be the reason for the forced character of the creation *!miteriázo* (compare *mitéra* in (12) with the verb bases in Table 10). As regards the TP interpretation 'behave annoyingly like a mother' for *!miteriázo*, the creation is motivated by an intensification of the properties of the mother which leads to a negative stance towards her.⁸ It should be noted that the output cluster {+m}{-s}{+i} in *!miteriázo* is identical with the preferred base-cluster in the existing verbs (compare (12) with (11)).

7. Conclusion

The analysis in this paper suggests (i) a sign-based treatment of affixes, (ii) a vertical preference structure in the semantic structure of the head suffixes which takes into account the semantic make-up of the bases, and (iii) the integration of SE meaning into verb structures. Sections 5 and 6 showed that the formalization of bodily structures by means of SE features is feasible, contrary to Lieber's (2004) assumptions. In the case of the deadjectival and denominal verbs in sections 6.1 and 6.2, respectively, {+m}{-s}{±i} bases are preferred by *-(i)ázo*. The DE clusters [-dynamic, -scalar] for ADJs and [+material, dynamic] for Ns are too general to account for this preference and would over-generate verbs. This is obviously a consequence of their syntactic motivation (see section 2). For example, we have *kluviázo* 'get addled', 'grow addled-headed' derived from the {+m}{-s}{-i} ADJ *klívios* 'addled', 'addled headed' but not **iperoxiázo* having as base the {+m}{+s}{i} ADJ *ipéroxos* 'excellent'. Similarly, we have *rebeliázo* 'loaf' derived from the {+m}{-s}{+i} N *rébelos* 'loafer' but not **ghoitiázo* having as base the {-m}{+s}{+i} N *ghóis/ghóitas* 'charmer'.⁹

To conclude, it seems that we need both a DE and an SE tier in accounting for verb derivation. The DE tier relates to syntax and the identification of referents, whereby the inner-word structure is grossly

⁸ The implicational nature of this pattern should be examined in future research.

⁹ I assign {-m} to *ghóis/ghóitas* because charm cannot be thought of as a scalar or derived property. It should be noted that in Modern Greek the established verb *ghoitévo* 'fascinate' is in everyday use. This verb has no negative connotations.

addressed. The SE tier restricts the syntactically motivated patterns so that bases with a specific semantic composition can be selected by a particular suffix.

ABSTRACT

*The goal of this study is to test experimentally two hypotheses about NPIs and universal quantifiers in Greek and their scopal interaction with negation. The first hypothesis emerges from the claim that Greek ‘emphatic’ NPIs are NPI-universals that take scope above negation (Giannakidou 1998, 2000, 2006). In this theory, emphasis (i.e. pitch accent) on the NPI functions as morphological marking that distinguishes lexically the NPI-universal from its non-emphatic counterpart which is licensed broadly as an existential quantifier in non-veridical contexts (and is parallel to any). The second hypothesis is that intonation in Greek generally marks wide scope of a quantifier above negation (Giannakidou 1998, 2000, Baltazani 2002). To test these hypotheses we set up a task that requires subjects to map emphatic and non-emphatic intonations onto scenarios with total (wide scope universal) and partial negation (narrow scope universal with respect to negation). We find that subjects uniformly choose the wide scope universal scenario for emphatic NPIs, suggesting indeed a robust association of the NPI-construal with wide scope, as predicted by Giannakidou’s theory. We find, however, more variable judgments with the universal quantifier *oli* ‘all’, suggesting that the second hypothesis, namely that emphatic intonation signals wide scope with respect to negation, is less robust. The difference between our two findings suggests may be taken to reflect a difference between morphological marking and scope marking, which applies at the level of prosody.*

1. Background: emphatic and non-emphatic NPIs in Greek

Greek has two NPI paradigms, distinguished by ‘stress’ (Veloudis 1982, Giannakidou 1997 et seq., Tsimpli and Roussou 1996):

(1)	kanénas/KANÉNAS	‘anyone, anybody/no-one, nobody’
	kanénas N/KANÉNAS N	‘any N/no N’
	típota/TÍPOTA	‘anything/no thing’
	poté/POTE	‘ever/never’
	puthená/PUTHENA	‘anywhere/nowhere’
	kathólu/KATHOLU	‘at all/not at all’

Upper-case letters indicate emphatic accent. *Kanénas* is the masculine, *kamía* is the feminine, *kanéna* is the neuter. Since Veloudis’s original observation, the two paradigms have been treated as distinct because they exhibit systematic differences in distribution, interpretation and overall behavior, a brief summary of which we give below. The accent is not indicative of focus movement for reasons that have been discussed elsewhere (Giannakidou 1997, and 1998, pp. 227–231). Giannakidou 1998, 2000 notes that other quantifiers, e.g. *polí* ‘much’ and *líji* ‘few’ also come in emphatic and non-emphatic variants corresponding to lexical contrasts in English, and suggests to handle the emphatic NPIs as lexically distinct from the non-emphatic ones. Emphatic accent therefore functions as a morphological marking that Greek appears to employ more broadly.

Under negation and antiveridical *without* both paradigms are licensed:

- (2) a. Dhen idhe {típota/TÍPOTA} o Jánis. Greek
not saw anything the John
John didn't see anything.
b. * Idhe {típota/TÍPOTA} o Jánis.
John saw anything.
- (3) xoris na dhi {kanénan/KANÉNAN}.
without subj see.3sg n-person
without having seen anybody.

So, both paradigms— emphatic and non-emphatic— are NPIs and need negation. But the two differ in a number of important respects:

(i) *Fragment answers*

Only the emphatic can give a successful fragment answer:

- (4) - Pjon idjes? “Who did you see?”
- {KANÉNAN/*kanénan}
Nobody/*Anybody.

The ability to answer negatively as a fragment is the hallmark property of NPIs known as *n-words* (Laka 1990; Zannutini 1991, Giannakidou 2006). The emphatic NPI can be used as a negative fragment answer, but the non-emphatic NPI cannot. Giannakidou 1997, 1998, 2000 argues that the fragment NPI is the remnant of an elliptical structure, and “given that the remnants in fragment answers are accented, non-emphatics are excluded because they are not accented. Considering that utterances with non-emphatics typically involve pitch accent on negation, we may argue alternatively that ellipsis excludes non-emphatics because the accented negation itself must be deleted.” (Giannakidou 2000: 469). The negative fragment answer does not entail that the emphatic word is negative, since the structure contains ellipsis that itself contains negation.

(ii) *Licensing in islands*

Another difference between emphatic and non-emphatic NPIs with negation concerns locality. Non-emphatic NPIs, but not emphatic NPIs, are licensed in syntactic islands. The example below illustrates this with a relative clause (but other examples are given in Giannakidou 1998; see also Quer 1993 for a similar observation about Catalan *n-words*):

- (5) Dhen prodhosa mistiká [pu ekséthesan {kanénan/*KANÉNAN}]
betrayed.1st secrets that exposed.3pl n-person
I didn't reveal secrets that exposed anybody.

In this respect, non-emphatics are like *any*, which is also licensed in islands as we see in the translations. Importantly, the inability of KANENAN to be licensed in the island was one of the arguments in Giannakidou that set apart the emphatic NPI from a focus in situ which is typically fine in islands (see also Tsimpli 1995).

(iii) *Long distance licensing*

Given that non-emphatics appear in islands, it is not surprising that they also appear long-distance, again like *any*. Notice too the contrast with the emphatic NPI:

- (6) I Ariadne dhen ípe oti idhe {típota/*TÍPOTA}.
the Ariadne not said.3sg that saw.3sg n-thing
Ariadne didn't say that she saw anything.

The observed locality of the emphatic NPI is again typical of negative concord, and is reminiscent of universal quantifier dependencies, which are also clause-bounded (for Greek, see Farkas and Giannakidou 1996).

(iv) *Strict negative concord, and n-words as strong NPIs*

Greek exhibits *strict* negative concord, i.e. it always requires the presence of negation for the licensing of the emphatic NPI:

- | | | | |
|-----|---|--|-----------|
| (7) | a | KANÉNAS *(dhen) ípe TÍPOTA.
n-person not said.3sg n-thing
Nobody said anything.' | Greek |
| | b | Nikt *(nie) uderzył nigogo.
n-person not hit.3sg n-person
'Nobody hit anybody.' | Polish |
| | c | Balázs *(nem) beszélt senkivel semmiről.
Balázs not spoke.3sg n-person n-thing
'Balázs didn't talk about anything with anybody.' | Hungarian |

Greek, Hungarian, Japanese, Korean, and Slavic languages form a natural class in terms of strict negative concord, and require sentential negation even when more than one n-word occurs in a sentence. It is in this sense that n-words in these languages are strong NPIs: they need negation to be licensed (Giannakidou 1998, 2000), and cannot appear in non-negative nonveridical or downward entailing contexts:

- (8) Píjes {poté/*POTE} sto Parísi?
went.2sg ever in-the Paris
Have you ever been to Paris?
- (9) An dhis tin Eléna {puthená/*PUTHENA}, na tis milísis.
If you see Eléna anywhere, talk to her.
- (10) Pare {kanéna/*KANÉNA} mílo.
take.imp.2sg any apple
Take any apple.
- (11) Borí na írthe {kanénas/*KANÉNAS}
can.1sg subj left.3sg n- komati.
It is possible that anyone/someone came.

The nonemphatic NPI is further licensed in disjunctions, with various modalities, and habitual sentences. With a few exceptions (noted in the literature), these are also licensing contexts for *any*, but the Greek NPI lacks the free choice reading that any may exhibit in some of these contexts, and it is also non-scalar (Giannakidou 1997, 1998, **2009**). In all cases above, the non-emphatic NPI is a narrow scope, non-specific existential.

(v) *No double negation:*

The multiple emphatic NPIs in Greek do not give rise to double negation (Giannakidou 2000, 2006):

- (12) KANÉNAS dhen ípe TÍPOTA.
n-person not said n-thing
Nobody said anything.
It is not the case that nobody said anything.

The sentence does not have a double negative reading, as we would expect under the hypothesis that the n-words are negative (e.g. *Nobody said nothing*).

The strict concord property, locality, and the absence of double negation readings, along with a number of other diagnostics employed in earlier work, lead to the conclusion that Greek emphatics are not negative quantifiers, but rather, universal quantifiers interpreted outside the scope of negation (Giannakidou 1998, 2000). The difference between emphatic and non-emphatic NPIs, then reflects the following two logical structures:

- (13) *Logical representation of general negative statements*

- | | |
|--|--|
| a. $\forall x[P(x) \rightarrow \neg Q(x)]$ | (Universal negation, emphatic NPI) |
| b. $\neg\exists x[P(x) \wedge Q(x)]$ | (Existential negation, non-emphatic NPI) |

The two are of course truth conditionally equivalent, but Greek appears to reflect in the intonation the difference between a 'weak' (existential) dependency and a 'strong' (quantificational) dependency, as suggested by Ladusaw 1994. Space prevents us from going into more details (see the references

cited here for that). For the purposes of our experiments it suffices to note that the negative sentence with the emphatic maps onto the universal above negation structure.

Since Giannakidou's claim, universal NPI n-words have been identified in Korean (Yoon 2008), Japanese (Yoshimura 2007), and one variety of Hungarian n-words (Suranyi 2006). These n-words, crucially, also have emphatic intonation. Puskás 1998 in particular argues for Hungarian that "This stress [i.e., the accent observed in Hungarian n- words] cannot be assimilated with the stress assigned in FP [Focus Phrase] which has strong emphatic or identificational reading. Therefore it cannot be argued that Hungarian negative phrases carry the feature [+f]" (Puskás 1998, p. 199). Szabolcsi (1981, pp. 530–532) also observes that Hungarian n-words, on a par with universal quantifiers, "may not fill the F-position". If these n-words are also universal quantifiers, the fact that the accent is not focus ties in with their semantic function as universals, and supports the argument that the morphological feature of NPI-universal relies on intonational recycling.

(vi) *Negation, intonation, and scope in Greek*

Since we are talking about emphatic NPis scoping above negation, it is relevant to note the following generalization (Giannakidou 1998, pp. 71–73, 2000).

- (14) *The scope-negation generalization*
 In Greek, a pitch-accented quantifier takes wide scope over negation.

This is a general observation about quantifier and negation interaction. Giannakidou (2000: 480–481) offers the following examples:

- (15) I Ana dhen parakolúthise PARAPÁNO apó tría mathímata.
 the Anna not attended.3sg more from three classes
 Anna didn't attend more than three classes.

The English version of this sentence has two possible readings, depending on whether *more than three classes* scopes over negation or not. The first possibility is illustrated in the LF where *more than three classes* has adjoined to IP, and takes wide scope over negation. The second possibility indicates adjunction of *more than three classes* to VP, below negation.

- (16) a. [IP more than three classes₁ Anna didn't [VP attend t₁]]]
 b. [IP Anna didn't [VP more than three classes₁ [VP attend t₁]]]

Under the *a* reading, we know that there were more than three classes from which Anna was absent, and we have no idea how many classes she actually attended. In the *b* reading, on the other hand, with negation taking wide scope, Anna attended no more than three classes, and we don't know how many classes Anna was absent from. Hence, the two readings are true under distinct circumstances.

Now, the Greek sentence, with the accented QP, has only the wide scope QP reading, whereas accent on negation *dhen* permits only the wide scope negation reading. The use of 'accent' here is a bit impressionistic, but see Baltazani 2002 for a more phonologically informed description. So, accent seems to indicate the element taking wide scope.

Given what we have seen so far, we have two hypotheses that can be tested:

- (17) Hypothesis 1: The emphatic NPI hypothesis
 The sentence with emphatic NPI will *always* be interpreted as having the logical structure of a universal above negation. Emphasis is a morphological feature.
- (18) Hypothesis 2: The scope-negation hypothesis
 In Greek, a pitch-accented quantifier takes wide scope over negation and intonation serves to disambiguate.

In the rest of our paper, we describe the experiments we set up to test these hypotheses. Our findings show that the NPI-hypothesis is borne out, but the scope-negation hypothesis is a bit less robust. The difference suggests, as expected, that emphatic intonation functions differently in the two cases. In the NPI, it becomes conventional, it marks lexical association (morphological function), whereas in the quantifiers, emphasis functions as (a relatively systemic) intonational cue for scope disambiguation.

2. Prosody and Quantification

Sentences like (19) can be ambiguous in two ways depending on the scope relation between negation and the quantifier:

- (19) Every woman didn't sleep.
 a. "No woman slept" (every > not) = $\forall x [\text{woman}(x) \rightarrow \neg \text{sleep}(x)]$
 b. "Some woman slept" (not > every) = $\neg \forall x [\text{woman}(x) \rightarrow \text{sleep}(x)]$

The meaning in (a) is generated if *every* is interpreted as taking wide scope over negation whereas the meaning in (b) corresponds to the case where negation scopes over the quantifier. For English, it has been observed (Jackendoff, 1972; Steedman, 1991; Buring 1997) that each interpretation corresponds to a different prosodic structure; thus intonation was associated with the disambiguation of such sentences. In Greek, Baltazani (2002) investigated experimentally the interplay between prosody and quantification by adults conducting both a production and a perception study. In the perception part, the participants listened to sentences like (20) with a prosodic focus either on the negation or on the quantifier:

- (20) Δεν έλυσαν πολλά προβλήματα (= not solved many problems)
neg solved.3p many problems

The design included quantifiers like *πολλά* (=many), *λίγα* (=few) in object position within VO and OV orders. After listening to each sentence, the participants were given a table with 5 answers to choose which one corresponded better to the sentence they had just heard. In the case of (20), the 5 answers referred to *small* or *large* quantities of problems *solved* or *not solved*. The design was based on the hypothesis that sentence (20) under different interpretations refers to different quantity of solved or not solved problems. More specifically, the prediction was that, if negation is focused and takes wide scope, then (20) means «*the problems they solved are not many*», whereas, if the quantifier is focused and takes wide scope, then it means «*the problems they did not solve are not many*». The results showed that for both VO and OV orders, in the case of the upward entailing quantifiers, listeners associated wide scope with prosodic focus.

In the current study we explore how Greek-speaking children interpret emphatically realized NPIs and universal quantifiers in object position. Before describing the experiment we present previous experimental investigations on children's comprehension of sentences that contain negation and quantifiers and on children's ability of using prosodic cues in order to resolve different types of ambiguities.

2.1 Experimental investigations of existentially and universally quantified NPs

Musolino, Crain and Thornton (2000) tested children's comprehension of sentences that included negation and an existential or universal quantifier like (21) and (22):

- (21) Every horse didn't jump over the fence
 (22) The detective didn't find someone/some guys

As it was mentioned above, these sentences can be ambiguous between a wide scope and a narrow scope reading. The authors tested children (3 – 7 years old) in a series of experiments using a Truth Value Judgment Task (TVJT) during which participants see a scenario involving an agent acting as the main character who performs an action with different outcomes (he may fail or succeed) upon a set of objects or a set of other characters. Then they listen to a sentence, in the case of Musolino et al., a semantically ambiguous sentence containing a quantifier and negation like (21) and (22), that comments on the action performed in the scenario. At that point the participant is asked to respond by accepting or rejecting the comment. The benefit from such design is that the responses are associated with a different scope reading for the quantifier in the sentence-comment, which was exactly what Musolino et al. (2000) were investigating. Their results suggested that children showed a preference in resolving scope ambiguities on the basis of overt syntax whereas there was not such an observation for the adults. Musolino et al. coined the term *Isomorphism* for this phenomenon and the main claim made by the authors was that "children have INCOMPLETE rather than ACCURATE knowledge of the adult grammar" (Musolino et al. 2000, p. 2).

However, a different line of research of the same phenomenon suggests that inverse scope readings are in fact available in child grammar and that children differ from the adults in terms of their response strategy to infelicitous statements (Gualmini, 2004, p.8). In a TVJT, Gualmini showed that children accommodate differently sentences with the same truth-value but with different felicity properties with respect to a scenario they saw. Musolino and Lidz (2006) tested children at the age of 5 and reached a similar conclusion by manipulating the contextual conditions in a TVJT. According to the authors, this ability was “masked” in the design of Musolino et al. (2000) due to task-effects and what, in fact, children differ in is: “[...]their command of pragmatic principles associated with the use of quantified statements is much more fragile than that of the adults” (Musolino and Lidz, 2006, p.1).

In the developmental research on NPis, Thornton (1995) used a TVJT to investigate the comprehension of the English existential *any* in relation to the negation by children in the age between 3;6 - 4;11. The results showed that by that age children can generate both $\exists > \neg$ and $\neg > \exists$ readings depending on the surface position of the NPI with respect to the negation. Further evidence on the acquisition of the NPis comes from O’Leary and Crain (1994) who conducted an Elicited Production task (reported in Gualmini / Musolino et al., 2000.) in order to investigate children’s (4;4 -5;4) command of the NPI *any/anything* and the Positive Polarity Items (PPIs) *some/something*. The results showed that in the case of the NPI the children exhibited adult-like awareness of the distributional constraints that govern the licensing of *any*, whereas, according to the data, this conclusion did not apply on the case of *some*.

2.2 Experimental investigations of the use of intonation to resolve scope ambiguities

The experimental data from recent research on children’s ability to resolve ambiguities of different types do not point to a clear conclusion. Choi and Mazuka (2003) tested 3 and 4-years old Korean-speaking children in two tasks: one involved word segmentation ambiguities and the other structural ambiguity. The results showed that children effectively used the prosodic cue on word segmentation but not on the structural ambiguity task. Similar results are reported in Snedeker & Trueswell (2001) who investigated English-speaking, 5-years-old children’s competence with respect to the disambiguation of Prepositional Phrase (PP) attachment relying on prosodic cues. The results based on off-line judgments suggested that children failed to use prosodic information to disambiguate sentences like *tap the frog with the flower* in order to distinguish between a VP-attached instrument meaning or an NP-attached modifier meaning of *with the flower*. Zhou et al. (2011) report that 4 to 5-year-old Mandarin-speaking children did not use stress in order to resolve structural ambiguities that involved the focus particle *zhiyou* “only” whereas adults did. While this result was based on off-line judgment data, Zhou et al. also used an on-line technique (eye tracking), the results of which brought evidence that children did indeed use stress.

Against this skepticism, it seems that there is experimental evidence supporting the view that children use prosodic information effectively in order to resolve different types of ambiguities. Zhou et al.’s in the same paper describe a second experiment where the data showed that children prosodic cues in order to resolve a *speech act* ambiguity in the case *wh*-phrases in Mandarin. Nakassis & Snedeker (2002) explored the degree to which children use prosodic information in the comprehension of ironic statements. Their findings suggested that during comprehension of ironic statements children were as sensitive as the adults to particular prosodic realizations of such statements when uttered within specific type of contexts that triggered non-literal interpretations. Finally, Snedeker & Yuan (2008) in a follow up of Snedeker & Trueswell (2001) investigated the relation between intonation and PP-attachment, this time using an on-line eye-recording method and found evidence that children used the prosodic cues to resolve the structural ambiguity.

3. THE PRESENT EXPERIMENT

In light of the above considerations the primary research question we addressed was the extent to which children associate prosodic focus on a universal quantifier or an emphatic NPI with wide scope reading. This gives the opportunity to investigate how children use prosodic cues in the interpretation of universally quantified structures in Greek and whether the wide scope reading can be attributed to a general effect of the prosodic component or alternatively whether it is a morphological feature of specific lexical items.

The experiment was designed to test children’s comprehension of sentences where an emphatically realized NPI or universal quantifier occurs in a post-negation position in the overt syntax. The

questions that arise are whether children interpret the quantified expressions as taking wide scope over negation and whether this is a general mechanism that applies both in the case of the NPIs and the universal quantifiers. For this reason we compared the emphatic NPI “KANĒNA” with the quantifier “όλα” (=all) located in a post-negation object position.

This study might also add to the discussion about children’s competence in using prosodic cues in order to resolve different types of ambiguities and their ability to access both isomorphic and non-isomorphic interpretations.

3.1 Participants

We tested 18 Greek-speaking children (8 boys and 10 girls) aged from 5;8 to 6;2 (mean 6) years. The children were selected from a primary school in Greece. After the studies of Thornton (1996) on NPIs and O’Leary & Crain (1994) on NPIs and PPIs, both in English, we know that children younger than 6 are competent in the production and comprehension of these lexical categories. However, our reason for testing subjects of age 6 was that the experimental task we engaged the subjects in involved competence in the use of prosodic information. That was an extra task compared to the previous studies in English. Moreover, taking into consideration the mixed results on children’s ability to use prosodic information for resolving semantic/pragmatic ambiguities, we decided to test subjects 1-2 years older than those that Thornton and O’Leary & Crain tested.

3.2 Procedure

We tested the subjects using a TVJT (Crain and Thornton, 1998; Musolino et al. 2000) during which the participants saw a pictorial scenario on a computer screen where an agent was performing an action upon a set of objects (4 or 5 objects) and listened to a sentence that contained an NPI or a universal quantifier. The sentence was a statement relevant to the outcome of the agent’s action and the participants were asked to accept or reject the statement. A third option of “not sure” was also available.

3.3 Materials

The pictorial scenario consisted of cartoon pictures and the sentences - statements were pre-recorded in order to control for uniformity regarding the prosodic realization of the utterances, since this was important for the study. The stories depicted a set of four or five objects (apples, windows, etc.) and an agent who was supposed to perform an action related to the objects. Each pictorial scenario was preceded by an introductory written text that introduced the subjects to the main character and the set of objects that appeared on the screen. It was 1 – 1,5 lines long and it was designed to be as neutral as possible by providing only the necessary context for the interpretation of the scenario. Fig. (1) shows an example of a pictorial scenario:

[introductory text]

*Mary is a cleaning lady. In the morning she opens the windows of the house she is cleaning.
This morning:*

Figure 1

Since this study addresses the question of whether the prosodic focus on universal quantifiers triggers a wide scope interpretation, we used sentences - statements like those in (23) - (25) that differed only in the use of an emphatic NPI or a universal quantifier in an object position.

(23) Δεν άνοιξε ΚΑΝΈΝΑ παράθυρο
neg opened.3s n-thing window
“She didn’t open any window”

(24) Δεν άνοιξε ΌΛΑ τα παράθυρα
neg opened.3s ALL the windows
“She didn’t open all the windows”

(25) ΔΕΝ άνοιξε όλα τα παράθυρα
neg opened.3s all the windows
“She didn’t open all the windows”

The crucial conditions were sentences (23) and (24) that contain an emphatic NPI and an emphatically realized universal quantifier respectively. In each of these sentences, the highest peak of the sentence is aligned with the quantificational expressions. If the prosodic focus is in general associated with wide scope then we should expect that both ΚΑΝΈΝΑ and ΌΛΑ would be assigned a wide scope interpretation. The expectation about the quantifier in (25), which is not in prosodic focus, is to be interpreted under a narrow scope reading that corresponds to the overt syntax of the sentence (Musolino et al., 2000).

The motivation for using the quantificational expressions only in a post-negation position was to minimize the effect of *Isomorphism* that Musolino et al. (2000) observed under a similar design. If ΚΑΝΈΝΑ or ΌΛΑ were preceding the negative marker, the wide scope reading associated with these elements could be attributed to some extent to the surface syntactic position of these elements. By putting ΚΑΝΈΝΑ and ΌΛΑ in a post-negation position, we minimize the association between overt syntax and wide scope. Thus, limiting the effect of overt syntax, we can be more confident that the wide scope interpretation of ΚΑΝΈΝΑ or ΌΛΑ emerges through a covert movement in the LF triggered by the prosodic focus. In this case, the NPI or the universal quantifier moves covertly to a position above the negation and this movement generates the wide scope reading.

We manipulated the cartoon pictures in order to design scenarios where the sentence - statement was true under a narrow scope reading and false under a wide scope reading. We also added scenarios where the sentence was true under the wide scope and false under the narrow scope reading. The task lasted approximately 20-25 minutes and participants were presented with 30 experimental items and 15 fillers in each condition. Each participant received 6 practice trials before the main session.

3.4 Results

Table 1 presents the frequencies for wide, narrow scope answers as well as for “I am not sure” responses.

<i>NPIS</i>	<i>WIDE SCOPE</i>	<i>NARROW SCOPE</i>	<i>NOT SURE</i>	<i>TOTAL</i>
<i>KANENAS</i>	149	1	30	180
<i>OLA</i>	77	36	67	180
<i>óla</i>	10	139	31	180

Table 1 Scope interpretation for NPIs

The results indicate that the children confidently associated prosodic focus with wide scope in the case of ΚΑΝΈΝΑΣ, whereas the wide scope answers were fewer for the case for ΌΛΑ. As expected, children consistently associated the neutrally realized *óla* with narrow scope under negation. The following figure illustrates this set of data in percentages.

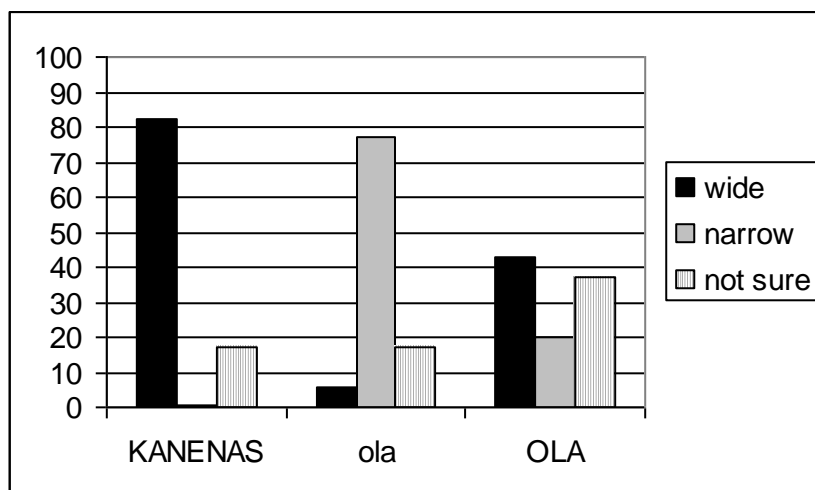

Figure 2 Scope interpretations for NPIs (%)

In order to detect whether the type of the quantifier affected the children's responses we conducted non-parametric correlation analyses, excluding all "not sure" answers. The first analysis in which we compared the responses for *KANENAS* with those for *OLA* showed that the quantifier correlated with the participants' performance ($\chi^2=51.867$, $p=.000$, Cramer's $V=.444$), in that there were significantly more wide responses for *KANENAS* than for *OLA*. Furthermore, there was a significant correlation between quantifier type and scope interpretation when the data from *OLA* and *óla* conditions were analyzed ($\chi^2=109.338$, $p=.000$, Cramer's $V=.646$). This means that *OLA* yielded significantly more wide scope responses than *óla*. Moreover, chi-square tests performed on the data from each quantifier revealed that the wide scope readings significantly outnumbered the narrow responses for both *KANENAS* ($\chi^2=146.027$, $p=.000$) and *OLA* ($\chi^2=14.876$, $p=.000$), whereas the opposite pattern was attested in the case of *óla* ($\chi^2=111.685$, $p=.000$).

4. Conclusion

The results show that intonation did not have the same effect on an emphatic NPI and a pitch accented universal quantifier in Greek. Children showed a strong preference in associating *KANÉNA* with wide scope above negation, therefore we conclude that the emphatic NPI hypothesis is confirmed. Since intonation was not found to have a similar function in the case of *ÓΛΑ*, we assume that emphasis is not associated with wide scope over negation in general. These observations suggest that the association of emphatic intonation with wide scope is a function specific to the emphatic NPIs in Greek as part of the lexical entry. Furthermore, the subjects were sensitive to the prosodic cues conveyed by the NPI and could effectively map intonation to semantics. Interestingly, children appeared to be in position to judge when prosodic emphasis was linked to wide scope and when it was not, which perhaps shows a certain degree of competence in mapping intonation to semantics. This might be considered as evidence to the direction that children are competent users of the prosodic information when it comes to the semantic interpretation.

Concluding, the results showed that the children in the age of 6 systematically interpreted the emphatic NPI *KANÉNA* as a universal quantifier above negation. It can be argued that in the case of the emphatic NPI the association between emphasis and wide scope becomes conventional whereas for the universal quantifier *ÓΛΑ* emphatic intonation was not found to have a similar function.

BASIC ILLOCUTIONS OF THE MODERN GREEK INDICATIVE

Maria Chondrogianni

University of Westminster

M.N.Chondrogianni@westminster.ac.uk

ABSTRACT

In this paper we propose a pragmatic analysis of the Modern Greek Indicative, following a systematic hierarchical classification of propositional and behavioural basic illocutions (Hengeveld et al. 2007). Morphosyntax, Pragmatics and Phonology allow us to establish each basic illocution in terms of its prosodic contour; the use of segmental markers; grammatical tense restrictions, including number and person restrictions; aspectual restrictions; and the potential answer provided by an addressee to a question, or to a question-like utterance. To that end, we outline prosodic contours in 5 defined intonation patterns and we demonstrate how they apply to Indicative's uses with distinct encoding.

Keywords: Pragmatics, Phonology, intonation patterns, indicative, basic illocutions, grammar

1. Introduction

The aim of this paper is to describe the basic illocutions of Modern Greek (MG) Indicative, which from part of the MG grammatical system. As basic illocutions are expressed by the speaker in various forms, using syntactic, morphological and phonological means, the interface between Pragmatics, Phonology and Morphosyntax is crucial for this work.

Our view is inspired by the framework of Functional Discourse Grammar (FDG, Hengeveld and Mackenzie 2008), a typology based structural functional discourse grammar. Its grammatical component consists of the interpersonal level (Pragmatics), the Representational level (Semantics), the Morphosyntactic level (Morphosyntax) and the Phonological level (Phonology).

According to Hengeveld (2004) 'mood is used in language description as the morphological category that covers the grammatical reflections of a large semantic area, subdivided into illocution and modality' (Hengeveld 2004:1190). Illocution involves identifying sentences as "specific types of speech acts" (ibid) whilst modality "is concerned with the modification of the content of speech acts" (ibid). As this research is not concerned with the modification of the content of the speech acts, semantics (modality) does not form part of it. It is useful to also note that, as far as illocution is concerned, the verb mood, as a morphological category (always according to Hengeveld 2004), "has to be considered together with word order and intonation, as markers of particular sub-divisions". By contrast, "modality is expressed by modal markers only". The formal properties which are considered having an illocutionary impact might also include specific mood markers. Illocutionary differentiation applies to main clauses only, while modality is expressed in both main and subordinate clauses.

Thus, the aim of our research is to provide a systematic *description* of the basic illocutions (with Modern Greek as the natural language of application), as expressed in main clauses, based on their formal characteristics i.e. based on distinct markers that have an illocutionary impact. Markers we consider include the verb mood; the indicative associated negation $\delta\epsilon(v)$; the prosodic contour utterances are expressed in (i.e. the intonation patterns at the level of utterance); number, person and tense where applicable; the addressee's response, where applicable; and any additional segmental markers that apply.

Our primary objective is to identify the relationship between form (i.e. verb mood, prosodic contour) and function (basic illocution); in other words, to present the basic illocutions which form part of a grammatical system and to provide a comprehensive classification of their uses. Moreover, we wanted to apply in MG the basic illocution hierarchy as proposed by Hengeveld et al. (2007).

The term *grammatical mood* is used in this work as the category which includes "all grammatical elements operating on a situation/proposition, that are not directly concerned with situating an event in the actual world, as conceived by the speaker" (Hengeveld 2004). Noonan (1985) defines Indicative as the form that 'mostly resembles declarative main clauses', while Hengeveld (2004) stresses that "they are not one and the same". It is debatable whether one can argue that declarative uses are the typical

uses of the Indicative, since, for example, the Indicative is used just as much in questions, suggesting an Interrogative as well as a Declarative value.

Hengeveld et al. (2007) distinguish basic illocutions into propositional and behavioural uses. Propositional uses are associated with assertive and questioning illocutions; assertive subtypes consist of declarative and mirative uses, whilst questioning subtypes consist of polar and content interrogatives. Behavioural uses involve speech acts that intend to influence or affect the behaviour of the Addressee and/or others. Behavioural (positive and negative) uses include imperative subtypes (orders), hortative subtypes (exhortations), admonitive subtypes (warnings) and supplicative subtypes (requests for permission).

Below we will describe the methodological considerations that underpin this research; the intonation patterns we established and used as a tool to identify the prosodic contour at utterance level; and the characteristics of the MG indicative and its propositional and behavioural basic illocutions.

1.1 Methodological considerations

As part of the first phase of this work, which involved the identification of morphosyntactic tools speakers have at their disposal to express their intention, the MG Indicative mood was established through a series of tests involving morphology; use of particles; negation; clitic placement; and participation to subordination. Following this, the phonological tools speakers have at their disposal to express their intentions were identified: a hypothesis on 5 intonation patterns used was established, which was recursively confirmed using of Praat. Data were collected introspectively; they were, however, verified by an informal group of informers and by mini internet searches. This was followed by a production experiment in studio conditions, which allowed to establish the intonation patterns, as described in section 2 below, which contributed to the identification and analysis of the indicative's propositional and behavioural basic illocutions. The results were classified based on their function and characteristics.

2. Intonation patterns in MG (utterance level)

Levinson (2003) highlights the need for a systematic study of prosody, intonation and stress and emphasises the importance of prosodic features in the study of Pragmatics, an area "hugely understudied".

We considered Arvaniti and Baltazani (2005), as well as their GRTToBI relevant website, who, in describing GRTToBI's Tone Tier state, define three types of tonal events: the *pitch accent*, the *phrase accent*, and the *boundary tones*. In addition, they identify two levels of phrasing: the *intermediate phrase* and the *intonational phrase*. The pitch accent effectively coincides with the stressed syllable of a word in MG (bearing in mind that syllables might be stressed but not accented, stressed and accented or unstressed, as well as that a word might potentially carry two pitch accents). An utterance's intonation pattern is also influenced by a speaker's topicality and focality choices. Such choices, however, when they are made at the discretion of a speaker, for example affected by their psychology, (and, therefore, are not imposed by grammar) cannot be considered as part of the grammatical component; they belong to the Output Level as defined by Functional Discourse Grammar (Hengeveld and Mackenzie 2008).

Our approach is focused on five generic, schematic intonation patterns as one of the criteria for identifying specific illocutions. Intonation Patterns 1, 2, 3 and 4, presented below, are relevant to indicative, while intonation pattern 5 is applicable to subjunctive (curses).

2.1 Intonation Pattern 1 (INT1)

The characteristic of this pattern is its broad focus and a high level of the accented syllable. Its The Fundamental Frequency (FO) characteristics include a heightening of the pitch (starting at the first accented syllable) with a pick at the first post-accented syllable, followed by a small dip and a fall. Its boundary (i.e. the final phrase on the utterance) is low. The nucleus might create variations on this pattern. Moreover, in some cases it can be used interchangeably with INT2 below, when the speaker's focality choices affect the way an utterance is expressed. Figures 1 and 2 below illustrate this pattern.

Figure 1 Schematic representation of INT1

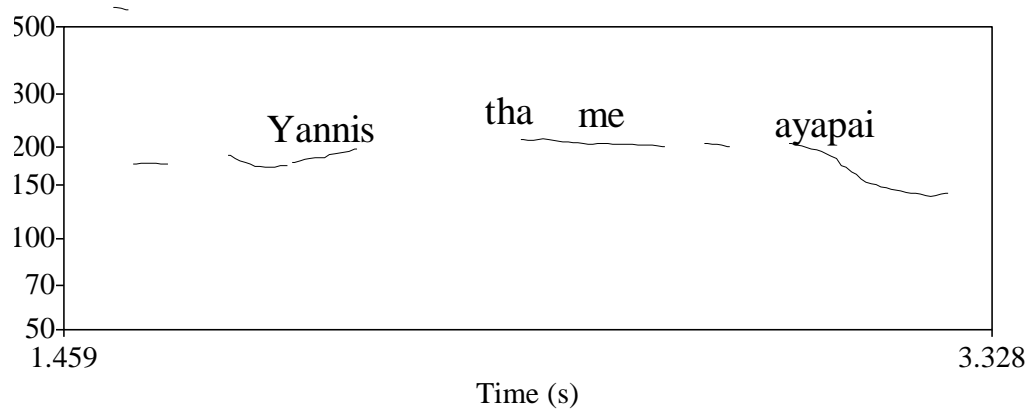

Figure 2 Praat illustration of INT1

2.2 Intonation Pattern 2 (INT2)

Intonation pattern 2 (INT2) is characterised by narrow focus and a rise from low to the accented syllable. Usually it starts with a plateau followed by a rise on the nuclear, and then a fall from the post nuclear syllable onwards. Its boundary is also low. Figures 3 and 4 below illustrate this pattern.

Figure 3 Schematic representation of INT2

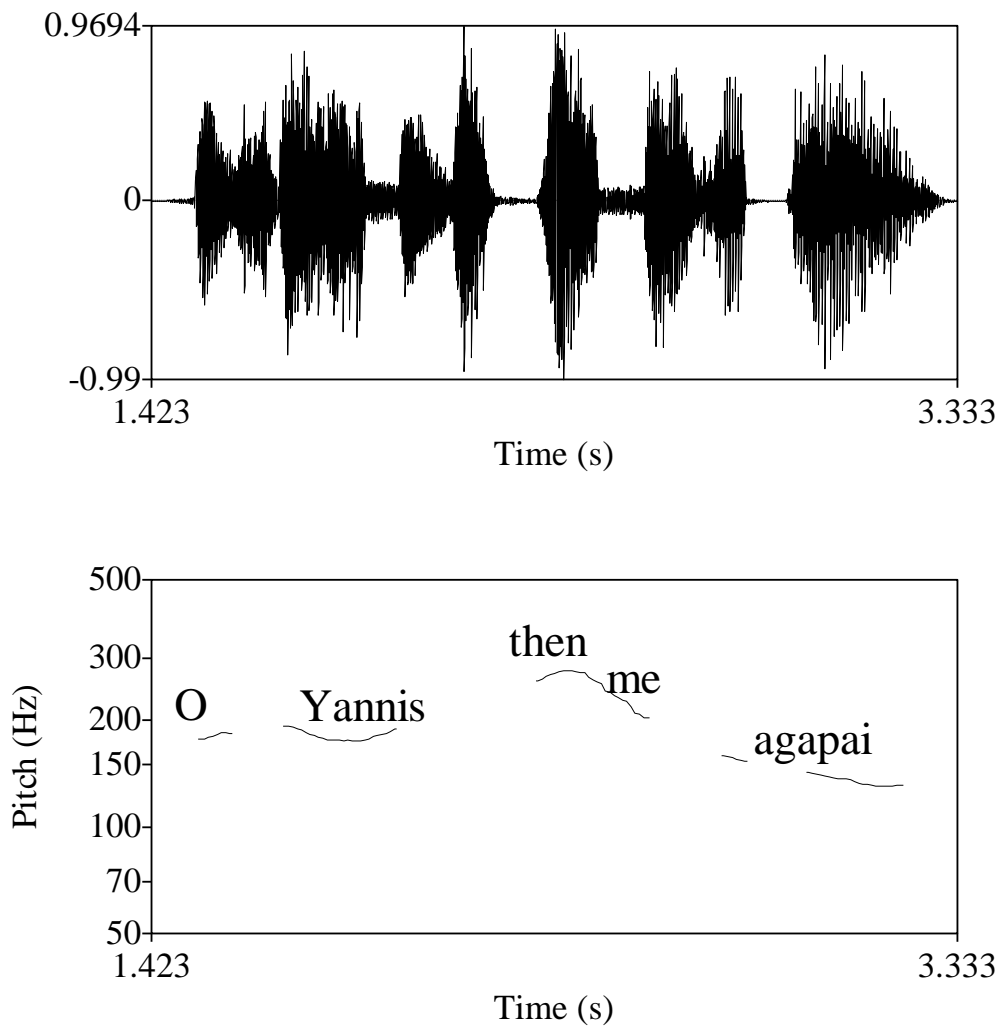

Figure 4 Praat illustration of INT2

2.3 Intonation Pattern 3 (INT3)

This is the typical pattern for content interrogatives (although it use extends to other basic illocutions). It starts high with the first accented syllable, and it starts dropping immediately after, with a potential rise at the end. The boundary is high. Questions are typically expected to finish with a rising intonation. However, the question word itself provides a key to the addressee on how the utterance is to be interpreted, hence a variation with a slightly rising, level, or slightly falling intonation is not unexpected. Figures 5 and 6 below illustrate this pattern.

Figure 5 Schematic representation of INT3

Figure 6 Praat illustration of INT3

2.4 Intonation Pattern 4 (INT4)

This is the typical (but not exclusive) pattern for Polar Interrogatives. The pick is on the last stressed syllable of the final word. Following a gradual fall, we have a low plateau followed by a rise. The boundary is high-low. Figures 7 and 8 illustrate this pattern.

Figure 7 Schematic representation of INT4

Figure 8 Praat illustration of INT4

3. The Modern Greek Indicative

Indicative in MG is identified by morphology, as a non-imperative form which lacks a typical particle (we note the optional use of the future particle $\theta\alpha$). All indicative negative uses are introduced by the negation $\delta\epsilon\nu$. Although indicative is considered aspect-neutral (Holton et al. 1987), we accept non-independent forms introduced by the negation $\delta\epsilon\nu$ as forming part of the indicative.

Indicative mood is often associated with the Declarative sentence type; however, they are not one and the same. Although Declaratives can only be expressed in indicative, the indicative is deployed for a variety of propositional and behavioural uses. The Declarative sentence type in the indicative is mostly associated with propositional uses.

Below we present propositional and behavioural uses in indicative, as well as uses related to additional segmental marking.

3.1 Assertive uses of the Indicative

The default interpretation of a declarative sentence type across languages is an assertion (Hengeveld et al. 2007). This type of propositional basic illocution, which seems to be universal, aims to provide the addressee with intonation. It is marked by the use of indicative and the intonation INT1 (as defined in

section 2.1 above), in interchangeable use with INT2 (when the speaker opts to focus on a particular element of the utterance. No tense, aspect, person, or number restrictions apply. Example (1) shows an example of an assertion.

- (1) Ο Γιάννης με αγαπάει.

The Yannis me love-3S.PR.IPF.

Yannis loves me.

Negative assertions do not form part of a separate illocution. They are commonly expressed in INT2, with focus been placed on the negation.

- (2) Ο Γιάννης δεν με αγαπάει.

The Yannis NEG me love-3SG.PR.

Yannis does not love me.

Assertions might be emphasised; we then notice a complex interaction between the overall prosodic contour and the emphasis (focus) a speaker might place to a specific constituent in an assertion. There is a lack of specific grammatical strategy in such cases; speakers might emphasize an assertion through lexical means (e.g. using words such as *οπωσδήποτε* ‘definitely’) or through narrow focus on specific clause constituents. Such focal points might be verbal as in (3), nominal, or adverbial.

- (3) **Θα πας** στο γιατρό αύριο.

FUT go-2SG.PRF to-the doctor tomorrow.

You will go to the doctor tomorrow.

Speakers might also express assertions disguised as questions. In these disguised uses of the indicative a question-like intonation is used to achieve a special effect. The fundamental difference between rhetorical questions and interrogatives is that speaker here does not intend to elicit information. Both the speaker and the addressee are aware that no particular response is expected. Often formulaic in nature, assertions in disguise are commonly used to criticise the addressee’s behaviour. (rhetorical questions and contrastive statements). Examples (4) illustrates the potential formulaic nature of an assertion in disguise, while in (5) the speaker criticises the addressee for non-complying with their request. Assertions in disguise are usually expressed in past or future in INT4.

- (4) Πόσες φορές θα σου πω...;

Poses fores tha sou po...

How many times FUT you tell-1SG.PRF

How many times will I tell you...

- (5) Πόσες φορές θα σου πω να κάνεις ησυχία;

Poses fores tha sou po na kanis isihia?

How many times FUT you tell-1SG.PRF SUBJ do-3SG quietness?

How many times will I have to ask you to be quiet?

Assertions might also be disguised as contrastive statements, marked by the use of a tag question, an additional strategy speakers have at their disposal in order to best achieve their intention. The unique character of this basic illocution is based on the use of the 1st person, as well as the fact that the tag-question is used as a compulsory element of the utterance’s structure, as in example(6). INT2 applies to the matrix, and INT4 applies to the tag. Such utterances reflect the speaker’s reaction to something the addressee has said or done. Despite the question-like intonation of the tag, the speaker does not need a positive or negative response from the addressee. If expressed in the 2nd or 3rd person, such utterances express the speaker’s request for the addressee to confirm the propositional content of the matrix (requests for confirmation), as in example (7), where the Speaker expresses an assertion in indicative, and adds the tag *έτσι δεν είναι* (isn’t it). It is interesting to note that in Modern Greek this formulaic tag might be used irrespective of the particular verb used in the matrix, unlike English, for example, where the verb in the tag matches the verb in the matrix. The negative *δεν* (‘den’) is used here for emphasis, rather than as a negation of the matrix. The tag might take various forms.

- (6) Στο έχω πει να πλένεις τα χέρια σου, δεν στο έχω πει;

It have-1SG.PR told SUBJ wash-2S.PR.IPF the hands your, NEG it have told?

I have already told you to wash you hands, haven’t I?

- (7) Θα έρθεις αύριο, έτσι δεν είναι;

FUT come-2SG.PF tomorrow, like that NEG is?

You will come tomorrow, isn’t it (won’t you)?

3.2 Mirative uses of the indicative

When speakers utter an assertion, they intend to share some information with their addressee. When they express admiration, surprise or delight through an utterance, effectively they also share some

information with their addressee. In this type, it is not so much the content of the utterance itself that is being transmitted, but rather the emotional reaction of the speaker with respect to this content. (Hengeveld et al. 2007).

Utterances in this category demonstrate a mixture of declarative properties (sharing of information, i.e. positive reaction) and interrogative properties (content interrogative intonation characteristics). However by contrast to content interrogatives, the speaker does not question a particular part of the utterance and does not expect a response by the addressee which clarifies a particular question-word (apart from a potential reaction of gratitude). An example of a mirative we see in (8).

- (8) Τι ωραίο φόρεμα είναι αυτό!
What beautiful dress be-3SG this!
What a beautiful dress is this!

3.3 Interrogative uses

According to Givon (1989), the goal of a Declarative sentence type utterance is to impart information, whilst the goal of an Interrogative sentence type is to elicit information, either ‘to confirm the identity of an item’ (for WH-questions, or content interrogatives), or ‘to confirm the truth of a proposition’ (for Y/N questions, or polar interrogatives).

Questions in Modern Greek indicative include polar and content interrogatives. Polar interrogatives are differentiated from assertions only by their intonation pattern. According to Mennen and Okalidou (2007), their intonation pattern is ‘low level from the accented syllable; it appears as the nuclear accent before a continuation rise’. In chapter 3 we defined this intonation pattern as INT4.

Content interrogatives are marked by question words such as *ποιός*, (‘pios’, who), *πού* (‘pou’, where), *τι* (‘ti’, what), *γιατί* (‘yiati’, why), *πώς* (‘pos’, how), *πότε* (‘pote’, when) which identify the piece of information the Speaker is missing; it is also possible to question more than one element in a clause. Moreover, MG content interrogatives are marked by intonation, reflecting our intonation pattern INT3. Mackenzie (2009) has published an extensive research on content interrogatives based on a sample of 50 languages.

In this section we compare Interrogative sentence types with Declarative ones to the extent that they use the Indicative.

3.3.1 Polar interrogatives

Polar questions in MG are differentiated from declarative uses by their distinct intonation. The clausal word order is determined by topicality/focality relations. A ‘yes’ (ναι), ‘no’ (όχι), maybe (ίσως) or ‘possibly’ (πιθανόν) answer is expected from the addressee. We believe that answers denoting consent, such as *εντάξει* (OK) refer to behavioural uses, rather than to the confirmation of the propositional content of the utterance, and would be unacceptable to a polar interrogative such as (9). Polar interrogatives are marked by intonation INT4. No other tense, aspect, person, or number restrictions apply. An example of a polar interrogative can be seen in (9). The Praat illustration of this example can be seen in figure 8, section 2.4 above.

- (9) Μιλάς αγγλικά;
Speak-2SG.PR. English?
Do you speak English?

3.3.2 Content interrogatives

Content interrogatives involve the use of question words. The speaker intends to elicit information specifically related to the slot in the sentence currently filled by the question word, questioning the agent, the goal, the time, or the manner, among others. Content interrogatives are marked by the use of a question word, in combination with intonation INT3. No other features’ restrictions apply. In example (10) the speaker seeks additional information regarding the time of the action described. A Praat illustration of this example can be seen in figure 6, section 2.3 above.

- (10) Πότε μπορείς να με πάρεις τηλέφωνο;
When can-2S.PR.IPF.PRT me call-2S.PR.PF phone?
When can you call me on the phone?

3.4 Other propositional uses of the indicative

The secondary basic illocutions described below involve the use of segmental markers, i.e. additional means which offer clues to an addressee on how a particular utterance is to be interpreted. We identify the segmental markers *άραγε*, marking a wondering use, and *ίσως*, denoting uncertainty.

3.4.1 Wondering in indicative

This category involves question-like utterances where the speaker does not necessarily expect an answer from an addressee. Wondering in indicative is marked by the segmental marker *άραγε* (which can also precede a subjunctive, in a fixed position in 1st or 3rd person only) combined with intonation INT4. In indicative its sentence position is not fixed. An example of its use we see in (11).

- (11) *Άραγε βρέχει;*
WND rain-3SG
I wonder, is it raining?

3.4.2 Uncertainty in indicative

Another segmental marker available to the MG speaker when they want to express uncertainty towards the propositional content of a clause involves the use of the particle *ίσως* combined with intonation INT2, with the segmental marker acting as the focal point of the utterance. In indicative it can precede or follow the verb, and can combine with the past, the present (in both its independent and dependent from) and the future (particle *θα*). Its combination with the negation *δε(v)* indicates that even the dependent use falls within the scope of indicative. *Ίσως* can also combine with subjunctive (for a reinforced expression of uncertainty); in that case, though, its position is fixed at the beginning of the sentence. In (12) we can see an example of its use (negative past).

- (12) *Ίσως δεν έφυγε.*
UNC NEG leave-3SG. PS.PRF
Perhaps he left.

3.5 Behavioural uses of the Indicative

The utterances shown below involve uses where the addressee, through a question-like utterance, intends to affect the addressee's behaviour. Behavioural uses of Indicative further strengthen the argument that there is no one-to-one relationship between Indicative Mood and Declarative sentence type. We describe two such distinct uses, namely exhortations in indicative and proffer.

3.5.1 Exhortations in indicative

Examples (13) and (14) below might look like content interrogatives. We ought to take into account, though, that the speaker effectively asks the addressee to change their behaviour, rather than intending to acquire a confirmation of the truth value of the utterance. The speaker expresses effectively an exhortation, the fulfillability of which depends on both the speaker and the addressee. Such utterances occur in the first person plural only. These, in our view, are distinct behavioural uses of polar interrogatives because the speaker is seeking consent for joint action from the addressee. Their intonation INT4 is consistent with other polar interrogative-like uses.

The interpretation of the indicative use in examples (13) and (14) below can be seen as rather controversial, in that the only feature that differentiates it from a polar interrogative is the potential consent response, such as *εντάξει* ('entaksi', OK) that the addressee might provide to the speaker's request, which would not usually follow a non-behavioural use.

- (13) A: *Φεύγουμε;*
Leave-1PL.PR.IPF
Let's go.
B: *Εντάξει.*

- OK
 (14) Πάμε πλατεία;
 Go-PL.PR square?
 Shall we go to the square?

The first person plural use is consistent with expressions of exhortation, (for example uses introduced by *ας* combined with intonation INT1). The verb might be in the past or in the present tense.

3.4.1 Proffer and the use of μήπως

The particle *μήπως* has a series of uses in MG. It can act as a mitigator of the illocutionary force or as a discourse marker (see also Chondrogianni 2011). *Μήπως* is considered by some scholars a subjunctive marker, while others are stating that it can be used as both a subjunctive and an indicative marker (e.g. Babinotis and Clairis 1999). We note, however, that it cannot combine with the subjunctive - associated negation *μη(ν)*, nor with the subjunctive particle *να*. It is negated with the indicative- associated negation *δε(ν)* and can combine with the future particle *θα*. We suggest, therefore, that *μήπως* can only be considered an indicative marker.

In example (15) below, introduced by *μήπως*, the speaker offers the addressee their help in a non-offensive way; they are attempting a change of heart from the addressee, i.e. to get them to accept the help on offer (as there is nothing wrong in doing so), by mitigating the strength of the proposition in the question. This question-like utterance, always in the second person, offers the speaker the opportunity to provide a form of advice, expressed as a mitigated question, in order to change the addressee's behaviour and get their consent for an altered behaviour. The utterance is expressed in intonation INT4.

- (15) Μήπως θέλετε βοήθεια;
 PROF need-2PL.IPF help?
 Perhaps you want some help?

4. Conclusion

In this paper we described the propositional and behavioural uses of the MG indicative. All indicative uses are marked by the optional particle *θα* and the optional negation *δε(ν)*. Propositional uses include: assertions, distinguished by the use of indicative and the use of intonation patterns INT1 or INT2; and assertions in disguise- contrastive statements which include either a compulsory tag (when their intonation involves intonation patterns INT2 for the assertive part and INT4 for the tag). When in the second or third person (excluding *μήπως* uses), the use expresses a request for confirmation.

In addition, propositional uses include miratives of approval, distinguished by the use of the indicative, the use of intonation pattern INT3 and, when compared to content interrogatives, the lack of question word related response from the addressee. Propositional uses also include content interrogatives, distinguished by the use of the indicative, the presence of a question word (such as who, what, when where, how equivalents), the use of intonation pattern INT3 and the expectation that the addressee's response will provide information on the questioned element of the utterance; and polar interrogatives, which are distinguished by the use of Indicative mood, the intonation pattern INT4, and the expectation that a positive or negative response (or a response expressing a degree of certainty or uncertainty) will be provided by the addressee. Secondary basic illocutions include wondering uses, distinguished by the use of Indicative, the segmental marker *άραγε*, and the most common use of 3rd person (also the use of 1st person in deliberative questions).

Behavioural uses include proffer (mitigated questions), expressed in Indicative, introduced by the segmental marker *μήπως*, expressed in INT4, in the 2nd person.

There are two uses in Indicative that are differentiated from the Polar Interrogatives use because of the Addressee's response, namely the Exhortations in Indicative (behavioural use), expressed in the first person plural only, where a response of consent (or lack of) is expected; and the assertions in disguise/rhetorical questions (propositional use), where no response is expected by the addressee.

Table 1 below summarises the basic illocutions in indicative which form part of the grammatical system.

We hope that this work will further support a different approach in the way grammar is taught in a first or second language acquisition setting, extending the focus from morphosyntax to also include pragmatics and phonology.

Uses	Verb Mood	Intonation Pattern	Segmental Marker	Possible Answer	Person	Aspect
Assertions	Ind	INT1/INT2	-	N/A	Any	Any
Mirative Uses –Approval	Ind	INT3	(exclamative)	N/A	Any	Any
Interrogative uses: Content Interrogatives	Ind	INT3	Question word	Element Questioned	Any	Any
Assertions in disguise-rhetorical questions	Ind	INT3 or INT4	-	None expected	Any	Any
Interrogative uses: Polar Interrogatives	Ind	INT4	-	Yes/ No	Any	Any
Exhortations	Ind	INT4	-	Consent	1 st	Perf for Past
Mitigated questions/ Proffer	Ind	INT4	μήπως	Consent	2 nd	Imp
Wondering	Ind	INT4	άραγε	N/A	3 rd (1 st for deliberative)	Any
Assertions in disguise-contrastive statements	Ind	INT2 + INT4 (with tag) INT4 (with μήπως)	Tag question	N/A	1 ^s	Any
Requests for confirmation	Ind	INT2+ INT4	Tag question	Yes/ No	2/3	Any
Uncertainty	Ind	INT1	ίσως	N/A	Any	Any

INCORPORATING CORPUS DATA AND SEMANTIC THEORY IN MODERN GREEK LEXICOGRAPHY: A SPECIAL REFERENCE TO THE SELF-MOTION USES OF *ΠΕΤΑΩ*

Thomai Dalpanagioti
University of Athens, Greece
tdalpag@enl.uoa.gr

ABSTRACT

This paper aims to make a contribution towards improving Modern Greek lexicography by drawing attention to the need for empirically-grounded, theoretically-informed and user-friendly entries. Focusing on the network of the self-motion (as opposed to the cause-motion) uses of πετάω (= fly), I first take a look at two dictionary entries pointing out their differences in content and form. To create an accurate semantic picture of the verb, I propose establishing lexical units (LUs) on the basis of a corpus-based, frame-driven, and cognitive-oriented methodology. Therefore, I present a new skeletal structure for the πετάω entry, and offer suggestions for making long entries more user-friendly.

Keywords: word sense disambiguation, lexical unit, corpora, FrameNet, metaphor, metonymy

1. Introduction

The study is motivated by the observation that the treatment of πετάω –a polysemous manner-of-motion verb of high frequency– differs considerably between the two main comprehensive dictionaries of Modern Greek, i.e. *AKN* (1998) and *ANEF* (2005). To clarify the picture, I examine the relevant data available in two electronic corpora of Modern Greek, i.e. the Hellenic National Corpus (HNC) and the Greek Web as Corpus (GkWaC).¹

However, the wealth of semantic, contextual and stylistic evidence gleaned from the corpora is not sufficient for compiling a valuable dictionary entry; rather, a sound theoretical basis is necessary for linguistically justifying meaning discrimination. Promising theoretical perspectives in this respect are frame semantics and the cognitive theory of metaphor and metonymy. In this light, I propose a new skeletal structure for the πετάω entry, which (a) groups corpus-attested (self-motion) uses into sense divisions on the basis of existing frame descriptions in the English FrameNet, and (b) makes them hang together in a motivated and transparent manner by means of metaphor and metonymy.

The paper concludes with the suggestion that Greek dictionaries should integrate guiding devices into the long entries of polysemous headwords, a practice pioneered by English learners' dictionaries.

2. The treatment of πετάω in two comprehensive dictionaries of Modern Greek

A mere glance at the *AKN* and *ANEF* entries for πετάω (see Figure 1) reveals that the two dictionaries differ in the presentation of the two main sense divisions of the verb, i.e. flying and throwing; the self-motion and the cause-motion uses are treated under separate entries in *AKN* but within a single entry in *ANEF*. The scope of the present study is restricted to the self-motion network of the verb, and Table 1 has been drawn to summarize the main information provided by the two dictionaries.

More precisely, the middle column of Table 1 uses English metalanguage to give an overview of the relevant sense divisions in the two entries. Whereas both of them record the motion of winged creatures as the first sense, minor or major differences are spotted between the other senses. For example, motion of aircrafts and passengers forms a single sense in *AKN* but two in *ANEF*, which additionally makes special mention of the use of πετάω with regard to pilots. The last more specialized

¹ On the basis of the form lemmatized in the HNC and the GkWaC, this work uses πετάω as the headword form of the lemma rather than πετώ. On the contrary, existing dictionaries which are not corpus-based lemmatize the abbreviated form (see Figure 1).

senses appear in only one of the two entries, but even when uses are recorded by both dictionaries they may be ordered or labeled differently; in this respect, consider the “be efficient” and “move very quickly” senses.

More confusion is created when we compare the two entries as to the multi-word expressions (MWEs) recorded, the place in which they appear (i.e. under which sense), and the way they are presented (i.e. as subentries or examples, with a definition or a cross-reference). For instance, in *AKN* we find *πέταξε το πουλί* under the first sense with the label «φράση» and with a cross-reference to the *πουλί* entry. By contrast, this MWE appears in *ANEF* in a slightly different form (i.e. *πέταξε το πουλάκι*), and under the metaphorical use of the verb in the context of missed opportunities; in *ANEF* the phrase is defined, exemplified, and highlighted as a subentry.

Table 1 *AKN* vs. *ANEF*: An overall picture of the treatment of *πετάω* in its self-motion uses

On the whole, the entries reviewed seem to complement each other in coverage, and to make different decisions about lumping/ splitting, ordering and labelling the self-motion uses of *πετάω*. In addition, the comparison of the two entries raises the issue of phraseological treatment; differences in the form, location and prominence of MWEs should be related to the fact that they are not as fixed as thought to be, and that computerized language corpora are not used by either of the dictionaries for identifying normal patterns of usage. These observations emphasize the need for a systematic and unified lexicographic treatment of polysemy and phraseology. To this end, I propose determining senses on the basis of corpus data and linguistic theory, and employing user-friendly guiding devices to represent them.

3. An integrated approach to word sense disambiguation

With a view to systematizing the lexicographic task of meaning discrimination, we should first specify the basic unit of description. Following Cruse (1986: 77), I do not use the word as a semantic unit but split it into lexical units (LUs) which constitute “the union of a lexical form and a single sense”; a LU “must be at least one semantic constituent” and “at least one word” (*ibid.*: 24). Keeping in mind that a single set of criteria should be used for identifying LUs irrespective of whether they are single-word or multi-word ones, I now proceed to outline the methodology devised for establishing LUs (see Table 2).

corpus-based	context disambiguates: identification of recurrent patterns of usage in concordances
frame-driven	polysemy = one word → several frames → several LUs
cognitive-oriented	polysemy = a process motivated by metonymy/ metaphor

Table 2 Establishing LUs: An integrated approach to word sense disambiguation

The first step in the process involves observing concordance lines for the target word, clustering them according to their common features, and identifying recurrent (and hence normal) patterns of usage (Moon 1987: 87; Hanks 2004: 246-251; Kilgarriff 2008: 145; Atkins & Rundell 2008: 311-312); that is why the approach is characterized as based upon corpus evidence. However, the clusters of data are not self-explanatory; rather, their analysis and interpretation needs to be driven by linguistic theory.

To this end, I employ frame semantics to decide whether a pattern qualifies for the status of a LU; separate senses generally correspond to different semantic frames (Atkins, Rundell & Sato 2003: 335-337; Atkins 2008: 256-257). In brief,

- a (semantic) frame is a structured background of experience which constitutes a kind of prerequisite for understanding the meaning of a word (Fillmore 1985: 224);
- frame semantics links situation-specific semantic roles, i.e. frame elements (FEs), to their syntactic realizations (Fillmore & Petruck 2003: 359); and
- FrameNet is an online lexical resource for English which is applying frame semantics to corpus data, and is still under development (Ruppenhofer et al. 2010: 5).

Several steps have been taken to investigate the applicability of FrameNet to other languages (German, Spanish, Japanese),² and it is generally argued that English FrameNet frames can be reused for the semantic analysis of other languages (Boas 2005; Burchardt et al. 2009; Subirats 2009). In this light,

² No similar large-scale frame-semantic analysis is currently available for Modern Greek.

the present study on *πετάω* draws on English FrameNet and demonstrates its valuable contribution to the creation of a well-structured entry in Modern Greek.

Lastly, to lend further support to the frame-driven sense distinctions, I consider whether they are motivated by cognitive mechanisms (i.e. metonymy, metaphor) and interrelated by means of a semantic network (Lakoff & Johnson 1980, 1999; Van der Meer 1999; Nikiforidou 1999). This network is organized around the synchronically prototypical sense, from which other senses are naturally derived with varying degrees of relatedness. This approach is also related to Evans's (2005: 41) cognitive-oriented model of "principled polysemy", according to which each sense of a polysemous word must contain additional meaning, and manifest specific collocational patterns and/or grammatical structures. However, the present methodology differs from Evans's (2005) model in two respects: (a) first, as already explained, the meaning criterion is defined in frame-semantic terms as involving additional or different FEs, and (b) second, corpus data determine the process rather than merely exemplify senses.

4. Exploiting available corpora

If we consider the recent observation that "there is still a lack of large reference corpora for languages other than English" (Williams 2008: 258), we can appreciate the significance of the development of a national corpus of Modern Greek (the HNC), and recognize the need to consolidate its use in lexicography. The HNC is a monitor corpus of over 47 million running words of texts written in Greek after 1990, and although it may not be truly comparable to English corpora in terms of size or balance, it can facilitate empirically grounding Modern Greek lexicography.

On account of practical issues that determine corpus research, i.e. availability, representativeness, and dependency on software tools, the present work of compiling a new entry for *πετάω* exploits an additional corpus as a secondary source of data. The GkWaC is larger than the HNC,³ and is accessed through a state-of-the-art query system, the Sketch Engine.⁴ This corpus can complement the HNC in terms of both content and functionality. On the one hand, we can test how well less frequent HNC patterns hold up in a larger Web corpus (Renouf 2007: 43), and on the other hand, the Sketch Engine (unlike the HNC query system) automatically derives lexical profiles, the Word Sketches, which can serve as a starting point for distinguishing senses (Kilgariff et al. 2008: 297; Atkins & Rundell 2008: 110).

Figure 2 The GkWaC Word Sketch for *πετάω* – truncated screenshot (May, 2010)

³ The GkWaC contains about 100 million words, and has been constructed by downloading texts from the Internet.

⁴ The Sketch Engine software can load a corpus of any language (with appropriate linguistic mark-up), and offer "word sketches, thesaurally similar words, and 'sketch differences', as well as the more familiar [query] functions" (Kilgariff et al. 2008: 299).

Figure 2 shows a truncated screenshot of the GkWaC Word Sketch for *πετάω*; if these statistically salient collocates are first examined, it is easier to identify separate senses when scanning the HNC sentences. However, Word Sketches should not be taken at face value, because tagging errors are traced; consider, for example, *κάλαθος* in the “object” list and *σύννεφο* in the “subject” list.⁵

5. A new skeletal structure for the self-motion network of *πετάω*

The results of applying the proposed corpus-based, frame-driven, and cognitive-oriented methodology to *πετάω* are summarized in Table 3. The Table presents a coherent account of the self-motion network of *πετάω* in 5 columns. For each LU the 1st column provides one or two corpus-attested sentences which are considered typical illustrative examples of the particular LU; note that the underlines, which indicate the various collocates of *πετάω*, make it abundantly clear that each LU exhibits distinct collocational patterns. The 2nd column specifies the semantic frame evoked by the LU on the basis of the FrameNet descriptions. The 3rd one provides an informal description of the meaning of the LU in English metalanguage. The 4th column employs the cognitive theory of metaphor and metonymy to explain the non-arbitrary relationship between the semantic extensions of *πετάω*; and the last one shows how this motivated semantic network can be reflected in the skeletal structure of a dictionary entry.

Corpus-attested examples	Frame	Sense	Motivation	Structure
- Στο πλάι μας <u>πετούν</u> <u>γλάροι</u> . - Πολεμικά <u>αεροπλάνα</u> <u>πετούν</u> στον ουρανό με βαρύ φορτίο.	[Self_motion] ⁶	move through the air in a controlled manner using aerodynamic forces	core meaning: the primary manner of motion of a bird and an aircraft	1
Κάθε λεπτό 400.000 <u>άνθρωποι</u> <u>πετούν</u> πάνω από την Ευρώπη σε σύνολο 3.500 πτήσεις.	[Ride_vehicle] ⁷	travel by plane	metonymy : CONTENT (passengers) FOR CONTAINER (aircraft)	2a
- Πείτε στον <u>πιλότο</u> , να <u>πετάξει</u> κατ' ευθείαν για το Κάουνας. - Στις Ηνωμένες Πολιτείες, οι <u>πιλότοι</u> που <u>πετούν</u> τα <u>αεροσκάφη</u> του προέδρου επιλέγονται μέσα από ειδικές διαδικασίες.	[Operate_vehicle] ⁸	operate an aircraft	metonymy : CONTROLLER (pilot) FOR CONTROLLED (aircraft)	2b
Στη Χιλή οι <u>αεροπορικές εταιρείες</u> δεν θα <u>πετάζουν</u> το βράδυ της Πρωτοχρονιάς, γιατί οι επιβάτες φοβούνται.	[Operating_a_system] ⁹	provide flight service	metonymy : CONTROLLER (owner: airline company) FOR CONTROLLED (aircraft)	2c
- Τα <u>δόντια</u> μου δεν <u>πετάνε</u> τόσο όταν	[Path_shape] ¹⁰	continue upwards further than the	metonymy : fictive motion	3

⁵ If we examine the hyperlinked concordances, we will see that both *κάλαθος* and *σύννεφο* are objects of PPs.

⁶ FrameNet: “The SELF_MOVER, a living being, moves under its own power in a directed fashion, i.e. along what could be described as a PATH, with no separate vehicle.”

⁷ FrameNet: “In this frame a THEME is moved by a VEHICLE which is not directly under their power. The SOURCE, PATH, GOAL, or AREA of the motion may be indicated. The DISTANCE travelled or the SPEED of motion may also be indicated. A ROUTE or ROAD may be present and the MANNER in which the THEME moves may be given.”

⁸ FrameNet: “The words in this frame describe motion involving a VEHICLE and someone who controls it, the DRIVER. Some words normally allow the VEHICLE to be expressed as a separate constituent.”

⁹ FrameNet: “An OPERATOR manipulates the substructure of a SYSTEM such that the SYSTEM performs the function it was created for.”

¹⁰ FrameNet: “The words in this frame describe the ‘fictive’ motion of a stationary ROAD.”

χαμογελάω. - Το <u>μαλλί</u> του <u>πέταγε</u> σαν λοφίο.		main part of an object	MANNER OF MOTION ALONG THE PATH FOR CONFIGURATION OF THE PATH	
- Το <u>αυτοκίνητο</u> <u>τρέχει</u> , <u>πετά</u> . - Το <u>δολάριο</u> <u>πετά</u> στα ύψη. - <u>Πετάει</u> η ομάδα.	[Change_position_on_ a_scale] ¹¹	increase in speed/ value/ performance	metaphor: MORE IS UP (GOOD IS UP)	4
- <u>Πετάξα</u> από τη χαρά μου. - Λογικό μοιάζει άλλωστε να <u>πετούν</u> <u>στα σύννεφα</u> ύστερα από μια τέτοια επιτυχία.	[Experiencer_focus] ¹²	feel light with happiness	metaphors: EMOTION IS MOTION, HAPPY IS UP	5
- Η <u>ευκαιρία</u> ήταν μεγάλη, αλλά... <u>πέταξε</u> . - Και όταν αποφάσισε να κάνει αλλαγές, <u>το</u> <u>πουλάκι</u> <u>είχε πετάξει</u> .	[Departing] ¹³	used for saying that you have missed the chance to do something	metaphor: GENERIC IS SPECIFIC experiential grounding: image of a bird flying away	6
Δικαίωμα του δημάρχου Ενόγγελου Παπάζογλου, είναι να πιστεύει πως « <u>πετάει ο</u> <u>γάδαρος</u> », όπως δικαίωμά μου είναι να τον αμφισβητώ.	[Likelihood] ¹⁴	used for saying that a belief is irrational	metaphor: GENERIC IS SPECIFIC experiential grounding: donkeys (having no wings) cannot normally fly	7

Table 3 The self-motion network of *πετάω*

Unlike *AKN* and *ANET*, which assign different senses to the use of *πετάω* in the context of winged creatures and aircrafts, I lump them together within the 1st LU because the same frame, [Self_motion], is evoked, and because the manner of motion denoted is primary for both birds and aircrafts; the similarity of the examples in terms of syntactic structure (i.e. + AREA PP) lends further support to this decision. When the corpus examples evoke a set of FEs that differs from the [Self_motion] one evoked prototypically, we are dealing with a separate LU which is associated with the core one via cognitive mechanisms. More precisely, the next three LUs evoke the frames [Ride_vehicle], [Operate_vehicle] and [Operating_a_system], as indicated by the collocate types in subject position, i.e. passenger, pilot and airline company respectively. Unlike *AKN* and *ANET*, the proposed skeletal structure groups these LUs together under sense 2, in order to show that they are all derived from the 1st one through different types of conceptual metonymy. Also note that the 2c use observed in the corpus data is missing from both *AKN* and *ANET*. The next LU evokes the [Path_shape] frame which is used to describe the fictive motion of a stationary ROAD; in this case, the FE ROAD is a body part in protruding position. Although this LU is also related to LU1 by metonymy, it is presented as sense 3 rather than as 2d because it has nothing to do with aircrafts.

¹¹ FrameNet: “This frame consists of words that indicate the change of an ITEM’s position on a scale (the ATTRIBUTE) from a starting point (INITIAL_VALUE) to an end point (FINAL_VALUE). The direction (PATH) of the movement can be indicated as well as the magnitude of the change (DIFFERENCE). The rate of change of the value (SPEED) is optionally indicated.”

¹² FrameNet: “The words in this frame describe an EXPERIENCER’s emotions with respect to some CONTENT. A REASON for the emotion may also be expressed. Although the CONTENT may refer to an actual, current state of affairs, quite often it refers to a general situation which causes the emotion.”

¹³ FrameNet: “An object (the THEME) moves away from a SOURCE. The SOURCE may be expressed or it may be understood from context, but its existence is always implied by the departing word itself.”

¹⁴ FrameNet: “This frame is concerned with the likelihood of a HYPOTHETICAL_EVENT occurring. The HYPOTHETICAL_EVENT is its only core frame element.”

Table 3 arranges senses in a continuum from physical to metonymic to metaphorical motion. The last four LUs are metaphorically motivated by [Self_motion], and evoke the frames [Change_position_on_a_scale], [Experiencer_focus], [Departing] and [Likelihood]. Two points are worth noting in this respect. First, by using semantic frames and conceptual motivation as criteria for clustering corpus examples into LUs, we achieve a coherent treatment of metaphorical uses that are scattered over various places in the entries reviewed; consider senses 4 and 6 in particular. Second, note that in combining semantic and contextual criteria for determining LUs, we should pay particular attention not to elevate mere contextual variations to the status of a LU. Therefore, each one of the MWEs in 4, 5 and 6 (i.e. *πετάει η ομάδα*, *πετάω στα σύννεφα*, *το πουλάκι έχει πετάξει*) is not treated as a stand-alone LU, since it does not evoke a distinct frame. By contrast, the last MWE *πετάει ο γάιδαρος*, which appears under the 1st core sense in both *AKN* and *ANEF*, fulfills the criteria for a separate LU.¹⁵

6. Suggestions for enhancing user-friendliness

A lexicographic analysis along these lines can improve not only the content but also the presentation of the long entries of polysemous headwords.

For example, semantic frames can be used for presenting senses as menus at the top of entries and/or as signposts at the beginning of definitions within entries. The semantic order approach, according to which literal senses precede figurative ones in entries, can help users form a coherent picture of the various uses of a word. User-friendliness can also be achieved by employing a tiered structure for conventional metonymic extensions, by adding usage notes and in particular metaphor boxes, and by foregrounding co-occurrence patterns by means of eye-catching devices (like font and highlighting).

English learners' dictionaries have paved the way for devising such guiding principles to make long entries easier to navigate, and to enhance users' language awareness. For instance, metaphor boxes have been integrated in the *MEDAL* dictionaries (print and electronic; 2002, 2007) (Moon 2004).

7. Concluding remarks

The present study has shown that Modern Greek lexicography can be systematized and modernized in the following ways:

- by combining empirical evidence (i.e. corpus data) with semantic theory, and thus using linguistically-informed judgment for making sense of the evidence rather than creating it;
- by recognizing the importance of establishing LUs in making precise (monolingual) descriptions;
- by drawing on existing frame-semantic resources to enrich current dictionary entries and to accelerate the process of establishing LUs;
- by using the cognitive mechanisms of metaphor and metonymy to make LUs hang together in a motivated and transparent manner.

These guidelines have considerable implications for training lexicographers.

ABSTRACT

This is a corpus-based study of the morphological productivity of the Greek verb-forming element -pió, treated here as an affixoid, gradually acquiring a suffixal status. Its productivity is measured in a corpus of 4,143,583 words (a part of the Corpus of Greek Texts) in relation to that of eight Greek verb-forming suffixes studied in Efthymiou et al. (2012). The results suggest that -pió's productivity is similar to that of the moderately productive suffixes -évo and -áro. It is also found to be more productive in written registers, while it presents its highest productivity in opinion articles and its lowest one in literature.

Keywords: corpora, frequency, Modern Greek, morphological productivity, *-pió*, text types, verb-forming elements

1. Introduction

This paper aims at exploring the productivity of the Modern Greek verb-forming element *-pió* in a subcorpus of the Corpus of Greek Texts (CGT), a reference corpus of Greek (see Goutsos 2010). We follow similar research on other languages, investigating frequency and morphological productivity with a corpus-based methodology (e.g. Baayen & Lieber 1991, Baayen 1992, Plag et al. 1999, Gaeta & Ricca 2003). This is part of a larger project studying the productivity of verb-forming elements, based on a large corpus of Modern Greek. Although *-pió*'s morphological status is debatable (i.e. whether it is a suffix or not), in the present study we treat this element as an affixoid moving towards acquiring a suffixal status, an element which is in a process of grammaticalization, becoming a suffix, according to relevant observations in the literature (see Anastassiadis-Symeonidis 1986, Giannouloupoulou 2000). On the basis of this, the morphological productivity of *-pió* is measured here in relation to that of Greek verb-forming suffixes *-áro*, *-éno*, *-évo*, *-íno*, *-ízo*, *-(i)ázo*, *-jázo* and *-óno*, studied in another paper (Efthymiou et al. 2012). This study can offer useful evidence on how productive *-pió* is in relation to the productivity of well-established suffixes. Here, a comprehensive productivity profile of *-pió* is attempted to be drawn by the examination of its productivity across written and spoken texts, as well as its productivity patterns across the five largest text types in the corpus (i.e. literature, news, popularized non-fiction, academic and opinion articles).

In summary, this paper aims at answering the following research questions:

- (a) How productive is *-pió* in relation to the productivity scores of the eight verb-forming suffixes mentioned above?
- (b) Is *-pió* equally productive across spoken and written registers?
- (c) Is *-pió* more productive in certain text types?

The paper is organized as follows. The following section presents the main properties of the element under investigation, while section 3 is dedicated to a brief overview of the relevant literature

on the notion of productivity. In section 4 we explain how the data of this study was selected and outline the methodology used for data analysis. Section 5 describes the results of the research and section 6 discusses and summarizes the findings, along with drawing the implications of the study.

2. The Modern Greek verb-forming element *-pió*: morphological properties and status

In this section we outline the properties of the Modern Greek verb-forming element *-pió*, based on Anastassiadis-Symeonidis' (1986), Giannouloupoulou's (2000), Mela-Athanasopoulou's (2007) and Efthymiou's (2011a) analysis, and discuss its morphological status. For the semantic description of the derived verbs we will use the labels and glosses found in Plag (1999), namely causative/resultative 'cause to become x/turn into x', ornative 'make x go to/in/on something', locative 'make something go to/in/on x', inchoative 'become x', performative 'do x/perform x', similitive 'act or be like x', instrumental 'use x' and stative 'be x' (see also Lieber 2004).

2.1 The structural and semantic properties of *-pió*

Historically, the bound Modern Greek morpheme *-pió* developed from the Ancient Greek verb *poiô* 'to make/do' (cf. Triandafyllidis Dictionary 1998). According to the literature, the verb-forming element *-pió* attaches both to nominal and adjectival bases. Interestingly, the majority of its adjectival bases are relational adjectives in *-ikós*. All *-pió* formations are transitive verbs and their meanings can be described as resultative, locative and ornative, as seen in example 1:

(1)	a.	<i>aplopió</i> 'simplify'	<i>aplós</i> 'simple'
	b.	<i>elaçistopió</i> 'minimize'	<i>elaçistos</i> 'minimal'
	c.	<i>stereopió</i> 'solidify'	<i>stereós</i> 'solid'
	d.	<i>gramatikopió</i> 'grammaticalize'	<i>gramatikós</i> 'grammatical'
	e.	<i>prosopopió</i> 'personify'	<i>prósopo</i> 'person'
	f.	<i>periθoriopió</i> 'marginalize'	<i>periθório</i> 'margin'
	g.	<i>omadopió</i> 'divide into groups'	<i>omáda</i> 'group'
	h.	<i>morfopió</i> 'to form'	<i>morfi</i> 'form'

According to Anastassiadis-Symeonidis (1986), *-pió* is extremely productive in forming neologisms with resultative meaning in Modern Greek and thus it enters in competition with other verb forming processes, like the verbal suffixes *-évo*, *-ízo*, and *-óno*. For example, the neologism *elino-pió* 'to turn into a Greek' has begun to replace the older synonymous parasynthetic verb *eks-elin-ízo* (*Élinas* 'Greek'). More specifically, Anastassiadis-Symeonidis (1986) argues that formation with *-pió* is more productive than parasynthetic verb formation for the following reasons:

a) *-pió* is less sensitive to phonological, morphological and lexical restrictions than Modern Greek verb-forming suffixes,

b) *-pió* formations are more transparent and predictable in meaning than parasynthetic formations (for the semantic description of the Modern Greek parasynthetic formations see Tsakou 2010 and Efthymiou 2011b),

c) *-pió* is more likely to be phonotactically signalled because of the presence of the linking vowel *-o-*. This argument accords with Hay (2000), who argues that consonant-initial suffixes are more productive than vowel-initial ones, because they are more likely to provide phonotactic boundary signals.

In addition, Anastassiadis-Symeonidis' claim about the predictability of *-pió* is in line with Efthymiou (2011a, 2001b), who argues that the meanings of *-pió* verbs are much more restricted than the meanings of Modern Greek parasynthetic or suffixed verbs. As already mentioned, *-pió* verbs are restricted to resultative, ornative and locative meanings, whereas suffixed or parasynthetic verbs can also express other meanings, such as similitive, performative or privative meanings (e.g. *piθicízo* 'to imitate ape's behaviour', *apo-cefal-iz-o* 'to decapitate', *xorévo* 'to dance'). Finally, this observation also accords with Mela-Athanasopoulou (2007), who observes that inchoative meanings are only possible with the passive voice of *-pió* verbs.

2.2 The morphological status of *-pió*

According to several studies (e.g. Anastassiadis-Symeonidis 1986, Giannouloupoulou 2000, Ralli 2005, Dimela 2010), *-pió* is an affixoid, i.e. an element that shares properties both with derivation and compounding.¹ An affixoid is neither a stem nor an affix but is an element that is in process of being grammaticalized, gradually losing its lexical status as a stem and behaving more or less like an affix. The basic arguments found in the literature for treating *-pió* as an affixoid are the following:

a) Its homonymous free form has lost its independent status in Modern Greek. The use of the free form *pió* is restricted to fixed or archaic expressions.

b) There exist a few verbs in which *-pió* is a compound element and combines with prefixes (e.g. *ek-pió* ‘to sell up’, *para-pió* ‘to counterfeit’). Nevertheless, all these forms are [+learned] verbs, which originate from Ancient Greek.

c) The Modern Greek bound element *-pió* expresses more meanings than the homonymous Ancient Greek free form *poiô* ‘to do/make’.

d) A considerable number of Modern Greek *-pió* verbs, which are mostly used in academic terminology, are loan translations of English (or French) suffixed verbs (e.g. *gramatikopió* ‘to grammaticalize’).

e) *-pió* is not phonologically reduced or fused with its base. Furthermore it is phonotactically signalled because of the presence of the linking vowel *-o-*, which is found only in compounding.

Based on the above mentioned phonological, semantic and structural properties, *-pió* can be considered an affixoid, moving towards acquiring a suffixal status but still displaying no phonological attrition (see Anastassiadis-Symeonidis 1986 and Giannouloupoulou 2000 for details). In other terms, if compounding and derivation are thought of as the two poles of a morphological continuum, *-pió* is placed closer to suffixation and can be regarded as a suffix-like element.²

3. Morphological productivity

Morphological productivity is a central issue in the field of derivational morphology, since its measurement can help us describe the current and/or future involvement of a word formation process in the coinage of new words (cf. Bauer 1983: 18, Plag 2003: 44). The relevant literature has studied morphological productivity following different approaches, mainly qualitative or quantitative. This variety of approaches is justified by the different aspects of morphological productivity itself. According to Corbin (1987), productivity can be divided into two distinct phenomena: availability (translation of the French term “disponibilité”, referring to how available a morphological process is to produce new words,) and profitability (translation of the French term “rentabilité”, referring to how exploitable a morphological process is in order to create new words). In this sense, availability is a qualitative notion, since a morphological process is either available or not (Bauer 2001: 205), whereas profitability is a quantitative notion, since it reflects the extent to which a morphological process may be exploited to create new forms (cf. Plag 2006).

Qualitative approaches usually deal with various kinds of restrictions (i.e. structural, pragmatic, psycholinguistic etc.; see e.g. Plag 1999, Rainer 2005) that take part in word formation, while quantitative approaches deal with frequency and probability. As frequently observed, there is an inverse correlation between the number of restrictions and the productivity of a word formation process: the more restrictions apply, the fewer words will be derived (Booij 1977, Lieber 2010). This interrelation of qualitative and quantitative aspects of productivity, which is also observed by Plag (1999: 22), suggests that both quantitative and qualitative approaches have to be taken into consideration when talking about productivity (cf. e.g. Aronoff & Fudeman 2011, Plag 2006).

In this paper we explore the productivity of *-pió* mainly in quantitative terms. In particular, we follow Baayen and his collaborators (e.g. Baayen 1993, Baayen & Lieber 1991), who have proposed quantitative measures of productivity, defined with respect to the frequency of a given word-formation process. This frequency is measured in terms of “type frequency”, i.e. the number of different words that occur with the morphological category of *-pió* (e.g. *nomimopió* ‘to legitimate’, *xrisimopió* ‘to use’

¹ Other terms, which are frequently used by linguists in order to account for these borderline cases, are semi-affixes, affix-like elements, lexical suffixes or confixes (see, among others, Anastassiadis-Symeonidis 1986, Giannouloupoulou 2000, Ralli 2005, Mela-Athanasopoulou 2007).

² On the morphological continuum of compounding and derivation see Dalton-Puffer & Plag (2001), Ralli (2005) and Dimela & Melissaropoulou (2009), among others.

and *dimosiopió* ‘to publish’ are three types of the morphological category *-pió*, and “token frequency”, i.e. the actual number of occurrences within the morphological category of *-pió* in a given text (e.g. *dimosiopió* ‘publish_{1st.pers.sing.pres.}’ and *dimosiopiís* ‘publish_{2nd.pers.sing.pres.}’ count as two occurrences, i.e. tokens, of the morphological category *-pió*).

Baayen and his collaborators (e.g. Baayen 1992, 1993, 2001, cf. also Baayen & Lieber 1991, Baayen & Renouf 1996, Plag et al. 1999) have elaborated a number of distinct and complementary corpus-based statistical measures of productivity, which all rely on the availability of large electronic text corpora. These measures can be operationalized by the concept of vocabulary growth, i.e. how frequently new word types that are formed by a morphological process are encountered when an increasing amount of text is sampled (Baayen 2001). This study relies on two well-known measures of morphological productivity proposed in this probabilistic framework.

One of Baayen’s measures is termed “realized productivity”. It is given by the number of word types V (or the vocabulary size) of a morphological category C , in a corpus of N tokens:

$$V = V(C, N)$$

This measure is also known as “type frequency” or “extent of use” (cf. Baayen 2008a, Plag 2006). According to Bauer (2001), realized productivity is restricted to past achievement (cf. Baayen 2008a) and cannot provide information as to whether a certain morphological process is available or not.

Another measure proposed by Baayen, known as “potential productivity”, relies on the notion of “hapax legomenon”. Hapax legomena (or hapaxes) are the types that occur only once in a corpus. The rate at which a vocabulary grows can be captured by the proportion of hapax legomena to the total number of tokens $N(C)$ of all words with the morphological category C . Thus, potential productivity is given by:

$$P = V(1, C, N) / N(C)$$

According to Baayen and Lieber (1991), this ratio estimates the rate at which new types of a given morphological category are to be expected, given that the size of the sample of relevant observed types equals $N(C)$. This type of productivity, also called “productivity in the narrow sense” (cf. Plag 1999), serves to estimate the rate at which a morphological category enriches the vocabulary. The rate at which new types appear in the corpus can be visualized via a vocabulary growth curve. This curve reports vocabulary size (number of types, V) as a function of sample size (number of tokens, N) and P can be also seen as the slope of the tangent to this curve at N (Baayen 2001: 49-50).

However, potential productivity has been subjected to criticism (Baayen 1993, Bauer 2001) for ignoring type frequency and due to the fact that, since P is itself a function of N , its value depends on the size of the sample of the corpus. It is therefore problematic to compare directly a small subcorpus with a large subcorpus without distortion, due to the substantial differences in the overall sizes of the subcorpora and the substantial differences in V and P (Plag et al. 1999, Baayen 1992, 2008b). Fortunately, there are two ways to overcome this problem (Baayen 2008c: 272-274). The first is to compare the number of types across texts for the same text sizes. For larger texts, a random sample of the same size as the smallest text in the comparison has to be selected. The second way is to resort to models of vocabulary growth, especially developed for this purpose (see Baayen 2001 for an overview of these models).

4. Data and methodology

The data used for the measurement of productivity of *-pió* comes from the Corpus of Greek Texts (CGT), a synchronic and monolingual corpus of Modern Greek, including approximately 28 million words from a variety of spoken and written text types. (For more details on the corpus, see Goutsos 2010). For the aims of this study a subcorpus of the CGT (henceforth CGT4) was created by randomly selecting 4,155,036 words. The measurement of productivity in a corpus smaller than the CGT was considered as more manageable, since CGT is not tagged (e.g. morphologically or for parts of speech) and, consequently, the extraction of the verbs formed by *-pió* could only be done by manual pre-processing. CGT4 was stratified by text type, both spoken (conversation, interviews, news, public speech) and written (information items, law and administration texts, literature, anecdotes, popularized non-fiction texts, news, opinion articles, academic texts, private texts, such as private letters, electronic texts, diary, ephemera and procedural texts etc). All text types found in the CGT are represented in the CGT4, in the same proportion in which they occur in the former. It is also worth noting that all texts contained in the CGT4 are in Standard Modern Greek. Table 1 below presents the number of words and the percentage of the text types in CGT4.

Text type	Number of words	Percentage
Conversation	17,867	0.43
Interview	98,059	2.36
News (spoken)	44,874	1.08
Public speech	296,254	7.13
<i>Spoken (Total)</i>	<i>457,054</i>	<i>11.0</i>
Information items	16,620	0.40
Law and administration	186,145	4.48
Literature	382,263	9.20
Private	13,711	0.33
Popularized non-fiction	1,289,724	31.04
News	677,272	16.30
Other	55,262	1.33
Academic	633,643	15.25
Opinion articles	443,342	10.67
<i>Written (Total)</i>	<i>3,697,982</i>	<i>89.0</i>

Table 1 Size of text types in the CGT4

As can be seen in Table 1, the percentage of spoken data (11% of the corpus) is much lower than the percentage of written data (89% of the corpus). In addition, the percentages of the specific text types differ largely: for example, public speeches occupy approximately two thirds of the spoken corpus, while conversation hardly occupies one half percent out of the total 11% of the spoken corpus.

First, a frequency list of all words in the corpus was made using the wordlist function of Wordsmith Tools 5.0 (Scott 2008). The list was sorted in reverse alphabetical order (so that tokens with the same ending were clustered together) and all verbs formed by *-pió* were then manually identified. It is important to note that we did not search for the participles of *-pió* verbs, excluding thus from the list the (usually rare) periphrastic types of the present perfect and past perfect in the passive voice (*ime* ‘to be’ + past participle). This choice was also theoretically driven, since the inclusion of these periphrastic types in the tense system of Greek is controversial.³

After the compilation of the list, items with a problematic status were removed, following a standard procedure in the literature (see e.g. Plag 1999: 28-29, Plag et al. 1999: 214, Fradin et al. 2008: 38ff.). In particular, all verbs displaying derivational inner cycles, i.e. derived by prefixation (e.g. *apostaðero-pió* ‘to destabilize’) and composition (e.g. *proto-xrisimo-pió* ‘to use for the first time’) were excluded. Items which fall into the category of “base-less derivatives”, as Gaeta and Ricca (2003: 71) call them, were also removed from the lists. For instance, the verb *posostiko-pió* ‘to quantify’ was excluded, since its base **posostiko-* does not exist as such in Greek; this is rather a merging of *posotikós* and *posostó*. In addition, items “semantically opaque but formally analyzable” in terms of Plag et al. (1999: 214), such as *ikano-pió* ‘to satisfy’, which cannot be semantically related to the adjective *ikanós* ‘capable’, or *tropo-pió* ‘to modify’, which cannot be semantically related to the noun *trópos* ‘means’, were also excluded from the final list. Finally, a few verbs in which *-pió* is a compound element, combining with prefixes, such as *ek-pió* ‘to sell up’, *para-pió* ‘to counterfeit’ and *meta-pió* ‘to remake/to alter’, were not included. It is interesting to note that the majority of the types removed from the list were verbs derived by prefixation.

The application of these criteria reduced the number of tokens under study. Details for the number of tokens in the raw data, i.e. the total number of tokens in the corpus before clearing the data, are given in Table 2.

Suffixes	Raw data	Data after clearing		
	Tokens	Tokens	Types	Hapax legomena
<i>-pió</i>	6,195	5,130	132	40

Table 2 Frequencies in raw data and after clearing

³ See, for example, Moser (1994: 140ff.), where it is supported that these structures in Standard Modern Greek are mainly stative predicates, something which means that they are not principally used for tense distinctions.

The tokens selected for the study were manually lemmatized and the number of hapax legomena was counted. The number of types, as well as the number of hapaxes found in the data included in the study, is also shown in Table 2. The selected tokens and types of *-pió*, as well as its hapaxes, were searched in the corpus as a whole, in the written and spoken registers and in each individual text type included in the CGT4. This search can offer valuable information about the relation of the productivity of *-pió* to written and spoken registers and text types.

The substantial differences in the overall size of the subcorpora (see Table 1) prompted us to resort to a family of parametric statistical methods, called Large-Number-of-Rare-Events (LNRE) models (for an overview see Baayen 2001). LNRE models can be used to quantify the relative productivity of two or more morphological processes by looking at their vocabulary growth rate as sample size increases. An LNRE model attempts to estimate the expected number of types (the vocabulary size) both at smaller sample sizes (interpolation) and at larger sample sizes (extrapolation), based on the counts of low frequency types in the corpus (the frequency spectrum). The technique of extrapolation produces the expected values of types for arbitrary values of tokens, larger than the empirical number of tokens. Currently, three major models are available: Generalized Inverse Gauss-Poisson (GIGP; Baayen 2001), finite Zipf-Mandelbrot and Zipf-Mandelbrot (fZM and ZM; Baroni & Evert 2006). These models are implemented in the package zipfR (Baroni & Evert 2006), a tool for lexical statistics in the R language, which is used in this study.

In order to address research question (a), regarding the productivity of *-pió* as compared to that of the eight Greek suffixes, an appropriate LNRE model is first computed and a corresponding growth curve is obtained for the suffix with the highest number of tokens (*-ízo*). Then, this model is used to extrapolate the growth curves of the other suffixes up to the size of *-ízo*. The appropriateness of each model for the data is assessed by a multivariate goodness-of-fit test (Baayen 2001: 118-122). To further assess model fit, the observed frequency spectrum of each suffix and *-pió* is compared with the fitted model predictions. The growth curves are graphed for 100 equally sized intervals and 95% confidence intervals are plotted around the curves. A 95% confidence interval for V gives the range of values that V is most likely to have when calculated for new corpora of the same design and size.

The difference in productivity of *-pió* across spoken and written registers (research question b), is explored in a similar manner to (a). The growth curves of *-pió* are plotted for 40 equally sized intervals up to the number of tokens sampled for it in the written subcorpus, the largest subcorpus of the CGT4. The growth rates P of the vocabulary are calculated for both the largest and the smallest sample size.

The investigation of differences in suffix productivity across different text types (research question c) is only relevant for the five largest text types in the CGT4 (literature, news, popularized non-fiction, academic and opinion articles). For the remaining text types, there are cases where the number of different tokens and types are not sufficient to fit an LNRE model or the model fit is not acceptable. In this context, an appropriate LNRE model is computed for each text type in the interval [1, 15316].

5. Results

The morphological productivity of *-pió* has been measured in relation to that of the eight verb-forming suffixes (*-áro*, *-éno*, *-évo*, *-íno*, *-ízo*, *-(i)ázo*, *-jázo* and *-óno*) studied in Efthymiou et al. (2012). The vocabulary growth curves of *-pió* and the eight suffixes in CGT4 are presented in Figure 1. The figure illustrates how vocabulary size, i.e. the number of types, shown on the vertical axis, increases as one reads through the tokens of the corpus, plotted on the horizontal axis. The number of types plotted corresponds to the expected vocabulary size $E[V(N)]$, i.e. the number of different types one may expect to count on average for a great many different orderings of the text fragments in a given corpus. A finite Zipf Mandelbrot model was fitted for the majority of suffixes, with the exceptions of *-ízo* and *-évo*, where a Generalized Inverse Gauss-Poisson (GIGP) model performed much better.

Figure 1 The expected number of types $E[V(N)]$ for *-pió* and the eight suffixes in the CGT4 as a function of the size in tokens N of the suffix *-izo* (with 95% confidence intervals)

The growth curves are plotted for 100 equally sized intervals between 1 and 15316, which stands for the number of tokens sampled for *-izo* in the corpus. Figure 1 also plots 95% confidence intervals around the vocabulary growth curves. By means of the resulting vocabulary growth curves, we can easily compare the productivity of *-pió* and the eight suffixes for a range of different values of corpus sizes N (cf. Plag et al. 1999 for a similar approach to some English affixes). Two curves can be regarded as significantly different, if one is outside the confidence interval of the other.

According to our analysis in Efthymiou et al. (2012), there are three main sets of suffixes: (a) the very productive suffixes (*-izo* and *-óno*), (b) the moderately productive suffixes (*-évo* and *-áro*) and (c) the least productive or unproductive suffixes (*-jazo*, *-(i)ázo*, *-éno* and *-ino*). The vocabulary curve of *-pió* is similar to that of moderately productive suffixes. In particular, *-pió* is less productive than *-izo*, *-óno* and *-évo* and more productive than *-jazo*, *-(i)ázo*, *-éno* and *-ino*. The confidence intervals of *-pió* and *-áro* considerably overlap; thus it is difficult to decide which of the two is the most productive.

The results for *-pió* can be considered reliable, since the overall model fit was found to be satisfactory, when further assessed by comparing the observed frequency spectra of *-pió* with the fitted model predictions. A frequency spectrum is the number of types per frequency class, i.e. how many types occur once, twice and so on (cf. Baayen 2001). Figure 2 demonstrates the observed frequency spectrum and the fitted predictions for *-pió*. As the plot indicates, there are evidently some problems, especially at two, six and nine occurrences. These discrepancies can be attributed to possible violations of the randomness assumption of the models or to insufficient sample size. However, the overall fit appears to be satisfactory.

Figure 2 Frequency spectrum for *-pio* alongside predictions of the finite Zipf-Mandelbrot (fZM) model ($\chi^2(3) = 1.44$, $p = 0.742$). The y-axis shows the observed and expected number of types V that occur exactly m times. The plot shows the 15 types with the lowest frequencies.

5.1 Productivity of *-pio* across spoken and written registers

In order to estimate the productivity of *-pio* across the spoken and written registers of the CGT4, we have created the growth curves for 40 equally-sized intervals between 1 and the number of tokens sampled for the suffix in the written subcorpus. According to Figure 3, *-pio* is more productive in written than in spoken registers.

Figure 3 The expected number of types $E[V(N)]$ for *-pio* (calculated by means of the finite Zipf-Mandelbrot (fZM) model) in the written and spoken subcorpora of the CGT4 as a function of the size in tokens N sampled for *-pio* in the written subcorpus (with 95% confidence intervals)

Table 3 shows the potential productivity of *-pio* based on the largest (i.e. written) and the smallest (i.e. spoken) sample size.

Suffix	N(Written)		N(Spoken)	
	Written	Spoken	Written	Spoken
<i>-pio</i>	0.0075	0.0001	0.0559	0.0474

Table 3 Potential productivity of *-pió* across written and spoken registers at different values of *N*

The results are similar with the ones derived from the growth curves: *-pió* is more productive in written than spoken registers, since it presents higher scores in the column “Written” for both points of reference (compare columns “N(Written)” and “N(Spoken)”).

5.2 Productivity of *-pió* across text types

In this section we present a comparison of the contribution of *-pió* to the growth of the vocabulary of the largest written subcorpora in the CGT4, namely literature, news, popularized non-fiction, academic and opinion articles. Figure 3 visualises the growth curves for the five text types. The curves are plotted for 100 equally sized intervals between 1 and 15316, the number of tokens sampled for *-izo* in the corpus. *-pió* tends to yield more types in opinion articles, academic texts and popularized non-fiction, while it is least productive in news and literature. It is also notable that the curve for opinion articles is almost always above the curves for the other text types, which shows the greater potential of *-pió* to form new words in opinion articles.

Figure 4 The expected number of types $E[V(N)]$ for *-pió* in each text type as a function of the size in tokens *N* of the suffix *-izo* (with 95% confidence intervals)

Table 4 shows the potential and realized productivity of the five text types in the interval [1, 15316] in ascending order.

Text types	Potential	Realized
Literature	0.0067	73.67
News	0.0051	79.58
Popularized non-fiction	0.0100	128.92
Academic texts	0.0110	134.06
Opinion articles	0.0133	157.75

Table 4 Realized and potential productivity of *-pió* by text type for $N = 15316$

The results are similar with the ones derived from the growth curves: *-pió* is more productive in opinion articles and less productive in literature. Table 4 also confirms the pattern observed in Figure 4, that *-pió* is more productive in the set of text types including opinion articles, academic texts and popularized non-fiction texts than in the set consisting of news and literature.

6. Discussion and conclusions

As shown in the previous section, the affixoid *-pió* has proven to be a moderately productive verb-forming element, which can be considered to belong to the same set of verb-forming elements as the suffixes *-évo* and *-áro*. More specifically, *-pió* is found to be less productive than *-ízo* and *-óno*, which are the most productive Modern Greek suffixes, and more productive than *-jázo*, *-(i)ázo*, *-éno* and *-ino*. In the set of verb-forming elements with moderate productivity *-évo* stands at some remove from the other members, while the relation between *-pió* and *-áro* is complicated. As observed in section 5 (see Figure 1), the confidence intervals of *-pió* and *-áro* considerably overlap and thus it is difficult to decide which is the most productive. Both verb-forming elements present a rather high number of hapaxes in the data (approximately one third of their types are hapax legomena; see Table 2 for *-pió* and Efthymiou et al. 2012 for *-áro*), something which suggests that the probability of finding new words formed by these elements is very high. Apart from their similarities regarding productivity scores and number of hapaxes, *-pió* and *-áro* are both relatively new verb-forming elements in the history of Greek, which seem to enter in competition with older Modern Greek verb-forming suffixes, such as *-évo*, *-ízo* and *-óno* (see e.g. Anastassiadis-Symeonidis 1986; cf. Efthymiou et al. 2012). They are also both related to the introduction of loan words in Greek, following, however, a different path: *-áro* shows preference for non-native bases (e.g. *tsekáro* ‘to check’, base: *tsek* ‘check’), while *-pió* is frequently used in verbs which are loan translations of English (or French) suffixed verbs. This common characteristic of *-pió* and *-áro* can provide an explanation of their relatively high productivity, taking into account that other suffixes like *-ízo*, which were used in order to accommodate foreign loan words, are also very productive (see Anastassiadis-Symeonidis 1994, Ralli 2011).

Moreover, the attempt to refine the findings on the productivity patterns of *-pió* by looking at its productivity across written and spoken registers, on the one hand, and text types, on the other, has also yielded significant results. As was observed, *-pió* is more productive in written than spoken registers, a finding that can be related to the [+learned] character of the verbs it forms. It is worth noting here that the preference of *-pió* for written registers is not divergent, but is rather common; as our study of Greek verb-forming suffixes has indicated (Efthymiou et al. 2012), only two out of eight suffixes were found to be more productive in spoken than written registers. This result seems to confirm the observation found in the literature that written language is lexically richer than spoken language (Plag et al. 1999; cf. Biber et al. 1999: 53).

Although *-pió* and *-áro* are observed to have similar productivity scores, they show mirror image preferences as regards their productivity in spoken and written texts: *-pió* is more productive in written than spoken registers, whereas *-áro* appears to be more productive in spoken texts. As observed in Efthymiou et al. (2012), the high productivity of *-áro* in spoken texts can be related to the [-learned] or [+/-learned] character of its derivatives, which generally belong to everyday vocabulary, used in spoken interaction (e.g. *frenáro* ‘to brake’). In contrast, *-pió* usually forms verbs with a [+learned] character, which are mostly expected in formal or written texts. The observation that two verb-forming elements with similar productivity scores can show opposite preferences in terms of registers suggests that the study of productivity across spoken and written registers can be very useful in drawing a refined picture of verb-forming elements.

Turning to the productivity pattern of *-pió* across text types, it should be noted that the search was only possible for the five largest text types (i.e. literature, popularized non-fiction texts, opinion articles, news and academic texts), because of the relatively small size of the other text types. As observed in section 5 (see Figure 4), it was found that *-pió* tends to yield more types in opinion articles, academic texts and popularized non-fiction, while it is least productive in news and literature. The study of the particular verbs formed by *-pió* in each text type shows that it is more productive in text types containing a large amount of terminology. For instance, opinion articles, in which *-pió* is most productive, contain many terms related to economy, politics or other social issues such as *refstopió* ‘to liquidate’, *iðiotikopió* ‘to privatize’, *pangozmiopió* ‘to globalize’, *anotatopiúme* ‘to become a University, for Polytechnics’. Similarly, academic texts present a high number of academic terms such as *kanonikopió* ‘to normalize’, *lektikopió* ‘to verbalize’, *fisiolojikopió* ‘to naturalize’, *tiçeopió* ‘to make something accidental’. Popularized non-fiction texts have a wide range of terminology related to various aspects of life (e.g. *eðnikopió* ‘to nationalize’, *astikopió* ‘to urbanize’, *adiavroxopió* ‘to make something waterproof’), as well as evaluative vocabulary such as *iroopió* ‘to turn someone into a hero’ and *periðoriopió* ‘to marginalize’. Finally, news and literature abound in everyday vocabulary such as *xrisimopió* ‘to use’, *praymatopió* ‘to realize’. It is worth noting that the majority of the verbs mentioned above are loan translations of English or French suffixed verbs.

Furthermore, the combination of quantitative evidence with qualitative observations (e.g. semantic, syntactic or other properties of verb-forming elements) seems to explain the productivity rankings of the items studied, an assumption also found in the literature (see, for example, Plag 1999). The example of *-pió*, *-évo* and *-áro* is characteristic: although *-pió* is used with only three meanings (instead of seven for *-évo* and *-áro*), it appears that its fewer phonological and morphological constraints, in comparison with *-évo* and *-áro* (see section 2 and Efthymiou et al. 2012), balance out its smaller number of meanings so that it shows similar productivity scores with them.

Finally, we believe that the findings concerning the productivity of *-pió* may offer evidence about its morphological status. In particular, the relatively high productivity of *-pió* could be considered as supporting the view that it has become a suffix in Greek. This suggestion could form a research hypothesis to be explored in a future research e.g. by measuring *-pió*'s productivity in relation to that of other affixoids.

THE FORM AND DISTRIBUTION OF SOME NEGLECTED MORPHOSYNTACTIC CATEGORIES IN THE HISTORY OF GREEK

ABSTRACT

In the present paper, we focus attention on the realization of the morphosyntactic Case category: Locative, and the Number (and Gender) category: Collective within the nominal and the pronominal paradigms and we examine their distinctive syntactic distribution in some special contexts and domains (e.g. Locative in connection with prepositional constructions, cf. Fykias 1997, 2003) in the course of the history of the Greek language, as well as some distinctive morphological and semantic properties (in the case of Collective). On the basis of widely accepted criteria, it is argued in favor of including these categories to the inventory of morphosyntactic categories of certain phases of Ancient and Modern Greek.

1. Introduction

From a purely typological point of view, *Case* distinctions such as *Locative* and *Comitative*, and *Number* distinctions like *Collective*, are far from unusual in a wide spectrum of languages. On the other hand, the conditions necessary for unanimously recognizing these morphosyntactic distinctions as a genuine part of the inventory of basic grammatical categories of a particular language seem to involve a) the *grammatical tradition* of the language involved (i.e. whether these distinctions have been established as grammatical categories in influential monumental accounts), and b) their *morphological representation*: one of the most prominent criteria seems to be whether the respective categories are realized – in a maximally distinctive fashion – (e.g. as specialized affixes) within the *nominal* paradigm.

In most standard analyses of Modern Greek, the categories mentioned above have not received special attention. One of the reasons for their exclusion from the set of basic grammatical categories is probably the fact that they are not overtly morphologically realized (as distinctive endings) within the nominal paradigm of Modern Greek (in the strict sense of the term), although there is ample evidence for the existence of those distinctions in Early Ancient Greek as well as in some Ancient Greek dialects (cf. Luraghi 2003, Seiler 1959), provided that we are ready to operate with standard heuristic procedures used by descriptive linguistics.

1.1 Locative and Instrumental in Archaic Greek

Within the framework of historical comparative Indo-European linguistics, the *communis opinio* purports that a limited number of forms attested in Classical Greek documents (as in 1 and 2 below) represent genuine instances of continuation of Indo-European Locative case.

- (1) Attic οἶκῳ (Dat.): οἶκοι (Loc. “at home”)

The two forms in (1a) are both morphologically and semantically clearly distinct. The locative formatives also occur mainly in association with some place names (e.g. Ἴσθμοι “on the Isthmos”).

- (2) Relics of earlier (paradigmatic) locative forms ending in -οι and -ει (ποῖ “where”, ἐκεῖ “there”), or respectively instrumental forms ending in -ω, -ᾱ, -ῃ (οὕτως “so”, λάθρα “in secret”, παντὶ “everywhere”). The form ending in -ω also occurs in adverbs that are canonically derived from

adjectives with the addition of -ς, compare κακῶς “badly” (cf. Wackernagel 2009: 371, Lorentzatos 1989, 34-39, Bartonek 2003: 151).

(3) This interpretation has been corroborated by the evidence adduced in connection with the discovery of Mycenaean Linear B tablets. In the Linear B documents, there were identified some dozens of lexical items with the ending -pi, that corresponds to the Homeric -φι. In the Mycenaean, however, this ending has a far more unambiguous function than -φι in Homer. It occurs only as plural ending and has an instrumental meaning. (vs. ἰφι “with force”)

(4) It has been standardly assumed that the case system in Mycenaean Greek consisted of 6 paradigmatic cases (Nom., Gen., Dat.-Loc., Acc., Voc., Instr.-Abl.). This pertains to masculine and feminine nouns in singular (cf. Bartoněk 2003: 160f). Syncretism of dative, locative and instrumental in Ancient Greek is clearly visible from morphology: the endings of the dative case in the various inflectional classes correspond to different endings of all three cases in the other Indo-European languages. The three cases did not merge at the same time: the earliest Greek texts, the Mycenaean tablets (about 1150 BCE), provide evidence for a stage at which the dative and the locative had already merged, but the instrumental was still distinct. (Bartonek 2003: 161-2, Hajnal 2006: 58-62). Later in the history of Greek (i.e. in the historical periods of Classical Greek and Hellenistic Greek) we could claim that there no forms of locative and instrumental attested. But at some point in the stage of Modern Greek we can show that there is a revival of the locative along with some cases.

A key to understanding this development is capturing some parallel developments in the grammatical system which led to a dramatic reorganization in the domain of pronominals. A grammatical phenomenon that has repeatedly been observed in the history of a great number of languages is the remodeling of the *nominal* system under the influence of the *pronominal* system and vice versa. This diachronic process has been documented in the history of many Indo-European languages, among which Greek takes a prominent position, both because of its long history and its documentation (at least as far as some important periods are concerned). The *morphological* dimension of this issue has received much attention in historical and theoretical linguistic studies. The evolution of both nominal and pronominal endings and the development of a separate set of clitic pronouns with distinctive properties belong to the well studied aspects of this issue (Dressler 1966, Seiler 1958). Dressler 1966: 39f offers a diagram outlining the reshaping of the system of personal pronouns of Greek in three successive periods.

(5) distinction full noun-accented pronoun- clitic pronoun

Classical Greek

1P.		2. P.		3. P.	
stressed	unstressed	stressed	unstressed	stressed	unstressed

εμείς--	εσείς --	αυτοί, -ά, -ές,	--
εμάς μας	εσάς σας	αυτών	τους
		αυτούς, -ά, -ές	τους, τα, τις/τες

1.2 The case distinctions of Modern Greek

In this paper, we will set out to pinpoint at some rather neglected aspects of the *purely syntactic* behaviour of tonic and *clitic* pronouns. Focussing on their case behaviour in connection with prepositions and adverbs, we compare the system of cases of Modern Greek (MG) with the case system of Ancient Greek (Classical and Hellenistic). Our working hypothesis is that the case system of clitic pronouns began to develop independently from the case system of lexical nouns and tonic pronouns at some very crucial points at some point after the first centuries A.D. One of the crucial parameters seems to involve the distinction: *structural* vs. *oblique* case (stated in moderately descriptive terms).

In Fykias 1995, 1997, there was presented some evidence supporting the existence of *Locative* and *Comitative* as independent abstract cases of MG in the context of complex PPs with locative or comitative meaning. Those cases are not commonly assumed to constitute a natural part of the case system of MG, partly because they are difficult to detect, since they are not canonically realized as morphological cases in nouns and in tonic pronouns. Their distribution is strictly limited to *clitic pronouns* in morphological *Genitive* in the aforementioned contexts. Nevertheless, specific semantic and distributional properties (see 6-9 below) clearly distinguish the cases instantiated in clitics in these special contexts (e.g. πάνω του, μαζί του) from the homonymous *Possessive Genitive* (e.g. το βιβλίο του).

- | | |
|---------------------------------|---|
| (6) a. πάνω τους | upon them |
| b. μαζί τους | together with them |
| c. εναντίον τους | against them |
| (7) a. * πάνω των σπιτιών | upon the houses GEN |
| b. * μαζί των παιδιών | together the children GEN |
| c. εναντίον των παιδιών | against the children GEN |
| (8) a. * πάνω τους των σπιτιών | upon them GEN the houses GEN |
| b. * μαζί τους των παιδιών | together them GEN the children GEN |
| c. (?)εναντίον τους των παιδιών | against them GEN the children GEN |
| d. * μαζί τους με τα παιδιά | together them GEN with the children ACC |
| e. εναντίον του του Γιάννη | against him GEN the Jannis GEN |
| (9) a. το σπίτι του Γιάννη | the house the Jannis GEN |
| b. το σπίτι του | the house him GEN |
| c. (?)το σπίτι του του Γιάννη | the house him GEN the Jannis GEN |

The special semantic or thematic properties of the prepositional constructions are the relevant factor, as far as case behavior or even the mere availability of the clitic are concerned. In Fykias 1997 it was shown, that there are crucial grammaticality differences distinguishing combinations involving instances of the same preposition depending on whether this lexical item has the genuine locative reading or not, as illustrated in sequences like the following in (10):

(10a) *αυτό είναι το άρθρο/θέμα που η καθηγήτρια έκανε μια διάλεξη πάνω του
This is the article/topic that the professor held a lecture on it

(10bi) * αυτό είναι το άρθρο/ βιβλίο που η Μαρία έγραψε μια κριτική πάνω του
this is the article/ book that the Maria wrote a review on it
(theme reading)

(10bii) αυτό είναι το βιβλίο που πάνω του η Μαρία έγραψε μια κριτική/σημείωση
this is the book that the Maria wrote a review/note on it
(locative reading)

The *πάνω* + *Clitic_{gen}* combination is possible only under a strict locative reading of *πάνω* (7bii). There seems to be a close connection between the presence of what can be interpreted as a genuine locative feature in *πάνω*, and the possibility to obtain the sequence *πάνω* + *Clitic_{gen}*. This fact could not be explained, if a general nominal genitive feature were responsible for the case of the clitic. The hypothesis, that the locative nature of the construction is the decisive factor, receives additional support, if we apply standard substitution tests such as the Question-Answer test by employing the specifically locative *πού* - *wh-question*, as in (11).

(11) πού πάνω έγραψε η Μαρία μια κριτική;
πάνω στο βιβλίο (only locative reading possible)

πάνω σε τί έγραψε η Μαρία μια κριτική;
πάνω στο βιβλίο (both readings are possible)

As soon as a locative interpretation is secured, the P + Clitic combination becomes possible. Under consideration of all those facts, one can arrive at a general comprehensive typology of MG prepositions and preposition-like elements which can be subsumed under (9):

(12) General typology of MG Prepositions

Type I Prepositions are prepositions co-occurring either with a full ‘nominal phrase’ or with a “tonic pronoun” realized as morphological accusative but not with clitics. We can divide Type I Prepositions into the following subtypes:

Type Ia: σε (in, at, to), από (from), με (with), για (for)

Type Ib: (privative) χωρίς (without), δίχως (without), έως / ως (up to), μέχρι (up to), ίσαμε (up to), (concessive) παρά (despite, inspite of), κατά (according to)

Type Ic: (temporal) μετά (after), πριν (before), επί (during), κατά (during), κατά (at about)

Type II Prepositions are prepositions co-occurring either with a Prepositional Phrase headed by some Type Ia prepositions (like σε, από and με), which take a full nominal phrase or a tonic pronoun in morphological Accusative as a complement, or with a *Clitic Pronoun* morphologically realized as Genitive (e.g. του, της in a combination like μαζί του (with him or accompanying him)). This *prima facie* exotic alternation is their trade mark, as it were.

Type II a. Locative: (ε)πάνω (upon, on), κάτω (under), μπροστά /εμπρός (in front of), πίσω (behind), μέσα (in, inside), έξω (outside, beyond), ανάμεσα (between), δίπλα (beside), πλάι κοντά (near), μακριά (far away from)

Type II b.

Comitative: μαζί (together with)

Type II c. or rather Type IV

Temporal: (+ από απο) ύστερα, έπειτα, μετά (after), πριν (before)

Manner: σύμφωνα με, ανάλογα με

Type III Prepositions co-occurring either with a full nominal phrase realized as morphological Genitive or a Clitic pronoun also realized as Genitive (e.g. εναντίον του Πέτρου (against Petros-GEN) and also εναντίον του). Apart from εναντίον, ενώπιον, there are less clear cases like κατά (against),

υπέρ (in favour of), μεταξύ (among, between), εξαιτίας (because of), εις βάρος, κατά τη διάρκεια (during).

In Fykias 2003: 656, there was adduced distributional evidence for an additional abstract case, namely *Oblique Accusative* in the context of prepositions assigning morphological Accusative like σε, από but also χωρίς. The distribution of Oblique Accusative is restricted to *tonic pronouns* and lexical nouns.

So the essentials of the analysis proposed can be subsumed as (13a) and (13b):

Assumptions:

(13a) Clitic pronouns cannot manifest all abstract cases available in Modern Greek.

(13b) Lexical nouns and tonic pronouns cannot manifest all abstract cases available in Modern Greek.

Table (14) illustrates a *tentative* sketch of the system of abstract cases in MG as well as their distribution depending on the exact nature of the nominal categories that they are associated with. It is conceived of as an answer to the question of whether the abstract cases under consideration are available or not.

(14)

	Lexical nouns	& tonic pronouns	Clitic pronouns
Structural accusative:	yes		yes
<u>Oblique accusative:</u>	yes		no
Dative:	yes		yes
Possessive:	yes		yes
<u>Partitive:</u>	no		yes
<u>Locative:</u>	no		yes
<u>Comitative:</u>	no		yes

The context of Oblique Accusative

(15)a. πήγα με τον Γιάννη

(15)b. *πήγα με τον

(16)a. πήγα χωρίς τον Γιάννη

(16)b. *πήγα χωρίς τον

(17) a. μετά (από) τον Γιάννη

(17) b. *μετά τον

(17)c. μετά *(από) αυτόν

There has been no convincing explanation of the fact that the configuration: (*morphological*) *Accusative* “*assigning*” *preposition* + *accusative clitic pronoun* is simply not available in MG. The analyses suggested so far fail to account for the fact that the same generalization applies to type Ib and type Ic prepositions as well (see 12). A **clitic-clitic* filter account cannot be the right answer for configurations involving stressed type Ib prepositions like μέχρι, χωρίς, (the trisyllabic!) ίσαμε, έως. On the other hand, there is ample evidence that the **clitic-clitic* filter solution is a far too powerful explanation, as the acceptability of examples like (18) below, involving type II and type III prepositions clearly suggests.

(18) θέλετε τον καφέ μέ ή χωρίς ζάχαρη;
do you like the coffee with or without sugar?

2. Locating diachronic changes and variation

As mentioned above, reliable morphological evidence shows that the case system of clitic pronouns has developed independently from the case system of lexical nouns. The crucial parameter seems to

involve the distinction *structural* vs. *oblique case*, and this distinction enables us to capture significant descriptive generalizations on structural and oblique abstract cases both in the synchrony and in the diachrony of Greek.

Examples with locative quasi prepositional items of New Testament (NT) Greek like ἐπάνω, “upon”, ὀπίσω “behind” and ἐνώπιον “in the sight of” that are still present in MG (in the case of ἐνώπιον in a more formal/learned register of MG) and illustrate that, in NT Greek, there was *no asymmetry* between clitic pronouns on the one hand and lexical nouns and tonic pronouns on the other, as far as case distribution is concerned. Remarkably, we are in the fortunate position to compare the behaviour of the same lexical items in the course of their history and development. Nevertheless, there is a methodological limitation in connection with the second part of the syntagma *preposition + pronominal*: Only in the case of the 1st person singular we can clearly distinguish between tonic pronouns and clitics (in particular ἐμοῦ vs. μου, ἐμοί vs. μοι, and ἐμέ vs. με), as far as AG pronominal data are involved, cf. the following examples (19)

(19a) ὀπίσω + full lexical noun in morphological genitive

(i) 1Ti 5:15 ἤδη γάρ τινες ἐξετράπησαν ὀπίσω τοῦ Σατανᾶ.

“For some (widows) have already turned *away to follow Satan*. (lit. behind Satan)”

(ii) 2Pe 2:10 μάλιστα δὲ τοὺς ὀπίσω σαρκὸς ἐν ἐπιθυμίᾳ μiasμοῦ πορευομένους

“especially *those who satisfy their flesh* (lit. the ones behind the flesh) by indulging in its passions”

(19b) ὀπίσω + tonic pronoun in morphological genitive

(19c) ὀπίσω + clitic pronoun in morphological genitive

(i) Mat 3:11 ὁ δὲ ὀπίσω μου ἐρχόμενος ἰσχυρότερός μου ἐστίν,

“but the one who is coming *after me* is stronger than I am,”

(ii) Mat 4:19 Δεῦτε ὀπίσω μου, καὶ ποιήσω ὑμᾶς ἁλεῖς ἀνθρώπων.

“Come *after Me*, and I will make you fishers of people.”

(20) a. ἐπάνω + full lexical noun in morphological genitive

Mat 5:14 οὐ δύναται πόλις κρυβῆναι ἐπάνω ὄρους κειμένη

“A city located *on a hill* can't be hidden”

b. ἐπάνω + tonic pronoun in morphological genitive

Mat 21:7 καὶ ἐπέθηκαν ἐπ' αὐτῶν τὰ ἱμάτια, καὶ ἐπεκάθισεν ἐπάνω αὐτῶν.

“and did put on them their garments, and set *him* upon them”

Mat 23:18 ὃς δ' ἂν ὁμώσει ἐν τῷ δώρῳ τῷ ἐπάνω αὐτοῦ ὀφείλει:

but whoever may swear by the gift that is upon it--is debtor!

c. ἐπάνω+ clitic pronoun in morphological genitive

LXX 2Sa 1:9 Στήθι δὴ ἐπάνω μου καὶ θανάτωσόν με.

“Stand, I pray thee, *beside me*, and slay me”

In sharp contrast to the MG-pattern in (15-17 above) there is a remarkable parallelism between (21) to the pattern possessive constructions canonically instantiate. Finally, there are prepositions like ἐνώπιον or ἐναντίον which have preserved the same pattern (but at least in the case of ἐναντίον they have changed their meaning) to our times and which essentially behave like a lexical noun cooccurring with possessive genitive.

(21)

Luc 1:15. ἔσται γὰρ μέγας ἐνώπιον Κυρίου,

For he shall be great in the sight of the Lord

Luc 1:17 καὶ αὐτὸς προελεύσεται ἐνώπιον αὐτοῦ ἐν πνεύματι καὶ δυνάμει

And he shall go before him in the spirit and power

The following sequences in Mat 3:14 and Luc 1:43 are especially interesting, since they represent some of the very rare known cases of the combination P + accusative Clitic in the history of Greek.

(22)

Mat 3:14 σὺ ἔρχῃ πρὸς με;
comest thou to me (Clitic_{ACC})?

Luc 1:34 εἶπεν δὲ Μαριάμ πρὸς τὸν ἄγγελον
Then said Mary unto the angel

Luc 1.43 ἵνα ἔλθῃ ἡ μήτηρ τοῦ κυρίου μου πρὸς ἐμέ;
that the mother of my Lord should come to me(tonic pronoun_{ACC})?

3. Collective as a morphological and syntactic category of Ancient and Modern Greek

3.1 Ancient Greek

Every student of Ancient Greek is familiar with a rather exotic phenomenon of the Attic dialect, the so-called τὰ ζῷα τρέχει-rule ('the animals are running'), which is very often analyzed in standard grammars as in Smyth 1956: "A neuter plural subject is regarded as a collective and has its verb in the singular: καλὰ ἦν τὰ σφάγια 'the sacrifices were propitious' Xen. A. 4.3.19." with the additional remark: "The neuter plural seems to have been originally in part identical in form with the feminine singular in ā, and to have had a collective meaning". This agreement pattern: subject (neuter plural) + verb (third person singular), was eventually lost. In most of the dialects we have no traces of this pattern. It is preserved most faithfully in Attic Greek, though in the Attic based Koine, it begins to decline, with the result that in the NT and early Christian literature there is considerable variation in its use. Thanks to the progress of Indo-European comparative linguistics it soon became evident, that this usage is not a Greek innovation, since it systematically occurs in Vedic, Avestan and Hittite as well. It is inherited and it reflects the fact that the plural of the neuter does not have the same meaning as the plural of masculine and feminine. Especially important, is Johannes Schmidt's (1889) thesis in his treatise on the plural forms of neuters in Indo-European, regarding the primary relatedness of the neuter plural with certain singular collectives of feminine gender. Wackernagel also adduces a typological argument from languages which make a formal distinction between words for animate and inanimate objects (in Mexicano, for example), only the animate nouns have a plural. (cf. Wackernagel 2009: 136ff). Apart from this most salient rather syntactic feature¹ of collective nouns, it can be shown that they have further traits that are characteristic of this kind of constructions. Among the collective items, we often meet nouns with two plurals like in Hittite (*alpas* 'cloud' *alpes* 'clouds' *alpa* 'cloud-mass') and even in Latin (*locus* 'place' *loci* 'places' *loca* 'places' (Latin / Umbrian Latin *uir* 'man' Latin *uiri* 'men' Umbrian *uiri* 'people')(cf. Clackson 2007 :102). This fact can be illustrated in connection with Greek by means of the following examples:

Nouns with two plurals (cf. Meier-Brügger 2006:116).

Nominative singular	Nominative plural	Collective plural
ἀστήρ 'star'	ἀστέρες	ἄστρα
δεσμός	δεσμοί	δεσμά
ἰός	ιοί	ἰά
κέλευθος	κέλευθοι	κέλευθα
κύκλος 'wheel, circle'	κύκλοι 'circles'	κύκλα 'set of wheels' (of a chariot)
μηρός 'thigh'	μηροί 'thigh-pieces'	μῆρα 'agglomeration of thigh-meat'
οἶκος	οἴκοι	οἴκα-δε
σῖτος		σῖτα
Τάρταρος		Τάρταρα
myc. ka-po=karpós		myc. ka-pa=kárpa
myc. o-no		myc. o-na

¹ Cf. Wackernagel 2009: 139: "The tendency to treat singular nouns with plural meaning as plurals, despite their form, and when, e.g., they are in subject position, to put their verb in the plural (even though this topic really belongs under grammatical agreement). In Greek there are examples already in Homer" and in other poets guided by a *constructio κατά σύνεσιν* principle. Some of the dialects attest in ordinary speech a regular preference for the usage, e.g. Cretan, πόλις, στρατός ('city', 'army') regularly taking a plural verb.

The interpretation of the significance of the original distribution is not always possible. But it appears that what we have called the *-h₂ plural* has more of a collective meaning, and the regular plural has a more distributive meaning; the contrast between these two formations is lexically restricted. Furthermore, it is not difficult to fit a distributive or collective meaning to a certain form according to context, particularly in the case of languages where we only have a restricted corpus (cf. Clackson 2007 :102)

3.2 Collectives in Modern Greek

Is there any justification for assuming collective as a morphosyntactic category: for Modern Greek? If we are ready to categorize as collective constructions that do not fulfill all the criteria but most of the criteria, then we are faced with an interesting situation in Modern Greek. The criterion that is definitely not met is the agreement pattern: subject (preferably neuter plural) + verb (third person singular). For some potential candidates see 22-25 below:

(23)

Nouns occurring only in plural or mainly in a plural form (cf. Triantafyllidis 1991: 224). A great number of common nouns with intrinsically collective meaning: βαφτίσια (baptism ceremony), γένια (beard), γεράματα (old age), εννιάημερα (novena, memorial service held 9 days after a person's death), κάλαντα ((Christmas) carols), λύτρα (ransom), μεσάνυχτα (midnight), μετρητά (cash), παλαμάκια (clapping, applause), παρακάλια (entreaties), παρασκήνια (wings backstage), πεθερικά (in-laws), πρόθυρα (threshold, verge), προικιά (dowry), ρέστα (change), τάρταρα, τρεχάματα (running about, hectic time), χαιρετίσματα (greetings), χαράματα (dawn, daybreak), χειροκροτήματα (clapping, applause) etc.

(24) Words that also belong to this category are a) collective mass nouns par excellence like: ασημικά (silverware), ζυμαρικά (pastry), όσπρια (legumes, pulses), πουλερικά (poultry), χορταρικά (vegetables); b) Words that denote objects which are dual or complex by nature (τα γυαλιά, τα κιάλια) or dvandva compounds like: αμπελοχώραφα (fields and vineyards), γιδοπρόβατα (sheep and goats) , γυναικόπαιδα (women and children) etc.; c) Some nominalized adjectives like: ψιλά (small change), ρηχά (shallows), τα οικονομικά (the economic financial situation), and items meaning denoting reward for some work or task: κόμιστρα (fare, transportation charges), ασφάλιστρα (insurance rate); d) Words denoting a language, like: αρβανίτικα, ελληνικά, κινέζικα etc., cf. Triantafyllidis 1991: 224-5.

(25) Triantafyllidis 1991: 225: a) Names of holidays: Χριστούγεννα,(Christmas), Κούλουμα (Shrove Day feast); b) toponyms²: Σέρρες, Σπέτσες, Ουράλια etc; The name of some cities or towns that is usually a singular may also occur in a plural form: Αθήνα - Αθήνες, Θήβα - Θήβες³.

(26) Nouns with double declension/two plurals:

a) With change of gender in plural: ο πλούτος-τα πλούτη (wealth), ο σανός — τα σανά (hay fodder), ο τάρταρος underworld — τα τάρταρα (the bowels of the earth). The noun νιότη has as plural the form τα νιάτα (that do not have a singular form).

b) With a double gender in plural (the two forms of plural sometimes differ in meaning, cf. Meier-Brügger 2006: 116 on Mycenaean *ka-pa*), namely a plural form in distributive function and a plural form (neuter) in collective function:

ο βάτος οι βάτοι — τα βάτα bramble

ο βράχος οι βράχοι — τα βράχια rock

ο δεσμός οι δεσμοί, bond and with an abstract meaning, δεσμοί φιλίας — τα δεσμά

ο γκρεμνος οι γκρεμνοί — τα γκρεμνά precipice (Triantafyllidis 1991: 257)

ο καπνός οι καπνοί (smoke) — τα καπνά, tobacco

ο λαιμός οι λαιμοί — τα λαιμά for the surface of the neck or the throat and usually for a neck/throat sickness

ο λόγος οι λόγοι — τα λόγια (genitive των λόγων)

ο ναύλος οι ναύλοι fare) — τα ναύλα expenses

² Symeonides 1992: 59 remarks in connection with toponyms based on Greek loans in the language of Albanian speaking Greeks who allot the diminutive suffix -za a new collective meaning, e.g. Βάρκι-ζα, Βελανιδέ-ζα.

³ Toponyms in Pl. like Θήβες occur (mainly) in oblique cases: των Πατρών, των Αθηνών, *οι Αθήνες, *οι Πάτρεις (older forms: Αθήναι, Πάτραι).

The difference reflects a difference in point of view: the singular stresses the nonpersonal collectivity of the group, and the plural stresses the personal individuality within the group.
As a last collective subcategory, it is interesting to note that in MG collective in connection with pronominal categories is also expressed as neuter plural.

- (27) Τα θέλω όλα
I want all things
I want everything

4. Final remarks

Wackernagel (2009: 138) remarks in connection with collective on the possibility for several morphosyntactic constructions and phenomena to recur in the course of the history of a language. “In a sense, the Romance languages regressed to an ancient state of affairs when feminine singulars evolved out of Latin neuter plurals, as in *la voile* ('sail') from Lat. *uela*, or *la joie* ('joy') from Lat. *gaudia*”. In the same vein, Kurylowicz (1964, preface) claims “Such shifts as as iterative>durative ...adverb> ‘concrete case’>grammatical case, collective>plural ... recur constantly and independently in all languages. They represent diachronic universals and must be somehow enrooted, directly or indirectly, in the elementary speech situation.” We are convinced that this possibility of regressing can be utilized in connection with Cases. We believe to have shown that Locative Case in the course of the history of Greek followed a life cycle of a kind, as suggested by Blake 2004 :161f., who notes that “there are some languages, including the Indo-Iranian branch of Indo-European, where the development of ‘new’ case markers is attested”. By about 1150 BCE the dative and the locative had already merged, but the instrumental was still distinct. (Bartonek 2003: 161-2, Hajnal 2006: 58-62). In the historical periods of Classical Greek and Hellenistic Greek there no forms of locative and instrumental attested. But at some point in the stage of MG, there was a revival of the locative in connection with clitic pronouns in the restricted domain of locative prepositional expressions.

COMPREHENSION IN GREEK-SPEAKING AGRAMMATISM: A CASE STUDY

Valantis Fyndanis

University of Athens &
Technological Educational Institute
of Patras, Greece

valantis.fyndanis@gmail.com

ABSTRACT

This study reports data of a Greek-speaking agrammatic patient on four constrained tasks tapping comprehension of semantically reversible active and passive sentences, subject-verb Agreement, Tense, Aspect, and CP. The results, discussed in light of recent hypotheses, indicate that in agrammatic comprehension—and at least for some patients—canonical and non-canonical sentences may not dissociate and, further, functional categories associated with the verb morphology may be compromised in the face of well-preserved categories located higher in the syntactic hierarchy.

Keywords: agrammatism, comprehension, grammaticality judgment, Agreement, Tense, Aspect, Complementizer Phrase.

1. Introduction

It is well established that agrammatic patients have often difficulties comprehending semantically reversible sentences involving movement of a Determiner Phrase (DP) from its θ -position to a higher one, such as passive sentences, object relative sentences, and object cleft sentences (e.g., Caramazza & Zurif, 1976). Comprehension of reversible sentences requires successful processing of syntactic information, which is assumed to be impaired in agrammatism (e.g., Avrutin, 2006). In contrast, agrammatics are able to successfully comprehend irreversible sentences based on semantic cues. Several accounts have been proposed to capture the syntactic problems agrammatic patients face in the comprehension of reversible sentences. According to the influential Trace Deletion Hypothesis (TDH) (Grodzinsky, 1995), traces that DP movement leaves behind are deleted from the sentence representations of agrammatics, a process which results in their inability to use syntax in order to assign θ -roles to the moved arguments. In such cases, they resort to a cognitive strategy assigning the agent role to the linearly first argument of the sentence. Consequently, in passive sentences with an overt by-phrase, representations with two agents are built up, leading agrammatics to perform at chance on this sentence type.

In line with Caramazza and Zurif's (1976) findings, several researchers report that, unlike movement-derived reversible sentences, "simple" canonical active sentences do not cause comprehension difficulties to agrammatics (for a review, see Grodzinsky, Piñango, Zurif, & Drai, 1999). Recent studies, however, indicate that comprehension of simple active sentences can also be impaired in agrammatism. For instance, structures used to test functional categories such as subject-verb Agreement, Tense, or CP can be affected (e.g., Dickey, Milman, & Thompson, 2008; Stavrakaki & Kouvava, 2003).

A number of accounts have been argued to capture agrammatic comprehension data related to functional categories, although some of them were originally proposed to account for production data. Here I will focus on four of them: (a) Tree Pruning Hypothesis (TPH) (e.g., Friedmann, 2006), (b) Tense Underspecification Hypothesis (TUH) (Wenzlaff & Clahsen, 2004, 2005), (c) Interpretable Features' Impairment Hypothesis (IFIH) (Fyndanis, Varlokosta, & Tsapkini, 2010, 2012; Nanousi, Masterson, Druks, & Atkinson, 2006; Varlokosta, Valeonti, Kakavoulia, Lazaridou, Economou, & Protopapas, 2006), and (d) Distributed Morphology Account (DMA) (Dickey, Milman, & Thompson, 2008; Thompson, Fix, & Gitelman, 2002).

According to the TPH (e.g., Friedmann, 2006), agrammatism arises from a “pruning” of the syntactic tree, usually at the Tense node; categories hosted above the pruning point (e.g., CP) are inaccessible, whereas those located below (e.g., subject-verb Agreement, at least in Hebrew) are intact.

Within the minimalist spirit (e.g., Chomsky, 1995), the TUH (Wenzlaff & Clahsen, 2004, 2005) posits that the selective difficulties of agrammatic speakers with Tense are due to the underspecification of this category within the T/INFL node, in the face of the other well-preserved features hosted within the same node (e.g., Agreement, Mood, in German). This hypothesis, therefore, attributes the Tense deficits in agrammatic comprehension (and production) not to the impaired projection of the syntactic hierarchy, but to morphological/morphosyntactic processes.

Exploiting the minimalist notion of Logical Form (LF)-Interpretability (e.g., Chomsky, 1995, 2001), the IFIH (Fyndanis et al., 2010, 2012; Nanousi et al., 2006; Varlokosta et al., 2006) suggests that, in agrammatism, categories with LF-interpretable features (e.g., Tense, Aspect) are expected to be significantly more impaired than categories with LF-uninterpretable features (e.g., Agreement). Fyndanis et al. (2010, 2012) argue that, given the processing limitations of agrammatics, the dissociation between “interpretable” and “uninterpretable categories” is due to their differential processing demands. “Interpretable categories” are more demanding in terms of processing resources compared to “uninterpretable categories”, since the former require processing and integration of grammatical and extralinguistic/conceptual information; in contrast, “uninterpretable categories” involve processing of grammatical information only.

The DMA (Dickey et al., 2008; Thompson et al., 2002) was based on the patterns of performance Dickey et al.’s (2008) and Thompson et al.’s (2002) patients exhibited, which were consistent with the assumption of Distributed Morphology (Halle & Marantz, 1993; Harley & Noyer, 1999) that the syntactic component operates separately from the morphological component, but that the latter takes the outputs of the former (phrase structures and feature bundles) as input for its computations. In particular, in a study focusing on comprehension, Dickey et al. (2008) reported significantly better performance of English-speaking agrammatic individuals on judgments of CP-related structures, rather than of IP-related ones. According to the authors, the selective comprehension deficit affecting verbal morphology categories in the face of well-preserved higher projections is in line with the above-mentioned assumption of Distributed Morphology. It is suggested, thus, that probably what is genuinely affected in agrammatic individuals is not syntax, but morphological insertion processes (Dickey et al., 2008; see also Thompson et al., 2002).

Only a few published studies have investigated the comprehension of functional categories in Greek-speaking agrammatic aphasia, while only Stavrakaki and Kouvava (2003) and Alexiadou and Stavrakaki (2006) have examined a wide range of functional categories. I will only focus on the comprehension data of these studies, which are of interest here.

Stavrakaki and Kouvava (2003) tested the abilities of two Greek-speaking agrammatic patients to comprehend subject-verb Agreement, Tense, Negation, Mood, and CP using a grammaticality judgment task and a preference test between grammatical and ungrammatical sentences. Regarding CP, they examined both the specifier and head positions. Furthermore, regarding Negation, they tested the comprehension of both negative particles in Greek, *δέν* and *μίν*, which are used in the indicative and subjunctive Mood, respectively. In the grammaticality judgment task, Stavrakaki and Kouvava’s first patient, SC, performed above chance¹ on Agreement, Tense, Negation in indicative Mood, and Spec, CP², and at chance on Mood, Negation in subjunctive Mood and C°. VF, their second patient, performed above chance on all the conditions of the grammaticality judgment task.³ According to the

¹ The characterizations of the performance of Stavrakaki and Kouvava’s (2003) patients in terms of chance performance were not provided by the authors, but they are based on statistical comparisons (by Binomial test) made in the present study.

² Spec, CP was assessed through items testing operator movement in embedded questions and through wh-NP constructions. SC performed above chance on the former and at chance on the latter. Wh-NP constructions, however, also involve a “discourse component” (they are *Discourse-linked*, in terms of Avrutin (2000)), which has been argued to place an extra burden on speakers’ processing system (op. cit.); therefore, the testing of Spec, CP through wh-NP constructions is confounded with this component. In fact, based on these items, SC performed at chance on Spec, CP. Hence, Stavrakaki and Kouvava’s patients’ abilities to handle the Spec, CP position in comprehension can be best assessed based on their performance on the condition testing operator movement in embedded questions.

³ In the grammaticality judgment task, each condition included 20-24 items. On the other hand, the preference test included only 10-12 items per condition, which, in some cases, does not allow to draw firm conclusions about the ability of Stavrakaki and Kouvava’s participants to comprehend the functional categories under consideration. For example, SC performed 8/10 correct on three conditions, namely Neg-*δέν*, Neg-*μίν*, and Mood, which, by a Binomial test, corresponds to chance performance (two sided $p = .109$). It is doubtful, however, if indeed this patient’s ability to comprehend these categories is impaired. In fact, his performance on the Neg-*δέν* condition of

authors, these results indicate that, despite the individual variation observed, both patients show a high degree of grammaticality sensitivity. Strong evidence for this is provided by their high performance on structures involving functional categories located high in the syntactic tree (i.e., embedded object wh-questions).

Alexiadou and Stavrakaki (2006) tested the ability of a Greek-English bilingual individual with Broca's aphasia and mild agrammatism, KS, to judge adverb placement in sentences through a contrastive grammaticality judgment task.⁴ This task included adverbs associated with different functional (and lexical) projections: CP, MoodP, AspectP, NegP, and VP. In Greek, KS's performance was quite high on all types of adverbs. Although the higher the functional projection with which a given adverb was associated, the lower KS's performance was, no significant dissociations were observed between the different adverb types/functional projections. KS's results, therefore, indicate increased grammaticality sensitivity for all the functional projections tested.

Against this background, the goal of this study is two-fold: (a) to contribute new comprehension data aiming at the better understanding of the way Greek-speaking agrammatic aphasia manifests itself in this modality; (b) to relate the data reported here to the comprehension data provided by Stavrakaki and Kouvava (2003), and Alexiadou and Stavrakaki (2006), and discuss them all in light of the above-mentioned theories of agrammatic comprehension. In particular, this study investigates the ability of a Greek-speaking agrammatic patient to comprehend a wide array of syntactic structures and functional categories: reversible canonical and non-canonical sentences, wh-questions/CP, Tense, Aspect, and subject-verb Agreement.

2. Verbal morphology and clause structure in Greek

Greek is a null subject language with rich morphology and relatively free word order (Holton, Mackridge, & Philippaki-Warbuton, 1997). The canonical order in Greek is VSO (e.g., Roussou & Tsimpli, 2006). A number of grammatical (functional) categories are instantiated in the Greek verb morphology, such as Agreement, Tense, Aspect, Voice, and Mood (Holton et al., 1997). Greek does not have infinitives and the only non-finite forms are the gerund and the non-finite form that is used to compose the perfect tenses.

The distinction between imperfective and perfective Aspect shows up in the past tense, in the future tense, and in the *na*-constructions (subjunctive). No aspectual distinction is made in the present tense, as it always uses the imperfective stem.

According to Tsimpli (1990), the likely clause structure for Greek with respect to CP, Agreement Phrase (AgrP), Tense Phrase (TP), and Aspect Phrase (AspectP) is (1) (but see Philippaki-Warbuton, 1998, for a different analysis⁵):

- (1) **CP > (MoodP) > NegP > TP > AgrP > AspectP > VP**

Given the syntactic hierarchy above, the predictions of the five theories discussed in the Introduction for Greek-speaking agrammatic aphasia are summarized in Table 1.

3. Methods

3.1 Participants

A Greek-speaking agrammatic patient, GL, and an age-, gender-, and education-matched control participant, SA, were tested. Details about the diagnosis of agrammatism, demographic and lesion information, and language testing data are given in Fyndanis et al. (2010, 2012).

the grammaticality judgment task, which elicited a % rate similar to that elicited by the preference test (17/20, 85% correct vs. 8/10, 80% correct, respectively), is above chance (by Binomial test, two sided $p = .003$). For this reason, in the present study, only the results of the grammaticality judgment task are reported.

⁴ Alexiadou and Stavrakaki (2006) also examined the production modality (with a constituent ordering task), which, however, is not relevant to the present study.

⁵ For the different predictions the TPH (Friedmann, 2006) would make depending on which of the two alternative analyses is adopted, see Fyndanis (2009: 63-67). Crucially, irrespective of which analysis is adopted, the results of this study lead to the same conclusions with respect to the adequacy of the TPH to capture the agrammatic participant's pattern of performance.

3.2 Experimental investigations

Four tasks were developed overall: a sentence-picture matching task to test comprehension of canonical active and (non-canonical) passive sentences, a sentence-picture matching task to test comprehension of Tense, a sentence grammaticality judgment task to test judgment/comprehension of subject-verb Agreement, Tense, and Aspect, and a picture-pointing task to test comprehension of wh-questions, which involve the CP.

3.2.1 Sentence-picture matching task I: Aim/Design/Procedure

A sentence-picture matching task was developed to investigate whether GL has greater difficulty comprehending sentences with non-canonical argument order (object-subject), compared to sentences with canonical argument order (subject-object). The task included 18 reversible passive sentences and 18 reversible active sentences. The same, two-

TDH	reversible passives < reversible actives
TPH	CP, Tense < Agreement, Aspect
TUH	Tense < Agreement, Aspect
IFIH	Tense, Aspect, CP ⁶ < Agreement
DMA ⁷	Tense, Aspect, Agreement < CP

Table 1 Predictions of the five hypotheses discussed in Section 1 for comprehension in Greek agrammatism.

Figure 1 This set of pictures was accompanied by the sentences *To korítsi xastucízi to ayóri* ‘The girl is smacking the boy’ and *To korítsi xastucízete apó to ayóri* ‘The girl is being smacked by the boy’

place verbs were used in both sentence types. Each sentence was accompanied by four pictures including the target picture, a picture with role reversal, and participant and action foils. An example is given in Fig. 1. Participants were auditorily presented with the sentences and required to point to the picture that matched the sentence they heard. The task was administered in two sessions, with at least a five-day interval in between. The block with the actives was administered first (session 1), followed by the block with the passives (session 2). Training to the participants was provided at the beginning of each session. The control participant had ceiling performance on both actives and passives and, thus, his performance will be further ignored.

3.2.2 Sentence-picture matching task II: Aim/Design/Procedure

Another sentence-picture matching task was developed to test comprehension of Tense. This task included 18 active sentences with canonical argument order. Each sentence was accompanied by three randomly ordered black and white line drawings depicting three temporal versions (*past*, *present*,

⁶ Wh-questions, which are used to test CP here, are considered to carry uninterpretable features (Tsimpli & Stavrakaki, 1999: 51).

⁷ The DMA (Dickey et al., 2008; Thompson et al., 2002) would be consistent with impairment in categories associated with the verbal morphology in the face of well-preserved higher projections, such as CP. Other patterns, however, would not necessarily undermine the validity of the DMA. For instance, similar impairments in verbal morphology and CP could be attributed to deficits in both the syntactic and morphological components.

future) of a given event. Participants were asked to point to the drawing that matched the sentence they heard. An example of the past tense condition is given in Fig. 2. Seven sentences were in the past Tense, six in the present, and five in the future. The control participant made no errors and, thus, his performance will be further ignored.

3.2.3 Sentence grammaticality judgment task: Aim/Design/Procedure

The sentence grammaticality judgment task aimed at exploring GL's ability to judge/comprehend subject-verb Agreement, Tense, and Aspect. This task comprised 168 active sentences with canonical argument order, 56 per functional category, of which –in each condition– half were well-formed and half ill-formed. The vast majority of the sentences (150 overall, 50 in each condition) were irreversible. The same 56 verbs (two-place transitive, stressed on the penultimate syllable) were used in all three conditions. Participants were auditorily presented with the sentences, and asked to judge whether they sounded correct or not. The pairs of sentences in (2), (3), and (4) are examples of well-formed and ill-formed sentences in the Agreement, Tense, and Aspect conditions, respectively.

- (2) a. Esí akús musicí. *You_{sg} hear_{2nd.sg} music*. 'You listen to the music'
 *b. Esí épina bíra. *You_{sg} drank_{1st.imperf} beer*. 'You was drinking beer'
- (3) a. Xθés esí éplases kuluráca. *Yesterday you_{sg} shaped_{2nd.sg} scones*.
 *b. Ávrio eyó épsisa brizóles. *Tomorrow I cooked_{1st.sg} steaks*.
- (4) a. Ávrio esí tha mirázis ta ðóra epí mía óra. *Tomorrow you_{sg} will give out_{2nd.sg.imperf} the gifts for an hour*.
 *b. Xθés aftí kúrðisan ta rolója epí dío leptá. *Yesterday they wound_{3rd.pl.perf} the clocks for two minutes*.

In the Agreement condition, of the 28 ill-formed sentences, half violated number Agreement and half violated

person Agreement. All the Agreement values were included as targets (either realized or not) and were relatively evenly distributed between the well-formed and ill-formed sentences.

In the Tense condition, the well-formed sentences were crossed with all target Tense values, while the ill-formed

sentences were only crossed with past and future. The reason for the exclusion of the present Tense from the ill-formed sentences is that sentences with verbs in past or future and with adverbials prototypically associated with present (e.g., *tóra* 'now') can be considered acceptable. Therefore, in order to include the same number of well-formed and ill-formed sentences, as well as the same number of sentences for each target Tense, I used only well-formed sentences for the present Tense and counterbalanced through the ill-formed sentences, which all had past or future as their target Tense and, further, utilized the past vs. future contrast between adverbials and verbs.

Aspect was tested only within indicative (unmarked Mood). Of the 56 sentences in this condition, 28 had the perfective as their target Aspect and 28 the imperfective. The subsets above were crossed yielding a relatively even distribution of the relevant variables (\pm well-formedness, \pm perfectivity) and presented an even distribution between past and future. The present was not included as it does not mark morphologically the distinction between the perfective

Figure 2 This set of pictures was accompanied by the sentence *To ayóri évrekse to korítsi* 'The boy dumped water on the girl'

Figure 3 For this picture the following questions were asked (in Greek): *Who is the monkey chasing? Who is the dog chasing? Who is chasing the monkey? Who is the elephant chasing? Who is chasing the cat?*

and imperfective Aspect.

The grammaticality judgment task was divided into four blocks of 42 items. Each block included 14 items testing Agreement, 14 testing Tense, and 14 testing Aspect. In each block the same verb never appeared more than once. The three conditions were mixed and randomized, and the resultant order of items was kept constant for both participants.

More than three consecutive items of the same condition and more than four consecutive well-formed or ill-formed sentences never occurred. The task was administered within four sessions, with at least a five-day interval in between. No session lasted more than 45'.

3.2.4 Picture-pointing task: Aim/Design/Procedure

A picture-pointing task was developed to test comprehension of wh-questions, which involve the CP (at least for object questions). The design and results of this experiment are reported by Fyndanis et al. (2010). However, for the reader's convenience I briefly provide the relevant details. In this task, the participants were presented with four black and white line drawings. Each line drawing depicted a "reversible" action performed by four animate entities (people or animals) (see Fig. 3). Each of the animate entities constituted either one of the agents or one of the themes of the depicted proposition, or even both of them. For each line drawing, five (subject and object) argument questions were read aloud by the experimenter and the participants were asked to point to the person or animal representing the answer to each question. Ten subject and 10 object questions were included overall. This task was administered in two sessions, with a 15-day-interval in between. In each session the participants were presented with two drawings and 10 wh-questions. GL's control participant performed at ceiling, so his performance will be further ignored.

4. Results

4.1 Results from the sentence-picture matching task I

As shown in Table 2, GL performed high on both active and passive sentences (94% correct on both). Certainly, his performance was above chance on the two sentence types. (Given that each trial included four pictures, the chance level for this task is 25%.)

	actives	passives	Total	actives vs. passives	actives vs. chance level (25%)	passives vs. chance level (25%)
GL	17/18 (94%)	17/18 (94%)	34/36 (94%)	$p = 1$	$p = .000$ above chance	$p = .000$ above chance

Subject questions	9/10 (90%)	ab. chance ($p = .000$)
Object questions	10/10 (100%)	ab. chance ($p = .000$)
Total	19/20 (95%)	ab. chance ($p = .000$)

Table 5 Raw and percent accuracy scores, and comparisons (by Binomial test, using R) for GL in the picture-pointing task

4.2 Results from the sentence-picture matching task II

GL's correct performance on the sentence-picture matching task II amounted to 56% (Table 3). The comparison (by Binomial test) between his raw data and the chance level for this task (33.3% given that each trial included three pictures) revealed that he had chance performance on the comprehension of Tense.

4.3 Results from the sentence grammaticality judgment task

The results from the grammaticality judgment task are presented in Table 4. Overall, GL performed 68% correct on this task. He performed significantly worse on all three categories than his control participant (by Fisher's exact test; Tense: $p = .008$, Agreement: $p = .001$, Aspect: $p = .000$). Agreement was found to be the best preserved category (80% correct), whereas Aspect was the most severely affected category (46% correct). GL performed significantly lower on Aspect, compared to Tense and Agreement (see Table 4). Likewise, the comparison (by Binomial test) between his raw data and the chance level for this task (50%) revealed that his performance was at chance on Aspect and above chance on Agreement and Tense.

4.4 Results from the picture-pointing task

GL performed at ceiling on the picture-pointing task (Table 5). Thus, no dissociation was observed between subject and object questions. Certainly, the comparison (by Binomial test) between his raw data and the chance level for this task (25% given that each picture depicted four entities) revealed above chance performance ($p = .000$).

5. Discussion

In this study, I investigated the ability of a Greek-speaking agrammatic patient, GL, to comprehend semantically reversible canonical active and non-canonical passive sentences, subject-verb Agreement, Tense, Aspect, and wh-questions/CP, by means of four constrained tasks. No significant dissociation was found between passive and active sentences; GL performed above chance on both conditions. In contrast, he performed at chance on comprehending Tense (Experiment I). Agreement, Tense, and Aspect were found more-or-less impaired in the grammaticality judgment task, as GL performed significantly worse on all three categories compared to his control participant. His deficit, however, with respect to these categories was selective as he performed significantly worse on Aspect (chance performance) compared to Agreement and Tense (above chance). Last, GL had above chance

performance on the comprehension of *wh*-questions. I will first relate GL's data to the comprehension data of the three Greek-speaking agrammatic patients reported by Stavrakaki and Kouvava (2003) and Alexiadou and Stavrakaki (2006). Subsequently, I will discuss these patients' results in light of the relevant theories mentioned in the Introduction.

GL's results do not differ from SC's, Stavrakaki and Kouvava's (2003) first patient, as they both performed above chance on judging Agreement, Tense, and Spec, CP. Unlike GL, however, SC was not tested on Aspect, so it is unknown whether he was unimpaired in this low functional projection. SC's performance is at odds with all the relevant hypotheses mentioned in the Introduction. It is contra the TPH (Friedmann, 2006), as his Spec, CP seems to be well-preserved. It is contra the IFIH (Fyndanis et al., 2010, 2012; Nanousi et al., 2006; Varlokosta et al., 2006) because his performance on Tense is not worse than that on Agreement and, further, his performance on Neg-*ḗn* and Spec, CP (which both bear interpretable features) is above chance. Last, the DMA (Dickey et al., 2008; Thompson et al., 2002) does not appear to be in a position to explain the selective impairment in lexical retrieval/insertion, revealed by the Neg-*mín* – Neg-*ḗn*, and Spec, CP – C° dissociations.

GL's results differ from VF's, the second patient of Stavrakaki and Kouvava (2003), as VF performed above chance on all conditions. This is consistent with the literature that reports that comprehension is not always affected in agrammatic aphasia. Certainly, VF's pattern of performance is contra the TPH, TUH, and IFIH, but in line with the DMA (Dickey et al., 2008; Thompson et al., 2002).

Last, GL's data could not be directly compared with the data of KS, Alexiadou and Stavrakaki's (2006) patient, as the contrastive grammaticality judgment task employed by the authors did not target verbal morphology, as was the case with the present study. An observation that could be made, however, is that, while GL exhibited dissociations between functional projections (e.g., Aspect < Tense, Agreement, in the grammaticality judgment task), no dissociations emerged in KS, who performed above chance on all the projections tested. Her pattern of performance is contra the TPH (Friedmann, 2006), since this hypothesis would expect poor performance on the higher projections in the Greek syntactic tree. KS's comprehension data cannot be discussed in the context of the three other theories the present study is focusing on. This is so because the TUH (Wenzlaff & Clahsen, 2004, 2005) can only make predictions about the aphasic patients' performance on categories directly associated with the verbal morphology, while the IFIH (Fyndanis et al., 2010, 2012; Nanousi et al., 2006; Varlokosta et al., 2006) is relevant only when both categories with interpretable features and categories with uninterpretable features are tested. (Note that this hypothesis predicts better performance on "uninterpretable categories", compared to "interpretable categories". This distinction is not exploited in Alexiadou and Stavrakaki's (2006) study.) Last, the DMA (Dickey et al., 2008; Thompson et al., 2002) is relevant especially for studies testing both syntactic structure building abilities and morphological retrieval/insertion abilities. Alexiadou and Stavrakaki's (2006) study did not focus on the latter.

GL's results show that agrammatic patients can be impaired in the comprehension of canonical sentences –even irreversible–, such as "simple" active sentences that are used to test "demanding" functional categories like Aspect, which does not seem to be consistent with the TDH (Grodzinsky, 1995). Moreover, his results are contra this hypothesis because he performed above chance on reversible passives. This is in line with findings of other studies (e.g., Caramazza, Capasso, Capitani, & Miceli, 2005; Luzzatti, Toraldo, Guasti, Ghirardi, Lorenzi, & Guarnaschelli, 2001), which reveal that only a subgroup of agrammatics exhibits the pattern predicted by the TDH. GL's results are in contrast to the TPH (e.g., Friedmann, 2006), since his comprehension of Aspect, a category located low in the syntactic hierarchy of Greek, was found significantly more impaired than his comprehension of categories that are higher in the syntactic tree, such as Agreement and CP. GL's data do not support the TUH (Wenzlaff & Clahsen, 2004, 2005) because this hypothesis does not predict verbal morphology deficits other than those concerning Tense. GL, however, was impaired also in Aspect. Last, his results only partially support the IFIH (Fyndanis et al., 2010, 2012; Nanousi et al., 2006; Varlokosta et al., 2006), since the predictions of this hypothesis are confirmed only as far as the verbal morphology categories are concerned (Agreement > Aspect/Tense). GL had above chance performance on CP, which is in contrast to the IFIH. Hence, his results indicate that the TPH, TUH, and IFIH cannot be extended to the comprehension modality, at least not for all agrammatics. In contrast, GL's pattern of performance is consistent with the DMA (Dickey et al., 2008; Thompson et al., 2002), since he exhibited a selective deficit in the comprehension of verbal morphology (which affected Aspect) in the face of his well-preserved CP. Thus, in line with Dickey et al. (2008), GL's results show that at least some agrammatics are able to have access to the syntactic tree up to the highest layer and –at the same time– they may have a selective difficulty comprehending morphemes instantiating certain categories. It is likely, therefore, that what is genuinely affected in agrammatics like GL is not syntax, but

morphological insertion processes (Dickey et al., 2008), which is consistent with the DMA's (Halle & Marantz, 1993; Harley & Noyer, 1999) assumptions. On this assumption, in my understanding, in judgment tasks agrammatic patients often fail to retrieve the morpheme or the verb form that corresponds to the target value (which is determined on the basis of an adverbial, e.g. "past tense" on the basis of the adverb *yesterday*). Therefore, they are not able to compare the correct verb form they should have retrieved themselves with the verb form appearing in the experimental sentence, in order to successfully judge the grammaticality of the sentence. It seems plausible, however, that low performance in judgment tasks does not stem only from impaired morphological insertion/verb selection processes, but also from concurrent impaired feature-checking operations, as intact checking operations would block incorrect judgments (see Arabatzi & Edwards, 2002). While this may be the case with grammaticality judgment, one could challenge the view that comprehension deficits as well should be attributed to impaired insertion/retrieval processes. In tasks such as the sentence-picture matching task II of the present study, for example, all the sentences and verb forms/inflections are grammatical/correct; no temporal adverbials are present, thus participants are not required to judge the compatibility between adverbials and verb forms. They only need to correctly interpret the verb form/inflection as to its Tense value. Therefore, no retrieval/insertion processes are involved in this task. It appears, rather, that the poor performance on this task could be attributed to impaired integration processes (e.g., Fyndanis et al., 2010, 2012), that is, integration of strictly linguistic information, namely the Tense value expressed by each verb form/inflection, and information concerning the "reflexes" of this Tense value in the extralinguistic world (as depicted in the pictures).

To summarize, the comprehension results from Greek agrammatism reported and discussed here indicate that not only agrammatic production but also agrammatic comprehension is characterized by variability (e.g., Kolk, 2007). Furthermore, GL's data show that, at least in some agrammatic patients, the ability to project the syntactic hierarchy up to the highest layer (CP) may be preserved at the face of (selective) deficits in handling morphemes instantiating verb related functional categories, which is in line with data from other studies (e.g., Dickey et al., 2008), and compatible with the assumptions of Distributed Morphology (Halle & Marantz, 1993; Harley & Noyer, 1999) that the syntactic component operates separately from the morphological one. Certainly, more agrammatic patients have to be tested, so that the picture regarding the predominant patterns in agrammatic comprehension becomes more complete.

Acknowledgments

Many thanks go to the participants in this study. I express my gratitude to S. Varlokosta and K. Tsapkini for providing useful comments on earlier versions of this work. I am also grateful to C. Frangakis for his suggestions on statistics, as well as to I.M. Tsimpli, M. Nerantzini, and audiences at the 10th International Conference on Greek Linguistics (Komotini, Greece) and the 30th European Workshop in Cognitive Neuropsychology (Bressanone, Italy) for their comments. Last but not least, many thanks go to an anonymous reviewer for comments and suggestions that motivated me to significantly improve the quality of this work.

CONSTRUCTION, VALIDITY AND RELIABILITY OF THE STRATEGY INVENTORY FOR DICTIONARY USE (S.I.D.U)

Zoe Gavriilidou

Democritus University of Thrace, Greece

zoegab@otenet.gr

ABSTRACT

The purpose of the present paper is to examine the construction, validity and reliability of the Strategy Inventory of Dictionary Use (S.I.D.U). S.I.D.U is a 47-item self-report questionnaire which specifies four main areas of interest a) dictionary use awareness skills, b) strategies for dictionary selection and acquaintance with dictionary conventions, c) lemmatization strategies, and finally d) look up strategies. The method of multiple judges was adopted for the control of content validity of the pilot version of S.I.D.U. The test discriminated expert from non expert users in all four categories of strategies ($p < .001$). Internal consistency of the subscales and the overall scale of the S.I.D.U was checked and Cronbach alpha was found .97.

1. Introduction

Research in pedagogical lexicography has been disadvantaged by the lack of a standardized instrument to objectively assess the strategies employed by dictionary users while choosing and using a dictionary. The *Strategy Inventory for Dictionary Use* (S.I.D.U) is a 47-item self report instrument for assessing the reference skills needed for an effective dictionary look-up. The design, construction and content validity of S.I.D.U are presented here. Discriminatory validity between effective and non effective dictionary users was significant. The four subscales of dictionary use awareness, dictionary selection and acquaintance, lemmatization and dictionary search are shown to have good reliability and validity.

2. Construction

2.1 Test specification

The development of the test specification raised the question of how to define the effective dictionary user in order to construct the instruments' items. A functional approach might be to consult all previous literature in detail and try to make a list of the reference skills of the successful dictionary user. This was the method adopted for the construction of S.I.D.U. Fortunately, there is a substantial body of research on the characteristics of good dictionary users or the strategies required for an effective dictionary look-up. Two different kinds of research have been consulted: theoretical or empirical papers presenting detailed descriptions or taxonomies of the reference skills (or strategies) that dictionary users should demonstrate for a successful dictionary search (e.g Béjoint 1981; Scholfield 1999; Scholfield 1982; Bogaards 1994; Roberts 1997; Hartmann 1999; Nesi 1999; Nation 2001; Hartmann and James 2002; Thornbury 2002; Lew and Galas 2008; Prichard 2008) and empirical papers investigating the reference skills, misuse and errors of dictionary users during dictionary look up (Béjoint and Moulin 1987; Maingay and Rundell 1987; Neubach and Cohen 1988; Nuccorini 1992; Nuccorini 1994; Nesi and Meara 1994; Christianson 1997; Harvey and Yuill 1997; Wingate 2004; Elola, Rodríguez-García and Winfrey 2008; Petrylaitė, Vėžytė and Vaškelienė 2008; Gavriilidou 2010, 2011).

Starting with the first category of papers, Bejoint (1981) mainly investigated the reasons for using dictionaries reported by French students and discussed the way in which these students actually used dictionaries. He claimed that two are the basic reference skills during dictionary search: users have to be able to find the lexeme they are looking for, by finding either the right entry or the right subdivision

of an entry. Then they must be able to retrieve the specific piece of information they need (spelling, pronunciation, meaning, etc.).

Scholfield (1982) suggested that effective dictionary use requires a number of steps to be performed correctly, an amount of prior knowledge, e.g. rules of English, dictionary conventions, etc., a constant testing of hypotheses and finally inferencing. According to the author the steps required during looking up a word in a dictionary are seven:

- 1) Locating the unknown word or phrase in a text
- 2) Finding the citation form in case of inflected words
- 3) Searching the unknown word in the alphabetic list
- 4) Searching compound words or idioms by looking up each main element of them and derived forms by looking up the stem entry
- 5) Reducing multiple senses of polysemous words by elimination
- 6) Understanding the definition of the unknown word by integrating it in context
- 7) In case that the desired meaning of the unknown word doesn't exist in the dictionary, inferring of the appropriate meaning based on the list of meanings provided in the entry.

A number of skills such as awareness of dictionary lay-out, alphabetic sequencing or grammatical knowledge are connected with each one of the above mentioned steps. The steps described in Scholfield 1982 are also adopted in Bogaards (1993).

Roberts (1997) claims that efficient dictionary use implies obtaining the expected results, on the one hand, and accomplishing this in the shortest period of time possible. For him, the effective user has to be aware of the various categories of information that can be found in dictionaries, the overall ordering of these categories, dictionary types, and the specific categories of information found in different dictionary types.

Hartmann (1999) formulates recommendations with regard to the reference needs and reference skills of university students of foreign languages and the availability of dictionaries and other kinds of reference works, particularly for the European languages and argues that not much is known about dictionary reference skills themselves.

In her 1999 study, Nesi asserts that 97% of students entering English higher education have no dictionary skills at all and proposes a six-stage taxonomy of reference skills (before the study, before dictionary consultation, locating entry information, interpreting entry information, recording entry information, understanding lexicographical issues). Her detailed taxonomy includes among others reference skills such as knowing what types of dictionary exist, and choosing which dictionary/ies to consult and/or buy, deciding whether dictionary consultation is necessary, deciding on the appropriate form of the look-up item, understanding the structure of the dictionary, finding multi-word units, distinguishing relevant from irrelevant information, knowing lexicographical terminology, knowing of alphabetical sequencing, awareness of dictionary features and lay out, ability to select the correct meaning, etc.

Nation (2001) distinguishes between the steps involved in a successful dictionary search and the personal skills required by effective dictionary users. More precisely he proposes four distinct steps during both receptive and productive use of dictionaries. The receptive use involves a) analysing the context of the unknown word, b) finding the correct entry, c) choosing the right sub-entry, and d) applying the meaning to the original context in order to decide if the search was successful while the productive use includes: a) finding the wanted word form, b) checking the constraints on the use of the word c) finding out about its grammar and d) appropriately treat collocations. The individual skills required include recognising word classes and inflected forms, alphabetising, and understanding the symbols and lay-out conventions of the dictionary.

Thornbury (2002) also presents a list of skills needed for successful dictionary use, which includes recognising features of dictionary layout, understanding the coding and abbreviations used in the entries, discriminating between the different meanings of a word, cross-checking translation equivalents given in bilingual dictionaries, using synonyms, antonyms and other information to find the best word for the intended meaning and finally inferring the spelling of an unfamiliar word after hearing it.

Hartmann and James in their *Dictionary of Lexicography* (2002) suggested that, in order to use dictionaries, users need a) certain skills defined as “the abilities required for finding the information being sought” – and b) specific training. According to them, the most basic skill for using a dictionary is alphabetical sequencing.

Finally, Lew and Gallas (2008) adopt a detailed taxonomy of the dictionary strategies. They classify the reference skills in four classes a) REFERENCE, which includes knowledge of alphabetical

ordering; the ability to use a dictionary for equivalents, definitions, spelling, pronunciation and obtaining grammatical information; locating words using initial letters, b) INFERENCE which includes the ability to establish and interpret parts of speech; the ability to correctly interpret meanings; finding and handling meanings; grammatical awareness, c) UNDERSTANDING DICTIONARY CONVENTIONS which consists of the awareness of dictionary features and layout knowledge of phonetic symbols; knowledge of parts of speech; word formation; derivatives; past forms; countable and uncountable nouns; awareness of idiomatic expressions; awareness of phrasal verbs; pronouns and d) ACQUIRING EXTRA INFORMATION the ability to obtain socio-cultural information.

However, not all dictionary users demonstrate reference skills such the ones described above. Empirical research suggests that even experienced language learners or pupils use the dictionaries ineffectively. For example, Bejoint & Moulin (1987) provided a list of positive and negative strategies and claimed that strategy use depends on the performed task and the learners' profile. Maingay and Rundell (1987) forwarded a detailed classification of students' errors in encoding activities. Neubach and Cohen (1988) reported a series of problems faced by six subjects of different proficiency levels during a dictionary-use-based task in comprehension. The reported problems were the following: 1) reading only the first definition in the monolingual dictionary, 2) encountering a problem with vocabulary in a definition in the monolingual dictionary, 3) encountering a problem with terminology in the monolingual dictionary, 4) encountering problems in alphabetic sequencing – especially internal to the word being sought, 5) not finding the unknown word. These problems clearly demonstrate users' lack of reference skills. Nuccorini (1992) found that her sample, which consisted of students and teachers were able to locate successfully the research items. She notices however that they had problems with the dictionary microstructure. In her 1994 paper, she found that students committed erroneous searches when they had to look up polysemous and homonymic items, derivatives, compounds, idiomatic expressions and phrasal verbs. Nesi & Meara (1994) examined the errors of adult learners who were asked to construct phrases with unknown words that they had looked up and found that users perform superficial searches and tend to pick out familiar elements of the entry which are however irrelevant. Christianson (1997) found that proficiency does not seem to play a role in the sophistication of strategy use. He suggests that successfulness of strategy depends on other factors such as the writing context and the given word or phrase been looked up. A recurrent source of problem was that the subjects did not pay attention to the example sentences. Also a cause of problems was lack of understanding of the grammar information coded in the dictionaries. Harvey & Yuill (1997) studied the use of monolingual pedagogical dictionaries during writing. They found that the majority of dictionary searches were successful. Their sample wasn't acquainted with the dictionary abbreviations, especially the ones indicating grammatical information and faced problems when the entry had many sections, or when the unknown word was a compound or idiom. Wingate's (2004) data revealed "superficial and partial reading of dictionary entries" behaviour which accounted for unsuccessful dictionary look-ups. Elola, Rodríguez-García & Winfrey (2008) studied dictionary use and vocabulary choices during L2 writing and found that her sample face problems with the look up of abstract and domain-specific words, collocations and fixed expressions, lexical items of multiple grammatical categories and discourse markers. Petrylaitė, Vaškelienė, Vėžytė (2008) highlighted the respondents' lack of awareness of the advantages of proper dictionary consultation skills, as well as their overconfidence in some cases in their dictionary skills. Gavrilidou (2010) found that her sample adopts positive look up strategies or strategies for appropriate dictionary selection, but faces problems with lemmatization strategies. Finally, Gavrilidou (2011) studied the receptive dictionary use of Greek university students and reported problems with metaphoric meanings of words, idioms and compounds.

After consulting the relevant literature thoroughly, an exhaustive list including all reference skills cited in the literature was prepared. The reference skills of the total list were then classified in the following four categories: a) dictionary use awareness skills, in other words skills referring to the acquaintance with the situations in which a dictionary can be used, b) strategies for dictionary selection and acquaintance with dictionary conventions. This category includes strategies either for selecting the appropriate dictionary or for using effectively the dictionary conventions as a guidance during dictionary look up, c) lemmatization strategies, in other words strategies for selecting in which entry to look up the information needed, and finally d) look up strategies, for instance strategies employed for selecting effectively the relevant information. Thus S.I.D.U specified four main areas of interest.

2.2 The Pilot Version

The pilot version of the S.I.D.U was a self-report five Likert-scale questionnaire of 52 items. More precisely, 18 questions were assessing the dictionary use awareness, 14 questions were tracing the

strategies for dictionary selection and acquaintance with dictionary conventions, 5 questions were measuring the lemmatization strategies, and finally 15 questions were assessing the look up strategies. The pilot version was checked for its content and discriminatory validity as well as for its reliability. The results are presented in the following part.

3. Content Validity

Content validity is the degree to which elements of an assessment instrument are relevant to and representative of the targeted construct for a particular assessment purpose (Haynes, Richard and Kubany 1995). A widely used and recommended by psychometricians method of measuring content validity is the use of multiple judges (Lawshe 1975; Hambleton and Rogers 1991; Haynes, Richard and Kubany 1995). Every element of an assessment instrument is judged by multiple experts. Lawshe (1975) proposed that each of the experts respond to the following question for each item: "Is the skill or knowledge measured by this item 'essential,' 'useful, but not essential,' or 'not necessary' to the performance of the construct?" According to Lawshe, if more than half the panelists indicate that an item is essential, that item has at least some content validity.

The method of multiple judges was adopted for the measurement of content validity of the pilot version of S.I.D.U. The measurement was carrying out on a panel of 10 experts who judged the relevance and usefulness of each one of the 52 items of S.I.D.U. The 10 judges had to select 1 if they found the specific item essential, 2 if the specific item was 'useful, but not essential,' and 3 if the item was 'not necessary'. Only items which were assessed essential by more than half of the experts were kept. During that phase 5 items were eliminated. Thus the final version of the S.I.D.U consisted of 47 items (16 items assessing dictionary awareness, 12 items tracing strategies for dictionary selection and acquaintance with dictionary conventions, 5 items measuring the lemmatization strategies, and finally 14 items assessing the look up strategies) (see appendix I). The Quantitative indices of content validity of S.I.D.U were supplemented by qualitative feedback by the experts, which included additions and rewordings in four items.

Statistical analyses of data gathered with S.I.D.U included an examination of the reliability of the instrument and its ability to discriminate between effective and ineffective dictionary users.

4. Discriminatory Validity

Discriminatory validity is the ability of a psychometric instrument to show significant differences between subgroups with different characteristics. The ability of S.I.D.U to discriminate the effective from the ineffective dictionary users was checked.

4.1 Sampling

To check S.I.D.U's discriminatory validity, the sample consisted of 30 lexicographers which were considered as the group of expert users. Ineffective users were considered users with no dictionary experience. It was hypothesized that the nature of studies in departments such as the department of Electric Engineering, The Pre-Primary Education Department or the Physical Education Department does not involve frequently students with dictionary use activities. Thus, in order to select the sample of ineffective users, a randomly selected sample of 15 first year students of the Physical Education Department, 15 first year students of the Pre-Primary Education Department, and 15 first-year students of the Electric Engineering Department of the Democritus University of Thrace was interviewed. The interview included five questions tracing previous dictionary experience. It was found that the Physical Education Department students had the least dictionary experience. Consequently, the group of ineffective users consisted of 30 randomly selected first-year students of the Physical Education Department of the Democritus University of Thrace.

4.2 Statistics

In order to test whether the S.I.D.U can discriminate the effective from the ineffective dictionary users a T-test analysis for independent samples was performed. The results showed that in all four categories of strategies the expert users had a significantly higher score (dictionary awareness strategies $t=6,99$,

$p < .001$, dictionary selection and acquaintance with dictionary conventions strategies $t = 8.12$, $p < .001$, lemmatization strategies $t = 6.25$, $p < .001$, and finally look up strategies $t = 6.72$, $p < .001$). Consequently, the S.I.D.U classified effectively the subjects into two categories.

5. Reliability

5.1 Sampling

Reliability is how consistently a test measures what it attempts to measure. To check S.I.D.U's reliability, the sample consisted of 30 high-school pupils aged 12-15 years, 30 lyceum pupils aged 15-18 years, 30 professors at the secondary education and 30 university students of the department of Greek literature of the Democritus University of Thrace (total 120 subjects).

5.2 Statistics

A reliability analysis (Cronbach's alpha) was performed to examine the internal consistency of the S.I.D.U. The Cronbach's A was .97.

6. Conclusions and further investigation

This study allowed us to evaluate the reliability and the discriminatory validity of S.I.D.U which measures the use of strategies proposed in the literature as employed during effective dictionary use and specified the four categories of strategies which optimize the assessment of dictionary use.

The findings of the present study show that S.I.D.U is the first reliable and valid instrument for use in assessing dictionary use. Its discriminatory validity proved to be high.

The major application of S.I.D.U is to assess the dictionary use strategies employed by students or pupils in order to collect reliable data for the design of special curricula for dictionary use training. For ease of interpretation of the results, four subscales are designed in a manner to allow the profiling of dictionary users. It can also be used to assess the improvement in dictionary use as a result of the application of these curricula in specific target groups. Another possible use is for research purposes on pedagogical lexicography.

With its ease of administration and its four subscales, S.I.D.U promises to offer a psychometrically sound measure with which to assess effective dictionary use.

Finally, more testing of a normative sample with S.I.D.U is needed in order to provide reference ranges for its scores when administered to dictionary users and thus be able to offer a standardized version of that self-report questionnaire.

29. Όταν συναντώ μια άγνωστη λέξη σε ένα κείμενο, προσπαθώ να σκεφτώ με ποιον τύπο να την αναζητήσω στο λεξικό	1	2	3	4	5
30. Όταν συναντώ μια παροιμία ή μια έκφραση που δεν καταλαβαίνω, ψάχνω για τη σημασία της στο λεξικό στο λήμμα που αντιστοιχεί στο πρώτο ουσιαστικό ή επίθετο της παροιμίας	1	2	3	4	5
31. Όταν δεν βρίσκω μια παροιμία ή μια παγιωμένη έκφραση στο λήμμα που νόμιζα ότι βρισκόταν ξεκινώ μια νέα αναζήτηση	1	2	3	4	5
32. Όταν ακούω μια λέξη που δεν καταλαβαίνω, σκέφτομαι τους πιθανούς τρόπους ορθογραφίας της και την αναζητώ σε διαφορετικά σημεία του λεξικού	1	2	3	4	5
33. Όταν δεν βρίσκω μια λέξη στο σημείο που πιστεύω πως θα βρισκόταν, ξεκινώ νέα αναζήτηση με άλλα κριτήρια έως ότου τη βρω	1	2	3	4	5
34. Αναζητώ ένα κύριο όνομα σε ειδικό πίνακα στο τέλος ή σε κάποιο άλλο σημείο του λεξικού	1	2	3	4	5
35. Για να δω πώς χρησιμοποιείται μια λέξη στο λόγο βοηθούμαι από τις ειδικές συντομογραφίες χρήσης που υπάρχουν στο λήμμα	1	2	3	4	5
36. Όταν αναζητώ μια λέξη που αρχίζει από Ε, ψάχνω στο 1 ^ο τέταρτο των σελίδων του λεξικού, γιατί το Ε είναι από τα πρώτα γράμματα της αλφαβήτας	1	2	3	4	5

37. Όταν αναζητώ μία λέξη από Λ ανοίγω στο μέσο του λεξικού μου	1	2	3	4	5
38. Όταν αναζητώ μια λέξη, έχω στο μυαλό μου από τι αρχίζει η λέξη αυτή και ψάχνω εκεί που νομίζω πως βρίσκονται λέξεις που αρχίζουν από το συγκεκριμένο γράμμα	1	2	3	4	5
39. Όταν αναζητώ μια λέξη, ανοίγω λίγο το λεξικό και ελέγχω αν είμαι κοντά στο ζητούμενο ψηφίο	1	2	3	4	5
40. Όταν αναζητώ μια λέξη, καθοδηγούμαι από τα κεφαλάρια	1	2	3	4	5
41. Ανοίγω το λεξικό και διαβάζω τις λέξεις μόνο όταν είμαι σίγουρος/η πως βρίσκομαι στη σωστή σελίδα	1	2	3	4	5
42. Όταν αναζητώ μια λέξη, την έχω διαρκώς στο μυαλό μου κατά τη διάρκεια της αναζήτησης	1	2	3	4	5
43. Όταν διαπιστώσω ότι η λέξη που αναζητώ έχει πολλές διαφορετικές σημασίες, ελέγχω μία προς μία όλες τις σημασίες βοηθούμενος/η από τα παραδείγματα	1	2	3	4	5
44. Όταν βρω τη λέξη που με ενδιαφέρει επιστρέφω στο κείμενο για να επιβεβαιώσω από τα συμφραζόμενα ότι βρήκα την κατάλληλη σημασία	1	2	3	4	5
45. Πριν χρησιμοποιήσω στο κείμενο που γράφω μια λέξη που βρήκα στο λεξικό αναζητώ όλες τις γραμματικές πληροφορίες (κλίση, σύνταξη) και πληροφορίες χρήσης για να είμαι σίγουρος/η ότι τη χρησιμοποιώ σωστά	1	2	3	4	5
46. Βοηθούμαι από τα συνώνυμα ή τα αντίθετα για να βρω τη σημασία της λέξης που με ενδιαφέρει	1	2	3	4	5
47. Αναζητώ έναν εξειδικευμένο όρο σε ένα λεξικό ορολογίας	1	2	3	4	5

A PROPOSAL FOR A METADATA MODEL FOR LANGUAGE RESOURCES

ABSTRACT

This paper presents a metadata model for the description of language resources proposed in the framework of the META-SHARE infrastructure, aiming to cover both datasets and tools/technologies used for their processing. It places the model in the overall framework of metadata models, describes the basic principles and features of the model, elaborates on the LR type 'corpora' as an exemplification case and concludes with work to be done in the future for the improvement of the model.

1. Introduction¹

The importance of Language Resources (LRs) for language-related and language-based research and applications is undeniable. Language technology applications, in particular, such as multilingual information extraction, machine translation, automatic document indexing etc., include LRs as critical components. Even language technologies that consist of language independent engines rely on the availability of language-dependent knowledge under the form of LRs for their real-life implementation. It has also been proved that a critical mass of LRs can make advancement in language research possible and quicker (Calzolari, Quochi, and Soria 2011).

Language data collection has started in the 50's with a shift of focus from the native speaker's intuition to the actual use of language. Technological advancements and the advent of the web have moved the attention of researchers to the quick and efficient analysis of huge bulks of data. Digital repositories constitute a valuable tool in the effort of publishing, archiving, discovery and long-term maintenance of huge amounts of digital data (publications, datasets, multimedia files, and even processing tools and services), as they provide the infrastructure for describing and documenting, storing, preserving, and making this information publicly available in an open, user-friendly and trusted way.

META-SHARE (www.meta-share.eu) is an open, integrated, secure and interoperable exchange infrastructure dedicated to LRs; it serves as a marketplace where LRs are documented, uploaded and stored in repositories, catalogued and announced, downloaded, exchanged and discussed, aiming to support a data economy. META-SHARE brings together knowledge about LRs and related objects and processes and fosters their use

- by providing easy, uniform, one-step access to LRs through the aggregation of LR sources into one catalogue,
- by facilitating the LRs search and retrieval processes,
- by facilitating the evaluation of LRs through comparison between similar LRs,
- by encouraging (re-)use and new use of LRs through the monitoring of actual LRs use.

¹ This paper presents work done in the framework of the project T4ME, funded by DG INFSO of the European Commission through the 7th Framework Program, Grant agreement no.: 249119. Many thanks are due to all the colleagues of the META-SHARE metadata working group.

The adoption of a *uniform metadata schema*, i.e. a common terminology for the external description of LRs, is crucial to the success of the endeavour.

In the context of META-SHARE, the term *metadata* refers to descriptions of LRs, encompassing both *data* (textual, multimodal/multimedia and lexical data, grammars, language models etc.) and *technologies* (tools/services) used for their processing.

2. Design principles for the metadata model

The metadata descriptions constitute the means by which LR producers describe their resources and LR users identify the resources they seek. Thus, the META-SHARE metadata model forms an integral part of the search and retrieval mechanism, with a subset of its elements serving as the access points to the LRs catalogue. In this effort, we have built upon three main building blocks:

- (a) user requirements, collected through a survey conducted in the framework of the project (Federmann et al. 2011),
- (b) the recommendations of the e-IRG report of ESFRI (e-IRG 2009, <http://www.e-irg.eu>), in what concerns purpose of usage, aims and features²,
- (c) a study of widespread metadata models in HLT and LR catalogue descriptions. The schemas and catalogues taken into account include:
 - the Corpus Encoding Standard (CES, <http://www.cs.vassar.edu/CES/>) & its XML version (XCES, <http://www.xces.org/>), which instantiates the EAGLES CES DTDs for linguistic corpora;
 - the Text Encoding Initiative (TEI, <http://www.tei-c.org/index.xml>), which develops and maintains a standard for the representation of digital texts. TEI has most notably provided guidelines for the encoding of machine-readable texts, mainly in the fields of humanities, social sciences and linguistics;
 - the Open Language Archives Community (OLAC, <http://www.language-archives.org/>), which aims at developing best practices for the digital archiving of language resources, and at implementing a network of interoperating repositories and services for hosting and accessing such resources;
 - the Dublin Core Metadata Initiative (DCMI, <http://dublincore.org/>), which, as part of its mission, develops and maintains specifications in support of resource description;
 - the ISLE MetaData Initiative (IMDI, <http://www.mpi.nl/IMDI/>), which is a metadata standard for the description of multi-media and multi-modal language resources;
 - the metadata model proposed by the European National Activities for Basic Language Resources project (ENABLER, <http://www.ilsp.gr/en/infoprojects/meta?view=project&task=show&id=121>);
 - the metadata-related activities of the CLARIN project (Common Language Resources and Technology Infrastructure, <http://www.clarin.eu/external/>), aiming to offer persistent services and provide easy access to language processing resources;
 - the Basic Metadata Description (BAMDES), a minimal metadata set used for harvesting purposes by the Harvesting Day initiative (<http://theharvestingday.eu/>), a routine in which a robot collects metadata descriptions of resources and tools, as published at their websites;
 - the European Language Resources Association (ELRA, <http://www.elra.info/>) resources, namely the ELRA Catalogue (resources distributed by ELRA), the ELRA Universal Catalogue (which comprises information regarding LRs identified all over the world) and the LRE map (a mechanism intended to monitor the use and creation of LRs by collecting information on both existing and newly-created resources);
 - the Linguistic Data Consortium (LDC, <http://www ldc.upenn.edu/>) catalogue of available resources. The LDC supports language-related education, research and technology development by creating and sharing linguistic resources;
 - and last but not least, the ISO 12620 – Data Category Registry (ISocat DCR, (ISO 12620 2009), <http://www.isocat.org/>), which defines widely accepted linguistic concepts, including metadata for the description of language resources.

² For a detailed presentation, cf. (Gavrilidou et al. 2011).

The study of these initiatives revealed that, although general trends can be spotted, there is no consensus as regards LR typology. The various typologies present different views on LR categorisation, and two tendencies have been attested in practice: on the one hand there are well-structured typologies for the classification of resources, and on the other hand there is the trend for free categorisation, whereby the provider declares the type of the resource. The first solution lacks flexibility (some resources might not fit into the predefined types), while the latter lacks uniformity and consistency. Furthermore, diverging uses of terminology hinder interoperability between metadata schemas.

The concept of *resource type* seems to be crucial to all metadata schemas and cataloguing practices, given that it constitutes the basic concept for the organization of language resources and determines a critical subset of elements related to their description. As regards the set of descriptive elements selected by each schema, consensus up to a certain degree is attested. The naming of the elements may vary but fundamental properties of LRs (e.g. identification details, resource name, free-text description) are in general present in all schemas.

From the standards and models surveyed, the DCMI standard is the most widespread metadata initiative, going back to the 90's with the advent of the internet, originating in works of library and archive cataloguing. The DC metadata element set refers to a basic set of 15 elements; refinements to this set have already been made and are documented in the DC Metadata Terms. As for LR typology, DC obviously is not restricted to LRs, and, since it was not built for this specific purpose, its terms are not sufficient for the description of language resources.

Inspired by the advantages and disadvantages of the surveyed standards, the basic principles of the METASHARE model were formulated.

- The semantic discrepancies between the standards dictated the need for **semantic clarity**, i.e. clear articulation of a term's meaning and its relations to other terms.
- The fact that certain standards focus on specific language resource types but do not cover all, led to the formulation of the principle of **expressiveness**, i.e. the ability of the model for successful description of any type of resource.
- The differing tendencies attested as regards granularity led to the principle of **flexibility**, i.e. the possibility for exhaustive but also for minimal descriptions.
- The constant emergence of new types of resources which were not covered by existing standards dictated the principle of **extensibility**, i.e. catering for future extensions, as regards the coverage of more resource types as they become available.
- Given that the metadata descriptions should be usable by other initiatives, the principle of **interoperability** is adhered to, which foresees mappings to widely used schemas (mainly DC, OLAC and ISO-DCR).
- Finally, the need for open metadata available to other initiatives led to the adoption of the principle of **harvestability**, allowing the harvesting of the metadata.

Based on these principles, the META-SHARE metadata model was designed and implemented as described in the following sections.

3. The metadata model essentials

As a general framework, the mechanism adopted for the META-SHARE metadata model is the *component-based* mechanism proposed by the ISO DCR (ISO 12620/2009), according to which semantically coherent elements are grouped together to form components (Broeder et al. 2008). *Elements* are used to encode specific descriptive features of the LRs, while *relations* are used to link together resources that are included in the META-SHARE repository (e.g. raw and annotated resources, a language resource and the tool that has been used to create it etc.), but also satellite resources such as standards used, related documentation etc.

Central to the model is the *LR taxonomy*, which allows us to organize the resources in a more structured way, taking into consideration the specificities of each type.

The set of all the components and elements describing specific LR types and subtypes represent the *profile* of this type. Obviously, certain components include information common to all types of resources (e.g. identification, contact, licensing information etc.) and are, thus, used for all LRs, while others (e.g. components including information on the contents, annotation etc. of a resource), differ

across resource types. The user is presented with proposed profiles for each LR type, which can be used as templates or guidelines for the completion of the metadata description of the resource.

In order to accommodate flexibility, the elements belong to two basic levels of description (stepwise approach):

- an initial level providing the basic elements for the description of a resource (*minimal schema*), and
- a second level with a higher degree of granularity (*maximal schema*), providing detailed information on a resource and covering all stages of LR production and use.

The minimal schema contains those elements considered indispensable for LR description (from the provider's perspective) and identification (from the consumer's perspective). It takes into account the views expressed in the user survey concerning which features are considered sufficient to give a sound "identity" to a resource. LRs producers are asked to fill in at least the minimal schema and, thereafter, enrich the descriptions of their LRs with recommended and optional elements, should they wish to do so.

In addition, the schema specifies the type allowed for all elements³ (e.g. if the values are of type *string*, *number*, *closed set of values* etc.).

4. The META-SHARE ontology

META-SHARE takes a global view on resources, aiming at providing users not only with a catalogue of LRs but also with information that can be used to enhance their exploitation. For instance, research papers that document the production of a resource as well as standards and guidelines are informative for LR users and advisory for prospective LR producers.

In the proposed META-SHARE ontology (Figure 1), a distinction is made between LRs per se and all other related entities, such as reference documents related to the resource (papers, reports, manuals etc.), persons / organizations involved in its creation and use (creators, distributors etc.), related projects and activities (funding projects, activities of usage etc.) and licences (for the distribution of the LRs).

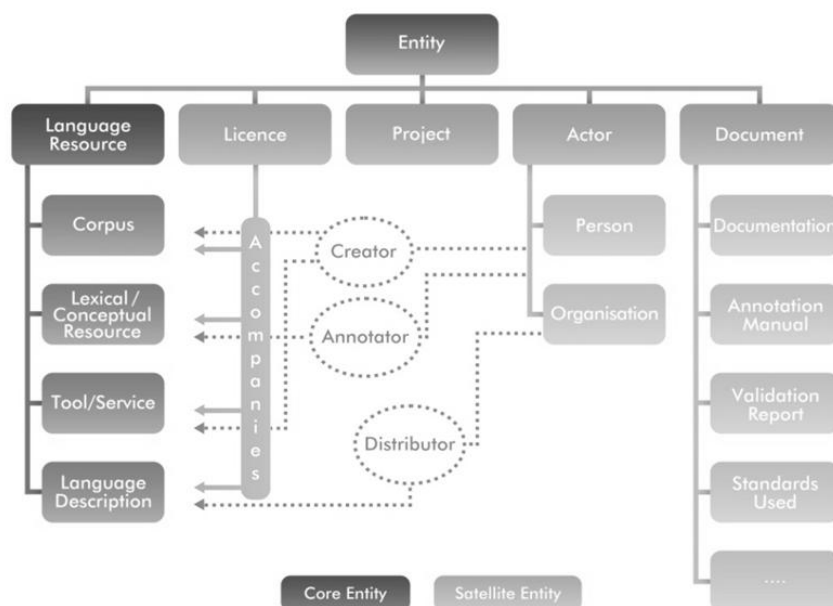

Figure 1 META-SHARE ontology

Thus, the META-SHARE model recognizes the following distinct entities:

- the *resource* itself, i.e. the LR being described, encompassing datasets and technologies,
- the *actor*, further distinguished into *person* and *organization*,
- the *project*,

³ Relations are also implemented as elements.

- the *document*, and
- the *licence*.

From these, however, the main interest of META-SHARE lies in resources, which constitute the central entity to be described; actors, projects, documents etc. are described when the case arises, i.e. when they are linked to a specific resource. Therefore, it is not expected from META-SHARE, for instance, to provide a bibliographical list of all documents that are relevant to the HLT domain, but only those documents that are related to specific resources (e.g. articles describing the creation and/or use of a resource, documentation manuals, annotation guidelines etc.).

Consequently, the META-SHARE metadata model aims at covering only LR per se. For all other entities of the ontology, metadata schemas and formats that have been devised specifically for them (e.g. BibTex for bibliographical references) have been taken into account.

5. Proposed LR taxonomy

The study of existing LR typologies (Gavriliadou et al. 2011) has revealed their diversity, which hampers the request for interoperability and jeopardizes the mandate of META-NET to provide a simple albeit descriptive schema for LR.

To encompass this issue, the META-SHARE LR taxonomy is based on intrinsic criteria, i.e. makes use of elements included in the schema. The proposed classification forms an integral part of the metadata model, whereby the types of LR (attributes and values) belong to the element set itself. A two-level hierarchy, with a coarse "main type" classification and further subclassifying features dependent on each type, is proposed. For the first level, the following four values are suggested for the element *resourceType*:

- *corpus* (including written/text, oral/spoken, multimodal/multimedia corpora)
- *lexical / conceptual resource* (including terminological resources, word lists, semantic lexica, ontologies etc.)
- *tool / service* (including processing tools, applications, web services etc. required for processing data resources)
- *language description* (including grammars, typological databases, courseware etc.).

Depending on the *resourceType* values, the LR types and subsequently the specific profiles (i.e. aggregations of components and elements) are defined.

The second element considered crucial for the description and classification of the resources is the physical medium (element *mediaType*). It is preferred over the written/spoken/multimodal distinction, as it has clearer semantics. Moreover, each medium type enforces for the description of the resources a particular set of features which differs across media.

A resource may consist of parts belonging to different types of media: for instance, a multimodal corpus includes a video part (moving image), an audio part (dialogues) and a text part (subtitles and/or transcription of the dialogues); a multimedia lexicon includes the text part, but may also include a video and/or an audio part; a sign language resource is also a resource with various media types (video, image, text). Similarly, tools can be applied to resources of different media types: e.g. a tool can be used both for video and for audio files. Thus, for each part of the resource, the respective feature set (components and elements) should be used: e.g. for a spoken corpus and its transcriptions, the audio feature set will be used for the audio part and the text feature set for the transcribed part.

The following media type values and combinations are foreseen:

- *text*: used for data resources with only written medium (and modules of audio and multimodal corpora, see below), whether monolingual, comparable or parallel
- *audio* (+ text): the audio feature set will be used for a whole resource or part of a resource that is recorded as an audio file; its transcripts are to be described by the relevant *text* feature set
- *image* (+ text): the *image* feature set is used for photographs, drawings, images of sensorimotor data etc., while the *text* set can be used for the description of its captions
- *video*: moving image (+ text) (+ audio (+ text)): used for multimedia corpora, with *video* for the moving image part, *audio* for the dialogues, and *text* referring to the transcripts of the dialogues and/or subtitles.

Two additional values are introduced in the model, although they are not really distinct media type values: these correspond to numerical text resources (value *textNumerical*) and n-grams (value *ngram*). These are actually subtypes of text resources but they present further descriptive particularities due to their contents: numerical data (e.g. biometrical, geospatial data etc.) for the former and items with

probability measures for the latter. This categorization allows us to better treat them in the metadata model.

Finally, LR users can devise their own LR taxonomy, by browsing through the META-SHARE inventory using any of the metadata elements (and combinations thereof) as classification criteria. Thus, for instance *lingualityType* as an organizing feature can be used to bring together monolingual data resources and monolingual parts of multilingual ones. Similarly, *languageName*, *domain*, *format*, annotation features etc. can be used as different dimensions according to which the catalogue of LRs can be accessed.

6. Contents of the model

The core of the model is the *resourceInfo* component (Figure 2), which contains all the information relevant for the description of a LR. It subsumes components that combine together to provide the full description of a resource.

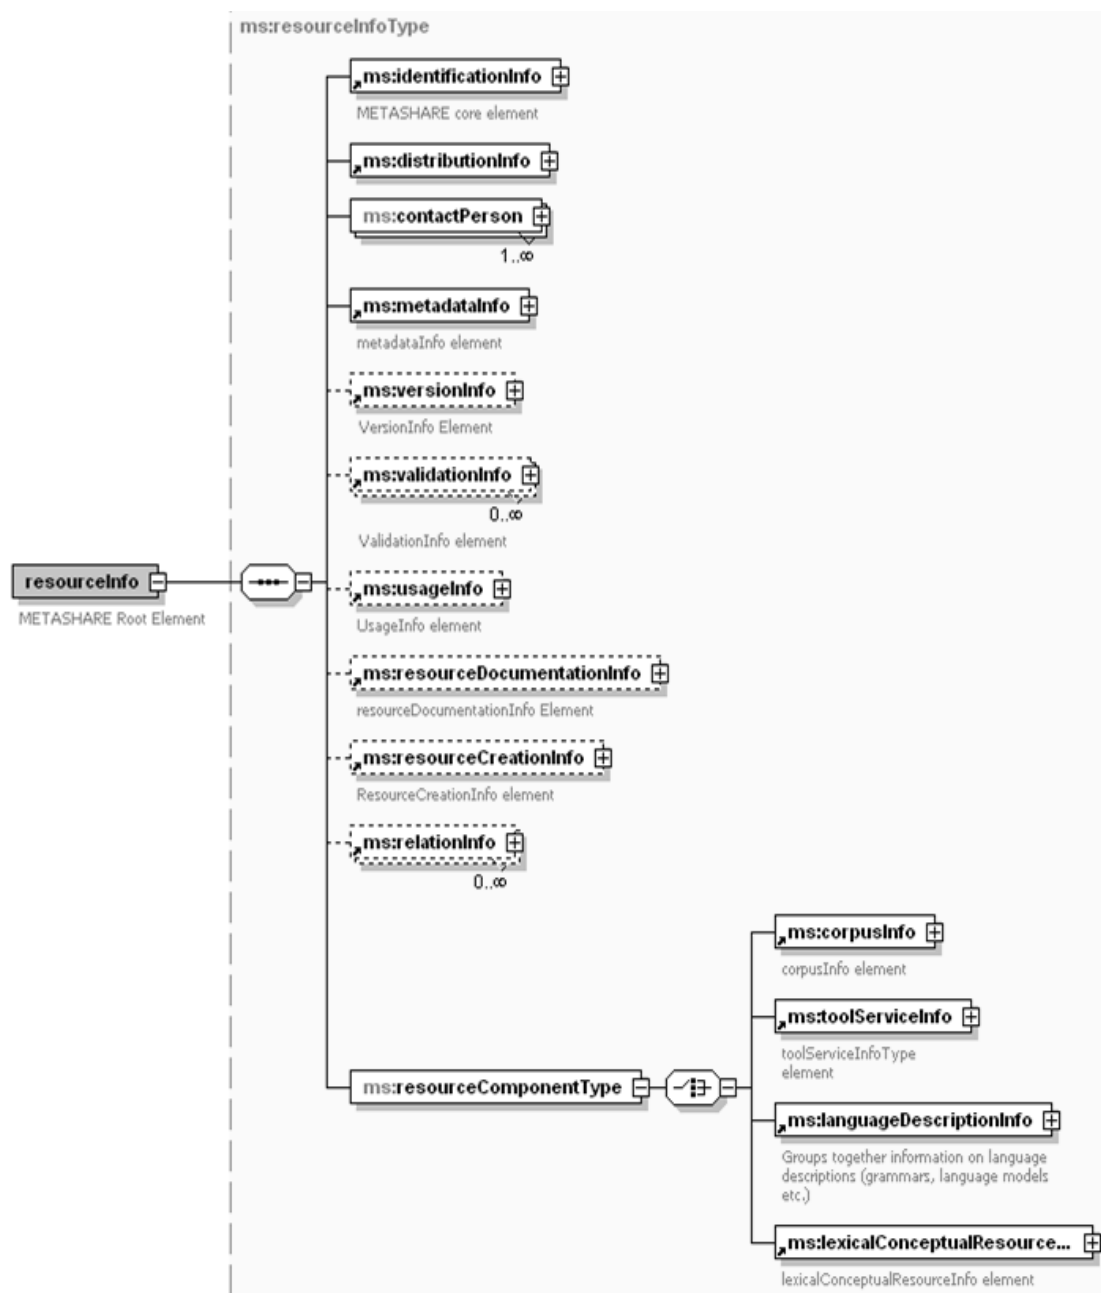

Figure 2 Common components for all LRs and resourceType components

A broad distinction can be made between the "administrative" components, which are common to all LRs, and the resource type- and media type-specific components.

The set of components that are common to all LRs are: *identificationInfo*, *distributionInfo*, *contactPerson*, *metadataInfo*, *versionInfo*, *validationInfo*, *usageInfo*, *resourceDocumentationInfo*, *creationInfo* and *relationInfo*. More specifically:

The *identificationInfo* component includes all elements required to identify the resource, such as the resource full and short names, the META-SHARE id (to be assigned automatically by the system) etc.; the *description* element is obligatorily used for the free text description of the resource contents.

Crucial is the information on the legal issues related to the availability of the resource, specified by the *distributionInfo* component, which provides a description of the terms of availability of the resource and its attached *licenceInfo* component, which gives a description of the licensing conditions under which the resource can be used.

The *contactPerson* component provides information about the person that can be contacted for further information or access to the resource.

The *metadataInfo* is responsible for all information relative to the metadata record creation, such as the catalogue from which the harvesting was made and the date of harvesting (in the case of harvested records) or the creation date and metadata creator (in case of records created from scratch using the META-SHARE metadata editor) etc.

All information relative to versioning and revisions of the resource is included in the *versionInfo* component.

The *validationInfo* component provides at least an indication of the validation status of the resource (with boolean values) and, if the resource has indeed been validated, further details on the validation mode, results etc.

The *usageInfo* component aims at providing information on the foreseen use of a resource (i.e. the application(s) for which it was originally designed) and its actual use (i.e. applications for which it has already been used, projects in which it has been exploited, products and publications having resulted from its use etc.).

The *resourceDocumentationInfo* provides information on publications and documents describing the resource; links to documents over the internet enhances this feature.

The *resourceCreationInfo* and its dependent components group together information regarding the creation of a resource (creation dates, funding information such as funder(s), project name etc.).

Finally, the *relationInfo* component allows the codification of relations that have not been foreseen by the metadata model; the resource providers have the chance to encode the relation type and the related resource.

The LR type-specific components are all located under the *resourceComponentType* component. Similarly, for each LR type, particular medium-dependent components are created to group together sets of features relevant to each LR/media type, given that media types and the recorded information for them differs across LR types; these are again grouped under an *xMediaType* component, where x stands for each of the LR type values (see Figure 3). The *resourceType* and *mediaType* elements encode the two classification axes of the schema, while each of the values of these two elements is associated with the appropriate component. The set of *resourceType* and *mediaType* components includes:

- *corpusInfo*, *lexicalConceptualResourceInfo*, *languageDescriptionInfo*, *toolServiceInfo* encode information specific to each LR type; the values *corpus*, *lexical/conceptualResource*, *languageDescription* and *toolService* are used for the element *resourceType* respectively
- *corpusTextInfo*, *corpusAudioInfo*, *corpusVideoInfo*, *lexicalConceptualResourceTextInfo*, *lexicalConceptualResourceVideoInfo* etc. provide information depending on the media type of each LR type and include the *mediaType* element with the values *text*, *audio*, *video* etc. accordingly.

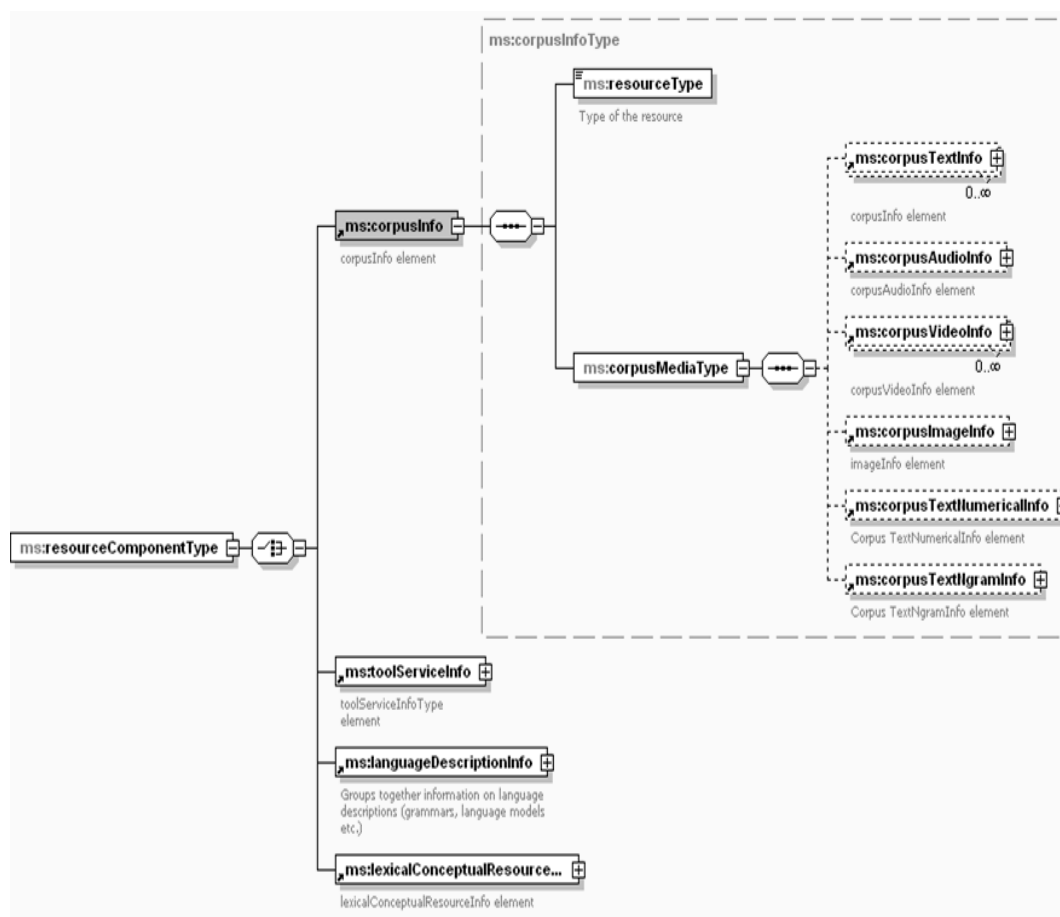

Figure 3 Components for corpora

Broadly speaking, the resource / media type-specific components cover the following types of information:

- contents: it mainly refers to languages covered in the resource, types of content (e.g. for images: drawings, photos, histograms, animations etc.), modalities included (e.g. written / spoken language, gestures, eye movements etc.), etc.
- classificatory information: it includes resource-type subclassification (e.g. subtypes of lexical/conceptual resources, tools/services etc.) as well as classification of the contents of the resource; this can be cross-media (e.g. domains, geographic coverage, time coverage etc.) as well as media-dependent (e.g. text type, audio genre, setting, etc.)
- formatting: file format, character encoding etc.; obviously, this information is more media-type-driven (e.g. different file formats for text, audio and video files)
- information on creation: this is to be distinguished from the *resourceCreationInfo* which is attached to the resource level; at the resource level, it is mainly used to give information on funding but also on anything that concerns the creation of the resource as a whole; at the media-type level, it refers to the creation of the specific resource parts, e.g. the original source, the capture and recording methods (e.g. scanning and web crawling for texts, vs. recording methods for audio files)
- performance: information regarding the performance of the resource; it is resource-type driven, given that the measures and criteria differ across resource types
- operation: information relevant to the operation requirements of the resource (e.g. the hardware and software prerequisites for running a tool/service)
- input and output: these are specific to tools/services; they can be used to provide information on the media type, format, language etc. that the tool/service can take as input and the resulting output
- finally, for multimedia resources, a special component, *linkToOtherMediaInfo*, is provided for linking between the various modules of the resource.

7. Minimal schema

The obligatory components and elements thereof that constitute the minimal schema are presented here below:

- *identificationInfo*: groups together information needed to identify the resource; the obligatory elements are the *resourceName*, the *meta-share id* and the *description*
- *distributionInfo*: groups information on the distribution of the resource; the element *availability* serves as a first indication of the terms of availability of the resource (with values *available*, *available-restrictedUse*, *available-unrestrictedUse*, *notAvailableThroughMetaShare*, *underNegotiation*); in case the resource is available, the component *licenceInfo* provides obligatorily further information regarding the licensing conditions under which the resource can be used (at least the license must be specified)
- *contactPerson*: groups information on the contact person; the only obligatory information is the *surname* and *email* of the person
- *metadataInfo*: groups information on the metadata record itself; the only mandatory element is the *metadataCreationDate*, which encodes the date of creation of the metadata record either from scratch or through harvesting; depending on the way the metadata record has been created (harvesting, editing, uploading etc.) further information can be optionally provided (e.g. metadata creator, original metadata link etc.)
- *resourceComponentType*: as aforesaid, this groups together the various LR-type-dependent components; thus, depending on the type of LR described, one of the following components is obligatory: *corpusInfo* for corpora, *lexicalConceptualResourceInfo* for lexical / conceptual resources etc.

Further obligatory components and elements are specified for each LR type. In general, the mandatory information is restricted to basic information so as not to intimidate metadata creators: size and languages for datasets, subtype for all (obviously with value sets depending on the resource type), level of encoding for language descriptions and so on.

The further characterisation of specific components and elements as "recommended" prompts the resource providers to input richer descriptions of their resources.

8. Corpora

This section presents the metadata schema, using corpora as an exemplary case.

Depending on the *mediaType*, at least one of the following components must appear: *corpusTextInfo*, *corpusAudioInfo*, *corpusVideoInfo*, *corpusImageInfo*, *corpusTextNumericalInfo* and/or *corpusTextNgramInfo* (cf. figure 3). Thus, for text corpora, the user will select to encode a *corpusTextInfo* component. A multimedia/multimodal corpus that includes videos, the transcribed dialogues thereof, the scenario used for the videos and the motion data captured by sensors (e.g. gloves, full-body equipment) and represented in the form of numerical text will require the encoding of a *corpusVideoInfo*, two *corpusTextInfo* and a *corpusTextNumericalInfo* components; the *linkToOtherMediaInfo* will provide the necessary information as to the linking and synchronization between them.

All of these components subsume further obligatory, recommended and optional components. As aforesaid, two types of information are obligatory for all of these components: *language(s)* and *size*. More specifically, as regards languages, *lingualityInfo* groups information regarding the number of languages included in the resource and the relation between them (e.g. monolingual, multilingual parallel corpus etc.), while *languageInfo* groups information respective to the specific languages and, if applicable, language varieties covered by the resource; in the case of languages, the two relevant elements (*languageId* and *languageName*) must conform to the IETF BCP47 standard (<http://www.rfc-editor.org/rfc/bcp/bcp47.txt>). Size information is recorded in the *sizeInfo* component; an effort to standardize the recorded information as far as possible has been made: thus, the *sizeInfo* component includes two elements, namely *sizeUnit* with values taken from an open controlled vocabulary⁴ and

⁴ "Open controlled vocabularies" are an important tool in the META-SHARE model as they bring together the advantages of two competing tendencies in metadata editing: controlled vocabularies allow for the standardization of information by providing a closed set of values from which users can choose but which cannot be easily updated and/or extended; user-added values, on the other hand, give more freedom but quite often the result is a list of similarly expressed values (e.g. *txt*, *TXT*, *text*, *texts*, *textual* etc. as alternatives for *text*). META-SHARE proposes the use of an intermediary tool, where users are provided with a set of predefined values for a given element, but

size, which specifies the size of the resource with regard to the *sizeUnit* measurement in the form of a number.

The *timeCoverageInfo*, *geographicCoverageInfo* and *domainInfo* can be used to provide information on the time, geographic and domain classification of the resource and/or resource parts. Further classification is also provided dependent on the *mediaType*: for the text corpora, *textGenre*, *textType*, *register* etc. are the suggested elements, for the video, *videoGenre* etc.

Creation information is also medium-type dependent: for instance, for audio and video resources (or modules), users can provide information on the recording equipment, the setting, the group of participants, the capturing equipment etc.

Further information can be provided for the *modalities* included in each resource module (in the *modalityInfo* component): so, for instance, for text resources, written vs. spoken language can be specified, while for audiovisual resources one can specify whether gestures, body movements etc. are contained.

The *formatting* information, which is important for the interoperability with tools and services, can also be encoded for each medium-specific part of the resource (e.g. the video part of the resource consists of WAV files, the text part consists of TXT and XML files etc.); character encoding is also included but obviously pertains only to text resources.

Finally, the *annotationInfo* component groups information on the *annotation* of the resource: annotation type, tool, method, process used, standards/best practices adopted etc. For each different type of annotation (e.g. lemmatization, semantic annotation, modality annotation etc.) the component is repeated, thus providing the correct linking between the various annotation details (e.g. which annotation tool has been used for which annotation type, in case of multiple annotation tools used).

9. Conclusions and future work

The current schema has been adopted and utilized for the description of 1,277 resources (datasets and tools), covering a broad variety of languages, resource and media types, available through META-SHARE. The model has been implemented as an XML schema, documented also in the form of a manual with detailed information, including definitions, examples and guidelines for the usage of the whole schema and each element (Desipri et al. 2012). Future work focuses on the completion of the schema as regards both breadth (i.e. coverage of more types) as well as depth (i.e. improvements on the schema based on LR providers' feedback).

ABSTRACT

This paper examines aspects of the linguistic repertoire of the bilingual in Greek and Turkish Muslim community of Rhodes. It is based on research conducted in an ethnographic framework and aims at exploring patterns of code alternation in everyday bilingual conversations among members of the community networks, as well as issues of identity as these can be approached based on the choices speakers of different social and age groups make during interaction. Based on the analysis, it will be shown that, a) aspects of the overall and sequential organization of bilingual conversations point to a micro-macro link between conversational practices and ethnographically documented structures of the community, namely community networks (Gumperz 1982; Milroy and Wei 1995; Georgalidou et al. 2011), and b) code alternation practices reflect not only aspects of the politics and management of the identity of the speakers as members of the same ethnic category, but also broader issues concerning the construction of youth identities as opposed to those of older generations.

1. Introduction

Firstly seen as a marginal social phenomenon, code-alternation has proven a rather universal aspect of the linguistic reality of most speech communities in the world and has become a major issue especially in what is defined as the socio-pragmatic approaches to bilingualism. Either as a consequence of the historical coexistence of dominant and minority ethnic communities and emigration, or even as a phenomenon that is connected to the teaching and use of languages that are defined as “foreign”, the systematic contact of different linguistic systems produces structural and communicative implications that only in the recent years of linguistic studies have been extensively studied. More specifically, in contemporary linguistics, and in particular in the context of the sociolinguistic and pragmatic approaches to actual language use, the study of bilingual conversation has altered the way we approach and evaluate phenomena such as the use of two (or more) languages by participants in the same communicative event, i.e. talk-in-interaction. Firstly seen as a non-systematic and rather problematic phenomenon concerning the communicative competence of bilinguals- or the lack of it- (Gafaranga 2007b), talk in more than one language has now gained a prominent place within socio- and pragmatic approaches to everyday talk (Georgalidou et al. 2010: 316). Prototypically defined as “a relationship of contiguous juxtaposition of semiotic systems, such that the appropriate recipients of the resulting complex sign are in a position to interpret the juxtaposition as such” (Auer 1995: 116), code-alternation has been examined for both the organizational parameters of bilingual talk-in-interaction and its impact on identity construction processes (Wei 1998; Auer 2005).

Based on Auer (1984, 1995), four patterns of conversational code alternation have been proposed that can be further seen as discourse related and participant related alternations. Pattern I concerns switching from code A to code B between utterances or in the same utterance and is considered the discourse related alternation or code alternation as a contextualisation cue (also see Gumperz 1982). Pattern II is considered the language preference related switching that activates the process of language

negotiation which leads to the prevalence of one language over another. Participants switch from code A to code B repeatedly until consensus is reached over the medium of conversation. Pattern III does not always permit the identification of any of the languages used as the base language of the interaction. It is a rather debatable case of alternation as it raises the question of a single bilingual medium as part of the overall organisation of the interaction over the juxtaposition of two distinct linguistic systems. Pattern IV, the intrasentential momentary switching that does not change the language of the interaction, is defined as transfer and is considered a participant related alternation pattern.

Gafaranga (2007), and Torres and Gafaranga (2002) have proposed a revised model of bilingual talk-in-interaction and code alternation patterns that sees alternation as an aspect of the overall organization of bilingual conversation. The more significant contribution of the model to the present discussion is the shift from the entity language to that of medium, be it monolingual or bilingual, as the central unit against which the discussion of code alternation practices can be placed. The shift of attention from the juxtaposition of two languages to the overall conversational organization, and the potential of the bilingual medium of being part of this organization, permits a more synthetic view of code alternation within a continuum of prototypical to less prototypical code alternation patterns (Georgalidou et al. 2010).

Seeing both models as complementary, we analyze conversations recorded during ethnographic research in the bilingual in Greek and Turkish Muslim community of Rhodes within a Conversation Analysis framework (Wei 2005). We examine aspects of the overall and sequential organization of bilingual conversations attempting a micro-macro link between conversational practices and ethnographically documented structures of the community, namely community networks (Gumperz 1982; Milroy and Wei 1995; Georgalidou et al. 2008). Also, we examine issues of identity as these can be approached based on the code alternation choices speakers of different age groups make during interaction.

2. The community

Muslims of Rhodes are Greek citizens of Turkish origin who have lived on Rhodes since 1522. In 1912, during the Italian occupation, and then again after the annexation of Dodecanese islands to Greece in 1947, the community underwent a major shift as far as power distribution is concerned. After being the dominant group during Ottoman times, they acquired the unofficial status of a minority community. Today's estimated population is 2500-3000 people on the island of Rhodes. Muslim students of Turkish origin attend public schools and the Turkish language is mainly used within the community, as it is not formally taught or used in transactions with the Greek-speaking majority neither in formal or informal contexts. As a consequence, in the last 60 years almost the entire Muslim community has shifted from near monolingualism in Turkish to bilingualism in Turkish and Greek.

As far as the linguistic repertoire of the community is concerned, older speakers use a Greek *contact vernacular* based on the local Greek dialect of Rhodes with substantial interference from Turkish. Later generations use a variety of Greek with less interference. This interference is gradually fading away to the near or completely native varieties of younger generations (Georgalidou et al. 2011). There are different proficiency levels in Turkish as well. Most members of the grandparent and parent generation are fluent in a local variety of Turkish, whereas contact with standard Turkish is mainly accomplished through television and occasional visits to Turkey. The local variety of Turkish also exhibits substantial interference from Greek (Kaili et al. 2009).

3. The research

We examine two subgroups of the community, one residing in the city of Rhodes and the other in a suburban settlement a few kilometers away from the city. We use ethnographic data collection procedures which allow us to obtain a realistic picture of patterns of language use and the informal social organization, i.e. networks operating in the community (Gumperz 1982; Milroy and Wei 1995; Georgalidou et al. 2011). Research has been going on for almost ten years. Linguistic data used for the present study were recorded during three family gatherings. They were recorded by one of the family members without the presence of the researchers. The aim was to collect linguistic data that would allow the analysis of code-choice and code-alternation patterns as exhibited by community members

who belong to different networks and age groups. The excerpts analyzed comprise of 31 hours of talk among members of three different families, two residing in the city and one in a suburban settlement.

4. The participants

Examples 1, 4 & 5 comprise of excerpts of conversations among members of two different families in the urban network. In the first family (FAM 1), the speakers belong to the grandparent (two speakers in their mid-sixties) and parent (one male speaker aged 30, the son of the couple) generations. In the second family (FAM 2), the speakers belong to the parent (the father aged 48-50 and the mother aged 45) and the children (one speaker in his early twenties, the son of the couple) generations. All examples involve mother/ wife (M/W)- father/ husband (F/H)- son (S) talk.

Examples 2, 3 & 6 comprise of excerpts of conversations among members of the suburban network who belong to the parent (the mother-M and the father-F, between 40 and 45) and children (three sisters aged 16-D3, 18-D2 and 20-D1, and Ercan, a 15 year old boy, distant relative of the family- FR) generations. They are all members of a close-knit neighborhood community network (FAM 3).

5. The analysis²

We analyze our data within a Conversation Analysis framework in examining the sequential development of interaction. We organize our examples based on the four patterns of code alternation as proposed by Auer (1995, 1998). We also refer to the overall/ medium approach as proposed by Gafaranga (2007). Taking the emic perspective as our point of departure, we attempt a link between the conversational strategies applied by the speakers, the management of the community linguistic resources and issues of identity. More specifically, we discuss the microstructures of code-alternation in connection to aspects of the identity of the speakers, such as their age and social status, as these are locally constructed in interaction.

Pattern I: The prototypical case of discourse organizational alternation. From code A to code B, between utterances or in the same utterance; code-alternation as a contextualisation cue (Gumperz 1982; Auer 1995, 1998).

Example 1 is a prototypical instance of Pattern I discourse organizational code alternation in order to mark a dispreferred sequence. It is part of a conversation conducted during a city family dinner event, the participants being an elderly couple and their 30 year old son (FAM 1, city dwellers). Mother and Son negotiate over the choice of the television program they are going to watch in Greek (turns 1 & 2). The alternation of codes by Mother marks the dispreferred sequence of rejecting the indirect request by her son to switch to a different television channel (turn 02), in turn 03.

Example 1 (FAM 1)

-
- 01 M Ti tha kanun afti?
 02 S Ego pali leo na dume ligo ti ginete ston kozmo.
 →03 M *Dur bakalım bu lahanayı ne açıyor böyle, içine ne dolduracak?*
- 01 M What are they going to do? (watching a magazino on Turkish tv)
 02 S I, on the other hand, say that we'd better see what is going on in the world. (indirectly requesting a switch to a Greek channel to watch the news)
 →03 M *Wait a minute. Let us see why he is opening this cabbage like this, what is he going to stuff it with?*
-

¹ Altogether, we have so far analyzed material based on more than 20 hours of conversations with and among 17 speakers at the urban setting, members of 4 partially overlapping exchange networks and 20 speakers at the suburban setting, all of them members of an overlapping kinship network.

² The English translation of the Greek/ Turkish conversations is only approximate.

Symbols used in the transcription: /: self-repair, //: interruption, (.): pause, ((): extralinguistic information, underlined segments: high pitch, =: latching, [: simultaneous speech, <x>: unintelligible segment

Code-choice in example 2 is also pragmatically relevant as it marks dispreferred sequences. Contrary to example 1, to reject the offer of food by both his host and hostess (turns 03, 04), Ercan uses their preferred language- not his- a choice that functions as redressive action (turns 07, 11). The older daughter of the couple on the other hand, switches to Greek, the overall preferred language by the younger members of the group, to reject her father's request for bread (turns 08, 10). In this example, the use of *same language* by the young guest of the family to mark the dispreferred sequence is in contrast to the choice made in the previous example. However, as opposition and disagreement are not necessarily dispreferred choices in conversations among family members (Kakava 2002), the marking of disagreement and rejection as non-dispreferred sequences by the younger daughter of the couple is done through switching to Greek. Choice of medium also constructs the variable status of the speakers, young guest versus family member.

Example 2- FAM 3

-
- 01 F: Ercan!
 02 FR: Hm?
 03 F: Bak. Şu mezeden acık al. Kokumluk. Dene len dene.
 04 M: Utanma bak utanma.
 05 F: Hani sofrada ekmek?
 06 M: Ekmek nerde?
 →07 FR: *Aka istemiyom ekmek.*
 08 D1: *A signomi exume patates den kani.*
 09 F: Kızım iki dilim kesin ekmek.
 10 D1: *ohi.*
 →11 FR: *Bişey olmaz tamam.*
- 01 F: Ercan!
 02 FR: Hm?
 03 F: Look. Take some of this delicacy. Take a bite. Just try it you.
 04 M: Don't be shy, don't be shy.
 05 F: Where is the bread on the table?
 06 M: Where is the bread?
 →07 FR: *Nop I don't want bread.*
 08 D1: *A, I'm sorry, we are having potatoes, it's not right.*
 09 F: My daughter cut two slices of bread.
 10 D1: *No.*
 →11 FR: *It's ok, no problem.*
-

Though structurally similar to Pattern II medium negotiation switching in terms of the organization of turn-taking and the continuous switching of languages (see example 4 below), example 3 is another instance of Pattern I discourse organizational switching. Mother switches to Greek to mark her disagreement to D2's evaluative rhetoric question as to the insignificance of a small amount of money (turn 08) by echoing D1's contribution in turn 06³. An important aspect of this excerpt is the lack of a base language as its overall organizational scheme (Auer 2000). Speakers of different age groups maintain their preferred languages throughout the episode as Mother's switching to Greek is only momentary, a fact established by the use of the Turkish epistemic copular -Dir at the end of her final contribution (turn 8). Language choice convergence or consensus does not seem to be an issue in this excerpt. Juxtaposition of codes however, is significant per se as the use of Greek in turns 02, 04, 06 & 07 by the younger members of the family does not form departure from Turkish as the established base language of the interaction. Rather, bilingual speakers of younger generation groups maintain Greek (or the bilingual medium as in examples 4 & 6) as their chosen medium, in contrast to speakers of the grandparent and parent generations who exhibit preference for the use of Turkish marked by their choice to initiate conversational episodes in it (examples 2, 3, 4, 6). Divergent language preference patterns form part of identity construction processes as they are means of claiming participation to different age groups and social roles, i.e. young versus old, child versus parent.

³ For a more detailed analysis see Georgalidou et al. 2010: 327-328.

Example 3- FAM 3

- 01 M: Sizde ne kadar eczanede?
 02 D1: *Ena trianda.*
 03 M: Biz ne kadar aldık şimdi?
 04 D1: *Ena peninda.*
 05 M: Sizde daha ucuz yani?
 06 D1: *İkosi lepta.*
 07 D2: *Mono?*
 →08 M: *Eh! İkosi lepta ikosi leptadır.*
- 01 M: How much is it at your pharmacy?
 02 D1: *One thirty.*
 03 M: How much have we bought it now?
 04 D1: *One fifty.*
 05 M: Is it cheaper at you ((your pharmacy)) that is?
 06 D1: *Twenty pence.*
 07 D2: *Only?*
 →08 M: *Eh! Twenty pence is twenty pence.*

Pattern II. From code A to code B repeatedly, until consensus is reached as on the medium of the exchange; the language preference related switching.

Example 4 is part of a young city family conversation (FAM 2, city dwellers). Unlike example 3, it is a typical case of pattern II code alternation in which consensus is sought and finally achieved over the medium of the interaction. Despite the fact that father initiates this conversational episode by means of Turkish, the son, a graduate of a Greek university in his early twenties, finally prevails in the language negotiation process and the father switches to Greek (turn 07). Yet, similarly to example 3, this is another instance of an identity construction process and language politics by an older speaker, who constructs parenthood via exhibiting preference for the we-code of the community. Irrespective of the outcome of the negotiation process, whenever one can be shown to be at work within talk-in-interaction, the contrast between younger and older generations of speakers is still constructed through their divergent choice of medium of talk.

Example 4- FAM 2

- 01 F Orda sivrisinek mi var olan?
 02 S *Ne*
 03 F Git elinne vuruver.
 04 S *Ooh. Fere mia pandofla*
 05 F Gı, elinne vur da, git elini yıkıver. (7'') Hiç sillogodan, hiç geçmiyon mu?
 06 S *An vrune kati, tha mu pun afti.*
 →07 F *Perna ke si pes kalimera, de hanis tipota, afto mu ipe ke o Ali., 'na lei' lei 'kalimera, otan ke me vlepi' lei 'a mu pi, a rti konda mu' lei 'na sizitisume'.*
 08 S *Pios to pe afto?*
 09 F *Aftos, to pedaki 'Thelo' lei 'Etsi na anihti' lei*
 10 S *Pu me xeri ma aftos?*
- 01 F Is this a mosquito over there?
 02 S *Yes*
 03 F Go and hit it with your hand.
 04 S *Ooh. Go get a slipper.*
 05 F Hit it with your hands, then go, wash your hands (7''). Don't you ever stop by the association?
 06 S *If they find out something, they will let me know.*
 →07 F *Just stop by and say "good morning". You have nothing to lose. This is what Ali told me.*
 08 S *Who said this?*
 09 F *Him, this guy, he says 'I want him to open up'.*
 10 S *How come that he knows me?*

Pattern III: Turn internal switching between languages so that no single language can be identified as the base language; keeping language choice open or the choice of a bilingual medium as part of the overall organization of talk (Meeuwis & Blommaert 1998, Auer 2000, Gafaranga 2007).

In example 5, an elderly female member of the community (FAM 1, city dwellers) constructs an extensive narrative contribution (turn 2) by means of the bilingual medium. In this excerpt, the alternation between languages has clear discourse functions. The direction of the switches is irrelevant, but the contiguous juxtaposition of languages contextualizes shifts in topic (a-1), the introduction/continuation of narrative (b- 2/4/8/12), evaluative comments (c- 3/6/7/11), reiteration for emphasis (d- 5/10), as well as different types of semantic contrasts (e- 9/11). The structure of the bilingual medium in this example is indicative of language choice patterns exhibited by older speakers who mostly alternate between codes to organize discourse. Every one of the switches in turn 2 (12 in total) has clear discourse functions. This is not always the case in the mixing modes exhibited by younger speakers (see example 6), which is a preliminary observation that calls for further research.

Example 5- FAM 1

01 S *Ti ekane aftos? Elia evale mesa.*

02 M *Şe ezmesi kodu galiba (.)* Dur bakalım ne kodu. (5') ((1-a)) *Pu les ke* ((2-b)) acık geçti arası kadının, kadıncık ölüverdi genç başınla. ((3-c)) *Pos lipithikame tote.* ((4-b)) Çocukları ufak ufak bıraktı. ((5-d)) *Mikra mikra ta fise orfana ta pedakia i gineka.* ((6-c)) Çocukların şeyini görmedi, mürvetini kadıncık. ((7-c)) *Lipithika para poli gi'afiti ti gineka yiati itan poli kali gineka.* ((8-b)) Sonra adam kaldı; Bedri. ((9-e)) *İtane ki' i siheromeni i mana tis, i yiayia tus.* ((10-d)) Anneanneleri çocukların. O kadın büyüttü o çocukları, ((11-e/c)) *me ton patera mazi. Kalos kakos.* ((12-b)) E sonra kadıncık yaşlıdı da, zaten daha çok yaşlandı sonra bu Selim'i artık, yengeleri mi oluyodu? Yengeleri oluyodu evlatlık aldı, Selma 'anım.

03 F *Ine, afti ine tis miteras tus adelfi ine.*

01 S *What did he do? He has put olives in it.*

02 M She seems to have used some pate (.). Let us see what she has stuffed it with. (5') ((1-a)) *You see* ((2-b)) after a short while, that poor woman died so young. ((3-c)) *How sorry we felt then.* ((4-b)) *She left her children ((and they were)) too young.* ((5-d)) The poor woman left the little children orphans. ((6-c)) The poor woman never saw her children's weddings. ((7-c)) *I was very sad about this woman because she was a very good woman.* ((8-b)) Then, he was left alone, Bedri. ((9-e)) *Her old mother, the children's grandmother was with them as well.* ((10-d)) The children's grandmother. That woman brought them up, ((11-e/c)) *together with the father. Somehow.* ((12-b)) And then, she was already an old woman, she grew older, then this Selim, wasn't she their aunt-in-law? Yes, she was, she adopted him, Selma. ((Selma adopted Selim))

03 F *She is, yes, she is their mother's sister.*

In example 6, the alternation between languages does not always serve discourse functions (Auer 2000). What is more, it is non-consequential on the level of language choice; instead, it results in an "open state of language choice" and can be seen as forming a continuum from discourse functional code-switching into a bilingual mode of interaction. Additionally, while switches by Mother (M) and Father (F) mostly pertain to Pattern IV intrasentential momentary switches that are not consequential for their choice of medium (turns 6, 8 & 11; also see example 3, turn 8), speakers of the children generation seem to have developed different ways of mixing and switching (Auer 2005: 406), that do not always serve the local organization of discourse. The continuous alternation of languages (24 in total, 20 of which done by the younger speakers of the group) mostly creates the effect of a single bilingual medium (Meeuwis and Blommaert 1998; Torras and Gafaranga 2002), which seem to be one of the preferred choices by younger speakers in their interaction with older community members.

Example 6- FAM 3

01 F: Ercan kuru kuru içilmez. Bi tane çatalla azcık yemek //

02 M: Yemek koyem.

03 FR: Aa.. istemiyom, istemiyom. Yidim ben.

- 04 M: Ne Yidin?
 05 FR: Evde *pitsa* yidim//
 06 M: *Pitsayı* kim yapıyo?=
 07 FR: =*Kafe ipia*.
 08 F: Len annem yemek yapmıyo mu? Oluyo mu böyle *pitsa bira, pitsa bira*?
 09 FR: *Ma ksero go! Şey, edo ke mia vdomada pitsa* yiyok.
 All: ((laughing))
 10 FR: *Ihame kolisi sto/ şey st'avga. Tora/ Yani, omeletala, hani şe oluyo/ Ohi omeleta/ Nası? İçine //*
 11 M: *Krepa* mı?
 12 FR: Hayır.
 13 D2: *Me lahanika?* Kabaklan?
 14 FR: *Lukaniko* gibi hani bişe.
 15 D2: *Sucuk?*
 16 FR: Ha *sucuk*
 17 D2: Eee, ondan mı?
 18 FR: Ondan. *Ihame kolisi safto. Kathe ke mia mera sucuk. E: leo, den pai allo, as alaksume.*
- 01 F: Ercan you cannot just drink. With a fork, some food//
 02 M: Shall I serve?
 03 FR: Ah, it's ok, it's ok. I have already eaten.
 04 M: What did you eat?
 05 FR: I ate *pizza* at home//
 06 M: Who made the *pizza*?=
 07 FR: =*I had coffee*.
 08 F: Hey, doesn't your mother cook? What is this *pizza beer, pizza beer*?
 09 FR: *See! Well, for a week now* we have been eating *pizza*.
 All: ((laughing))
 10 FR: *We were stuck/ well to the eegs. Now/ That is, with omelet, that is done/ Not omelet/ What do you call it? That inside ((you put something)) //*
 11 M: Was it *pancake*?
 12 FR: No.
 13 D2: *With vegetables?* With courgette?
 14 FR: Something that looks like *sausage*.
 15 D2: ((Turkish)) *sausage?*
 16 FR: Ya ((Turkish)) *sausage*.
 17 D2: E:, like this one?
 18 FR: Like this one. *We were stuck to that. Every single day ((Turkish)) sausage. E: I said, enough is enough, let us change.*

Pattern IV: Intrasentential momentary switches that do not change the language of the interaction. Participant related transfers (Auer 1995)/ the Medium Repair and the Medium Suspension Pattern (Torrás & Gafaranga 2002).

This is a code-alternation pattern that again raises the question of what counts as code/ medium as far as the language users are concerned. Contrasting cases, as momentary lapses of memory as to what a word is in the language of interaction, and systematic use of discourse markers or lexicon in the “other” language of the bilingual speaker have to be dealt with separately. The former has to do with either (lack of) competence or stylistics, whereas the latter with the potential of a single bilingual medium (Meeuwis and Blommaert 1998), as in the examples 3 (turn 8), 4 (turn 5), and 6 (turns 6, 8 and 11). The conditioning of Pattern IV alternations needs to be tackled both in terms of proportion and sentential structures, as well as in terms of textual structures and discourse functions, a discussion that exceeds the limits of the present study. What can be observed though, based on the examples that have been discussed so far, is that Pattern IV momentary switches that are placed within the boundaries of Turkish morphosyntactic structures are used by older speakers only, at least as far as our data are concerned.

6. Conclusions

Pattern I code-alternation within bilingual conversations has clear discourse functions. The languages of the speaker's repertoires are used to achieve "a contiguous juxtaposition of the semiotic systems" (Auer 1995), that contributes to the organization of discourse. It can be described as the *Discourse Oriented Pattern*. Patterns II, III & IV on the other hand, could be seen as more *Participant Oriented Cases* of code alternation. Pattern II, the negotiation over Medium Selection, is consequential for the overall organization of talk as it determines the medium of talk at least within the duration of a conversational episode. Pattern III is also consequential for the overall organization of talk as it seems to comprise the choice of a bilingual medium. Pattern IV alternations serve as momentary transfers from the medium of the interaction, as they do not alter the medium at least within the limits of a turn or an extended conversational episode. All four patterns often co-occur in longer conversational episodes, involving speakers of different orientations as to the politics of language as well as speakers of variable competences in the languages/ mediums of the interaction. Bilingual conversations seem to be moving along a continuum of prototypical code alternation, in which participants orient to a preference for one language-of-interaction and code-switch in order to organize discourse, towards code alternation of a less prototypical kind, i.e. the selection of a mixed code (Auer 1998, 2000) or a bilingual medium (Gafaranga 2007), in which locally operational discourse functions cannot always be identified (Georgalidou et al. 2010).

As far as the informal community organization and issues of identity are concerned, looking at the overall picture of the excerpts discussed, especially those of families 2 and 3 (FAM 2, FAM 3) in which younger members of the community exhibit their linguistic preferences, it becomes apparent that the alternating use of the community linguistic resources does not only serve discourse organization functions. There is a clear shift between *we* and *they* codes, as Greek and the Bilingual Medium are systematically used to construct youth identities, in contrast to the ones constructed by the adult members of close-knit community networks through consistent use of Turkish. Systematic use of Greek, as well as instances of code mixing, were also found in the discourse of adult speakers in the city networks, a fact that points to the shift towards a more extensive use of Greek in the more open community networks of the city⁴. Still, the generational distribution and the variable structures of Pattern III and IV code alternations are points in question that require further research.

TAMING – AND NAMING – THE GREEK “SUBJUNCTIVE”

Brian D. Joseph

The Ohio State University

joseph.1@osu.edu

1. Introduction

Linguists tend to want to approach a language on its own terms, so to speak, and find solutions for analytic problems by looking to the language itself. It cannot be denied that this is a valid and highly effective strategy; after all, the speakers of the language generally speaking do not have access to anything but their own language and the resources it provides for analytic decisions. Why then should linguists try to do anything different from that, especially if the goal of linguistic analysis is to develop an account of a language that mirrors native speakers' internalized knowledge, a “grammar”, of their language. Moreover, looking only to language-internal evidence for a particular analysis is certainly a reasonable first step for the analyst to take methodologically; bringing in external evidence, including outcomes of laboratory experiments or even insights from language games or poetic form, is a step that can come after the internal evidence has been assessed, as a type of corroboration for the internally arrived-at account.

Still, linguists also show a healthy interest in language typology and typological/structural comparison between and among different languages. Thus, for all the fact that linguists might like language-internal solutions, it is not at all unusual, and indeed, it is to be expected -- given that linguists do investigate languages on typological grounds -- that a problem in one language can be given illumination by a consideration of another language. Recognizing the value of language typology and typological/structural comparison between and among different languages is thus a suitable complementary approach to looking only to internal evidence.

The particular issue at hand that prompts these methodological musings is a thorny and troublesome problem in the analysis of Modern Greek for which some light from a comparative/typological perspective turns out to be useful.

2. The Problem

The problem in question is the verbal forms in Modern Greek that occur with *na* (and *as*, etc.) that have long been a locus of analytic controversy. The issues are well known, but some background is useful here. The analytic problem is that some of the specific verbal forms – and it is important to emphasize “forms” here since a key facet of the issue is how to deal with the distribution of the forms themselves, not their functions – that are found with *na* can occur independently, while others cannot. Thus, with imperfective aspect present tense forms, as (1a) and (1b) show, forms with or without *na* are possible as well-formed stand-alone utterances, whereas with perfective aspect present tense forms, as (1c) and (1d) show, only the combination with *na* gives an acceptable stand-alone utterance:

- | | | | | |
|-----|------------------------------|------------------------|---------------------|-------------------------|
| (1) | a. <i>na</i> γ rafo? | ‘Should I be writing?’ | b. γ rafo | ‘I write; I am writing’ |
| | c. <i>na</i> γ rapso? | ‘Should I write?’ | d. * γ rapso | ‘I write’ |

The analytical situation is complicated by the fact that the perfective forms also co-occur with other controlling elements such as WH-words, as in (2a-b), conditional markers, as in (2c), and some conjunctions, as in (2d), among others:

- | | | | | |
|-----|-------------------------------|---------------------|--------------------------------|-----------------------|
| (2) | a. <i>otan</i> γ rapso | ‘when I write, ...’ | b. <i>opjos</i> γ rapsi | ‘whoever writes, ...’ |
| | c. <i>an</i> γ rapso | ‘if I write, ...’ | d. <i>prin</i> γ rapso | ‘before I write, ...’ |

The generalization about the distribution of these forms therefore can be stated as in (3):

- (3) Modern Greek perfective present forms never stand alone; they must always be introduced by some “controlling” or “determining” element.

Virtually all descriptions and analyses of Greek make this observation, with many noting that there is one main exception to this generalization: the *fiji den fiji* construction, as in (4a), with perhaps also the fixed phrase *opu fiji fiji* as well, as in (6b):

- (4) a. *fiji den fiji* ‘whether he leaves or not’ (literally, “leaves/3SG.PERFVE not leaves/3SG.PERFVE”)
b. *opu fiji fiji* ‘run for your dear life!’ (literally: “wherever run/3SG.PERFVE, run/3SG.PERFVE”)

These are fairly isolated exceptions, with the lexicalized character of *opu fiji fiji* removing it from being much of an analytic concern; the *fiji den fiji* construction, however, does have some degree of productivity (cf. *bi den bi* ‘whether he enters or not’ and similarly constructed examples), and, as such, cannot be totally ignored.

So the facts are clear, but the problem lies in both analytic issues and a terminological one. On the analytic side, the questions are just what grammatical and especially morphological category this perfective present form represents and why it should be restricted as it is, being unable to stand alone and always requiring some supportive element that “selects” for it. On the terminological side, the question is just what to call this form and category.

For a language to have essentially a form that is always subordinated to some other form is not unusual at all from a typological standpoint. Cross-linguistically, this is in fact what is found with “subjunctive” forms in many well-known and well-studied languages, such as the Romance languages. As for the label, as Mackridge (1985: 174) observes: “The term ‘subjunctive’ ... suggests that the clause in which a subjunctive appears is subjoined (i.e. subordinated) to another”, and while he was talking about combinations such as *na yrapso* and not the form *yrapso* itself, the point is clear: “subjunctive” is appropriate if we are dealing with something that is always “subjoined”. This question of labeling therefore intersects with the question of whether Greek has a subjunctive mood, i.e. a verbal category associated with subordination.

Thus there is an analytic, as well as a terminological, dilemma here, in that if there is a category, it should be labeled. That is, we need not only to “tame” the subjunctive beast but also to “name” it.

3. So, Does Modern Greek Have a “Subjunctive”?

The issue is actually further complicated by another related fact. Given that *na* is a major player in the use of this form, though not the exclusive one, we can further ask, as many have – and this is perhaps where the analytic tangle arises -- whether *na* itself, or *na* as one of a set of determining markers, determines this “subjunctive”. As an alternative, one could say that the particular verb form, specifically the perfective present, is itself the reflection of the subjunctive category. These interrelated questions can be summed up as in (5):

- (5) The set of questions at issue here
a. is the combination of *na* (etc.) + Perfective Present (*na yrapso*) a “subjunctive”?, or ...
b. is the Perfective Present itself (*yrapso* alone) a “subjunctive”?, or ...
c. does *na* itself determine a “subjunctive”?, and in any case ...
d. what does “subjunctive” mean here?

In what follows, I stake out my position with regard to each of these questions and then address the analytic and terminological issues that arise from these positions. All are positions that are defensible in and of themselves, so that the combination of them poses a particular framework for addressing the overall issue in Greek morphosyntax of the nature of the *na* forms and the forms with *na*.

To answer (5d) first, I take the position here that “subjunctive” is to be understood only as a morpho-syntactic category, not a functional one; thus subjunctive-like uses are not the issue, though they turn out not to be totally irrelevant. As for (5a), my answer is yes, by virtue of the argument of Veloudis & Philippaki-Warbuton 1983 that the selection of negation marker can be correlated with mood: the negator *den* selects for and thus is an index of indicative mood whereas the negator *min* selects for and thus is an index of a subjunctive, the subjunctive being determined by the combination of verbal forms with *na* and *as*. The relevant distributional facts are shown in (6a-d); note that no matter what position one take on the distribution of the negators, it is simply a fact about Greek that

the imperative mood as such is idiosyncratically (for Modern Greek) not negatable, as shown in (6e), with the unambiguously imperatival form *elate* ‘come/IMPV.PL’.¹

- (6) a. $\text{den } \gamma\text{rafo} / \text{den } \epsilon\gamma\text{rapsa} / \text{den } \theta\alpha \gamma\text{rapso} / *_{\text{min}} \gamma\text{rafo} / *_{\text{min}} \epsilon\gamma\text{rapsa} / *_{\text{min}} \theta\alpha \gamma\text{rafo}$
 b. $\text{na min } \gamma\text{rafo} / \text{na min } \gamma\text{rapso} / \text{na min } \epsilon\gamma\text{rapsa} / *_{\text{min}} \theta\alpha \gamma\text{rapso} / *_{\theta\alpha} \text{min } \gamma\text{rapso}$
 c. $*_{\text{na}} \text{den } \gamma\text{rafo} / *_{\text{na}} \text{den } \gamma\text{rapso} / *_{\text{na}} \text{den } \epsilon\gamma\text{rapsa}$
 d. $\text{as min } \gamma\text{rafo} / \text{as min } \gamma\text{rapso} / \text{as min } \epsilon\gamma\text{rapsa} / *_{\text{as}} \text{den } \gamma\text{rafo} / *_{\text{as}} \text{den } \gamma\text{rapso}$
 e. $*_{\text{den}} \text{eláte} / *_{\text{min}} \text{elate}$ ‘don’t come’ vs. OK: *min erhete!* ‘NOT come/2PL.PRES.PRFVE’

The inability of imperative forms to cooccur with negation means that the fact that negative commands (prohibitions) are expressed with *min* plus a nonimperative form, as shown in (6e), cannot be used as an argument against taking *min* as correlating with subjunctive mood. In this account, *na* is essentially a marker of subjunctive mood and *min* is associated with subjunctive negation. Thus a prohibitive like *min yrapsis* in (6e) in this account must be analyzed as deriving from subjunctive used as a surrogate negative imperative, e.g. *na min yrapsis* ‘you should not write’. Accounting for *min yrapsis* this way would take advantage of the fact that *na* can sometimes be optional, as with *prin* ‘before’:

- (7) a. prin fijos ...
 before leave/2SG.PRES.PRFE
 ‘before you leave ...’
- b. prin na fijos ...
 na
 ‘before you leave ...’

There is, however, one undesirable aspect associated with deriving prohibitive *min yrapsis* from *na min yrapsis*: unlike the optionality of *na* with *prin* shown in (7), there is a difference in politeness and indirectness associated with the surrogate subjunctive prohibition that is not present with the simple prohibitive. That is, *na min yrapsis* is more polite and less direct as a negative command than *min yrapsis* is. It is not clear that simply allowing *na* to be optional in this case can achieve that effect. As it happens, the account advocated below in section 4 for categorizing forms like *yrapsis* can answer this issue without reference to mood categories and thus avoids the problem noted here; this is discussed in greater detail below.

Moving on to (5b), here I take the view that the perfective present is identical morphologically at least in terms of endings with all other (indicative) present forms; so the marking for Perfectivity would have to be the telling indicator, but it seems more to play an aspectual role, at least in all other instantiations. For instance, in the future, the difference between *tha yrapso* 'I will write' and *tha yrafo* 'I will be writing' is not a mood distinction; and, as (6a-b) show, it is negated with *den*, suggesting that it is indicative and not a bearer of subjunctive modality.

As for (5c), *na* can certainly be taken as a marker of subjunctive, but a possible complication that such a view entails is that *na* itself occurs with other tense/aspect forms, as shown in (8), with explanations of the combinations and their traditional name according to most grammars:²

- (8) a. *na ɛyɾafa* ‘I should have been writing’ (*na* + imperfective past tense (“imperfect”))
 b. *na ɛyɾapsa* ‘I should have written’ (*na* + perfective past tense (“aorist”))
 c. *na ixa yɾapsi* ‘I should have written’ (*na* + perfect past tense (“pluperfect”))

The complication here is that under this view, Greek would have not only a *present* subjunctive but also a *past* subjunctive, a *pluperfect* subjunctive, etc. Admittedly, this may not be a serious problem but it does multiply categories simply to sustain the analysis by which *na* is a marker of subjunctive mood. The converse is also problematic: if *na* determines a subjunctive by virtue of combining with the perfective present, what is the status of the other elements that combine with that form, such as *otan* or *an*, seen in (2); here perhaps the position of Barri 1981 is relevant, as he opts for a broader view of what subjunctives can be, via a set of “converters” -- including *otan*, *an*, and *na*, among others -- that select for the Perfective Present. The issue there is that it reduces the matter to a list with no reason for inclusion on the list and no reason even for the existence of such a “list” whose elements have such properties.

¹ I use *elate* here because some imperative forms in the plural are identical to the perfective present form, e.g. *fijete* 'leave/PL'; singular forms are similarly unambiguous and could be used here to make the same point, e.g. neither **den kane* nor **min kane* are possible for 'don't do!'. with the singular imperative *kane* 'do!'.

² See Agouraki 1991 for a review of possible positions on status of *na*.

Thus, no matter how one treats *na* vis-à-vis the subjunctive, problems arise. If *na* is taken to determine the subjunctive, then the forms in (2) would not be subjunctives -- and note that they are negated with *den* (e.g. *an den yrapso* ‘if I don’t write’),³ even though indefinites, as in (2b), and conditionals, as in (2c), are domains where “subjunctive” mood might be expected on cross-linguistic grounds. If, instead, forms like *yrapso* alone determine subjunctive mood, then one has to question what the function of *na* is in (1a) and what the status of the imperfective form in (1a) is; is *na* a complementizer, a subordinating conjunction, or the like, despite its prosodic weakness, i.e. the fact that it never occurs alone and is always unaccented?⁴ Thus, some solutions have focused on particular combinations, making this more a syntactic issue, as with Veloudis and Philippaki-Warbuton 1983, while others, e.g. Barri 1981, have emphasized the role of selection by certain elements, with *na* simply being one of a set, not necessarily a natural class of elements.

4. Light from Hibernia

As suggested in section 1, taking a cross-linguistic view on a problem, especially when the language-internal resources for a solution are exhausted, can be fruitful. I suggest that taming and naming the Greek subjunctive is just such a case. In particular, while I am sympathetic to solutions such as those discussed in section 3, this seems to be a case where we can gain some insight by focusing on the verb *form* itself rather than the elements that combine with it, and then looking to other languages with similarly restricted forms. One especially attractive parallel is to be found in some of the Celtic languages, Welsh and Irish being the best examples.

In particular, in Old Irish (as also in modern Irish and Welsh, but most clearly instantiated in Old Irish), one finds a distinction in verb forms known as “*absolute*” versus “*conjunct*” for simple verbs, i.e. verbs that consist essentially just of the verbal root, and a related distinction known as “*prototonic*” versus “*deuterotonic*” for compound verbs, i.e. verbs that consist of the verbal root augmented with prefixes, which are often called prepositions but can also be referred to as preverbs. This somewhat complicated situation in Old Irish is described as follows in Thurneysen (1946: §542):

In most tenses and moods the person endings have two form, to which the names ‘conjunct’ and ‘absolute’ have been given The conjunct flexion occurs:

1. In all verbal forms compounded with prepositions
2. In simple verbs:
 - (a) after the verbal particles *ro* [marking perfectivity] and *no* [marking certain past tenses];
 - (b) after the conjunctions and particles listed in § 38, 2 under the name of conjunct particles;
 - (c) in the archaic examples where the verb stands at the end of its clause.

The absolute flexion is confined to simple verbs in positions other than the above-mentioned. It alone has relative forms with special endings (§ 566 f.).

Some examples of these forms, showing the differences between absolute and conjunct, are given in (9):

(9)	<i>Absolute:</i>	berid	‘he bears’	<i>Conjunct:</i>	do · beir	‘he brings’
		mórmair	‘we magnify’		ní móram	‘we do not magnify’
		léicit	‘they leave’		co lécet	‘how do they leave?’

As noted above, the distinction between “*deuterotonic*” and “*prototonic*” forms is similar; the terminology refers to the placement of stress in the string of elements making up compound verbs (preverbs plus verbal root), whether it is on the second element in the string (e.g. *beir* and *tibi* in the examples in (10)) or on the first element in that string (e.g. *as* and *con* in the examples in (10)),⁵ but the distribution is just like the absolute/conjunct distinction, as shown in (10):

³ In high-style writings in the archaizing variety *katharevousa* (now largely abandoned but widely used into the mid-to-late 20th century in academic and legalistic contexts), clauses with *an* ‘if’ were negated with *min*, e.g. *an mi sfaló* ‘if I am not mistaken’.

⁴ I draw a distinction between this (subordinating) *na* and the deictic presentational predicate *ná* (always accented) ‘here!’; see Joseph 1981 for discussion.

⁵ There are phonological changes in the preverbs and root associated with being stressed or not; those are irrelevant here but they account for the difference between, e.g., *as* and *e* or *beir* and *pir* in (10). The underlying forms given in (10) are meant just as

(10)	<i>Deuterotonic</i>	as · beir ‘says (stress: as · <u>beir</u>)	<i>Prototonic</i>	ní · epir ‘he does not say’ (stress: ní · <u>epir</u> (= /ní- <u>as</u> -ber/)
		con · tibi ‘mocks (stress: con · <u>tibi</u>)		ní · cuitbi ‘he does not mock’ (stress: ní · <u>cuib</u> i (= /ní- <u>con</u> -tib/)

Importantly for Greek, the conjunct and prototonic forms occur only when there is some supporting/governing element, and they do not stand alone, thus paralleling the restriction on the Greek perfective present forms exactly.

Furthermore, it is not just the use of verb forms in Old Irish that parallels the Greek situation, but there is also a set of so-called “conjunct particles” that must be given attention, for these are particles that require the conjunct and prototonic forms; these include such elements as the negative *ní*, the conditional/concessive *cia* ‘although; even if’, combinations of prepositions fused with the relative pronoun (e.g. *cosa* ‘with whom’), and the interrogative marker *in*, among several others.

Moreover, just as with the few cases (one productive and one unproductive) like *fiji den fiji* where there is no governing particle, so too does that happen occasionally in Old Irish with conjunct and prototonic forms. A somewhat productive use of these otherwise bound forms comes in the so-called “responsive” form, which is a verb form repeated from a question to signal an affirmative response, e.g. *Ní-chumci sòn* ‘Thou canst not (do) that’ ... *Cumcin écin* ‘(Yes), I can indeed!’, where *cumcin* is a dependent form, here prototonic. A more restricted usage is the phenomenon known as Bergin’s Law, described by Thurneysen §513b as follows: “Simple and compound verbs may be placed at the end of their clause; the former then have conjunct flexion (§ 542), the latter prototonic forms”. This is an “archaic feature” by Thurneysen’s reckoning, found, as he says, only “in Irish poetry and in non-metrical ‘rhetorical’ prose”.

I propose, therefore, as solution to the problem of the Modern Greek subjunctive and the behavior of the perfective present forms, that we need to recognize the relevance for Greek of an Irish-like distinction between absolute and conjunct forms. That is, we can extend the value of the traditional Irish distinction outside of Celtic and categorize *yrapsō* as a “conjunct” form. This move has the direct benefit of recognizing overtly this form’s restricted distribution and explains why it is found only with some “supporting” element, i.e. why it cannot stand alone.

This is rather like Barri’s approach, but it focuses on the verb form rather than on the elements that combine with it, though a set of “conjunct particles” for Greek would need to be identified. Interestingly, there is considerable overlap between the types of items that would be on the Greek list and those in the Old Irish set, in that in the respective lists of both languages, there is a negator (Irish *ní*, Greek *min*), a conditional element (Irish *cia*, Greek *an*), and relative-like forms (Irish *cosa* and other prepositional relatives, Greek indefinites like *ópjos* with their similarity to (historically) related relatives such as (*o*) *opíos*), among some others.

Furthermore, this approach solves the dilemma raised by the prohibitive construction of the type *min yrapsis*, discussed above in section 3. In this account, *min* simply becomes one of the conjunct particles, joining *otan* and *opjos* and others, and there is no need to associate it with the more polite negative command introduced by *na*; in that way, no account is needed of the absence of *na* in *min yrapsis* or the difference in politeness between the two forms of negative commands (*na min yrapsis* and *min yrapsis*). It is admittedly an idiosyncratic, and thus unexplained, fact that *min* is used in this way and selects for the conjunct form, but in a sense that is no more idiosyncratic than the fact that imperative forms cannot be negated in Modern Greek; they were negatable in Ancient Greek, for instance.⁶

Moreover, in this approach, there is the side benefit of showing how linguistic typology, in the form of information on an issue in one language can offer illumination on a difficult problem in the analysis of another language. It does mean recognizing absolute/conjunct as a relevant morphological distinction for Greek, but it is one that is needed independently for Irish and Welsh, and thus in a sense is “available” in the universal inventory of categories.

rough indicators of the morphemic make-up of the forms in question and not as a thoroughly worked out analysis of Old Irish morphophonology.

⁶ This account, admittedly, requires that the *min* of *na min yrapsis* and the *min* of *min yrapsis* need to be treated as different, though possibly related, elements. Janda and Joseph 1999, though, have argued for just that position, claiming that these two instantiations of the form *min* are to be separated from one another, even though allied in some ways as part of a morphological “constellation”.

5. Some Drawbacks

The solution proposed here is not without some drawbacks. For instance, the categorization of perfective present forms as “conjunct” does not really explain the facts, but rather puts them in a context where they become understandable; that is, with this labelling, assuming it has some cross-linguistic significance, the Greek form can be aligned with the behavior of “conjunct” forms in general, cross-linguistically. The question of why conjunct forms behave this way is a different analytic issue that cannot be addressed here but must remain a question for further research.

Moreover, the parallel between Greek and Irish proposed here is not exact. The Greek verb forms are not different from ones that occur as “absolute” forms, yet in Irish, the conjunct and absolute forms do differ. Also, Greek has verbs that are compounded with preverbs, as does Irish, some of them even cognate (e.g. Greek *pro* and Irish *ro*), but the behavior of preverbs is very different in the two languages; preverbs in Greek do not select for a conjunct verb form in the way that preverbs in Irish trigger the occurrence of conjunct forms..

Still, what I suggest is compelling about this proposal are three key aspects of it. First, it focuses on the form, not on the function to which the form is put, and in that way offers a basis for the clarity that the concreteness of actual forms and their distribution affords, as opposed to the abstractness sometimes encountered when one tries to categorize various functions as same or different. Second, the Celtic distinction has some of the same quirks that the Greek situation does, in that there are forms that always co-occur with an odd assortment of items that are not really characterizable as a natural class. Finally, there are even a few more or less isolated exceptions to reckon with in each language. For these reasons, I submit, extending the Celtic absolute/conjunct distinction to Greek provides a basis for both taming and naming the Greek subjunctive.⁷

⁷ There is a final argument for this proposal that involves a somewhat lighthearted appeal to authority. Such an appeal is not always the best sort of argument but it is perhaps worth mentioning here in a footnote, and thus as a secondary source of support. This is especially so since an appeal to this authority is one that is hard to ignore in the Greek context. The scholar who coined the terms “absolute” and “conjunct” for Old Irish was the 19th century German scholar who was the founder of Celtic philology, Johann Kasper Zeuss. While his name was pronounced [zojs], if it is Hellenized, to Ζεϋς, then we can see that we must take it seriously: how many of us can say that a solution we offer to an analytic problem is truly something διόσδοτον!

THE REALISATION OF VOICELESS GREEK VOWELS

Marianna Kaimaki

University of York, UK

marianna.kaimaki@york.ac.uk

ABSTRACT

Previous studies of the acoustic properties of Greek vowels have indicated that they may be voiceless in certain phonological contexts. Researchers (e.g. Dauer, R. M. 1980, Mennen & Okalidou 2006) have suggested that devoicing is restricted to the high vowels /i/ and /u/. I propose that the whole range of vowels can be produced voiceless in the appropriate phonological environment which is utterance-finally after voiceless consonants, under two conditions: (1) the vowel must be unstressed and (2) the intonation contour associated with the word in which the vowel occurs must fall (utterance-final voiceless vowels do not co-occur with rising contours).

1. Introduction

Linguistic studies on the interface of Phonetics/Phonology regarding the acoustic characteristics of Greek vowels are limited and based on data from read speech (see also Nikolaidis 2002, 2003 who investigated spontaneous speech data). Despite the fact that vowels are voiced by nature, some studies report that under certain phonological circumstances (e.g. in an unstressed position) some vowels get lenited or lose some of their characteristics (e.g. from peripheral they become central (Baltazani 2007)). Research so far (e.g. Dauer, R. M. 1980, Charalambopoulos, Alvanoudi, Didaskalou, Lambropoulou, & Poulli, 2003, Mennen & Okalidou 2006) suggests that the vowels which undergo lenition or deletion are /i/ and /u/. We propose that the process of lenition or deletion is not limited to high vowels but that in certain phonological environments all Greek vowels may undergo changes in their distinctive characteristics and more specifically their voicing. Determining the validity of this hypothesis is of linguistic interest as voiceless vowels are typologically rare and are not always implicated with the kind of morphological functions mentioned above. The results of the study then are anticipated to contribute to both understanding the nature of Greek vowels as well as understanding the typology of natural languages.

Preliminary research conducted by the author revealed that voiceless vowels can occur in utterance final position. This phenomenon merits attention as reports of voiceless vowels are rare and usually found in non-Indo-European languages like Japanese (Tsuchida 2001; Vance 2008), South Paiute (Harms 1966) and Comanche (Canonge 1957) as well as in Finno-Ungarian languages like Finnish (Ogden 2001). Pilot research conducted on recorded dialogues which were collected for the purpose of the completion of the author's PhD thesis confirmed the findings reported to date but also revealed some new interesting facts. It was noticed that the same rule that applies for the high vowels /i/ and /u/ can be applied on any of the vowels of Greek (/i, e, a, o, u/) under the following conditions:

- a) the vowel to be utterance final
- b) the utterance to have a final falling pitch and
- c) the consonant to be voiceless.

This finding opens up a series of important questions regarding the realisation of Greek vowels. In this paper I will examine:

- the distribution of voiceless and voiced vowels with relation to the vowel quality and intonation (falling/rising)
- whether the phenomenon of all utterance-final vowels (a, e, i, o, u) being realised as voiceless is a phonetic process which may vary potentially depending on the vowel quality or whether it is a phonological rule with wide distribution and specific locus of application.
- whether the realisation of voiceless vowels is related to the idiolect of the speaker or whether it reflects a wider rule of the language which has not been noticed so far.

As Greek is a language with rich morphophonology at the right end of the word, the possibility of voiceless final vowels not being perceived by listeners is very important as it may lead to misinterpretation of the linguistic message. For example, it could lead to the loss of distinction between the first and third person in the verbal forms of 'έχασα' and 'έχασε'. The findings of this research, then will have important applications in the perception/processing of messages in new technologies (e.g. recorded telephone messages) as well as in developing specialised (oral) materials for teaching Greek.

2. Material and methods

12 native speakers of Greek (6 males and 6 females with ages ranging from 20 to 65) as spoken in the city of Thessaloniki produced utterances which included words containing the vowels /i, e, a, o, u/ in unstressed final positions. The stress pattern as well as the number of syllables and the quality of immediately preceding consonants were controlled for in the stimuli but syllable complexity in the middle or beginning of the word was not considered at this stage. I varied the phonological environment for every vowel so as to cover the variety of Greek consonants. Table 1 shows the experimental data used.

TARGET V	PHONOLOGICAL CONTEXT						
	PLOSIVES		FRICATIVES				
	c, k	p	t	f	θ	s	ς, x
i	'evɛfi άβαφι unpainted	'kenɔsi κένωση void	'ɛsiti άσιτη ungrained	'psɛftiki ψεύτικη fake	'ɛnɔhi ένοχη guilty	'ɛfipi έφιππη on horseback	'ɛvɛθi άβαθη shallow

TOTAL	35						

Table 1 Target words

Participants produced these words in 2 carrier sentences controlling for rising and falling pitch; the two carrier sentences used were:

1. Πώς σου είπε η Μαριάννα πως γράφεται το _____ ;

How did Marianna tell you _____ is spelt?

2. Η Μαριάννα μου είπε να πω _____ .

Marianna told me to say _____ .

Carrier sentence 1 was produced once for each phonological context + target vowel giving out 35 stimuli. Carrier sentence 2 was produced twice for each phonological context + target vowel giving out 70 stimuli. The data was randomised (5 randomisations) to avoid any effects that might be brought forward by the order of the stimuli. Each speaker produced 105 target sentences in total plus 114 dummies.

The acoustic characteristics of the vowels were examined (duration, spectral characteristics and pitch characteristics) for all productions in order to determine their phonetic realisation. Finally, I ran regression analysis on the results in order to determine the statistical significance of the results.

3. Results/Discussion

There was considerable variability in the phonetic realisation of final vowels with falling and rising pitch. Final vowels of sentences with final falling intonation were produced as: 1) fully voiced, 2) voiceless, 3) creaky and 4) breathy while final vowels of sentences with final rising intonation were produced as 1) fully voiced, 2) creaky and 3) breathy.

Figures 1 to 8 show spectrograms and waveforms associated with the final syllables of the target words illustrating the phonetic variability encountered in the data. Figures 1 and 2 show examples of fully voiced final vowels produced with final falling (Figure 1) and final rising (Figure 2) intonation. In both figures we can see high energy in the first two formants (F1, F2) and regular glottal pulses in the spectrogram and waveform.

Figure 1 Voiced final falling CV

Figure 2 Voiced, final rising CV

Figures 3 and 4 show examples final creaky vowels produced with both falling and rising intonation. In both figures we can see the energy in F1 and F2 fading in and out and the glottal pulses being irregular.

Figure 3 Creaky, final falling CV

Figure 4 Creaky, final rising CV

Figures 5 and 6 show cases of final vowels produced with breathy voice. We can see there is regular vocal fold vibration which is accompanied by frication giving out the percept of breathy voice.

Figure 5 Breathy, final falling CV

Figure 6 Breathy, final rising CV

Figures 7 and 8 show two examples of final voiceless vowels. In both cases we can see that there is no voice bar associated with the vowels. In figure 7 we can see the onset of the voiceless vowel right after the release of the plosive. There is some energy at the low frequencies but there is no regular vocal fold vibration associated with the vowel.

Figure 7 Voiceless V

Figure 8 Voiceless V

In figure 8, we can see a high close voiceless vowel, which is produced right after the production of a voiceless palatal fricative. We can see that there is no voicing associated with the vowel but there is more energy concentration in the higher frequencies than for the fricative preceding the vowel.

From the examples presented so far we can see that there is considerable variability in the production of final vowels in terms of their acoustic features. The variability does not **depend** on the prosodic design of the carrier sentence for the fully voiced, breathy and creaky productions of final vowels. The voiceless cases of final vowels though only occur in carrier sentences with final falling intonation, which means that there is an association between final falling intonation and the realisation of vowels as voiceless. This constraint is particularly interesting as one of the reviewers pointed out voiced obstruents are usually associated with low pitch (Bradshaw 1999). Possible explanations for this constraint are examined in section 4.

Figure 9 Voice quality of final rising vowels

Figure 9 shows a bar chart showing the distribution of voice quality associated with each kind of final vowel produced with a final rising intonation. As we can see there are no instances of voiceless tokens. /a, e, i, o/ have similar distributions with most their instances being produced fully voiced, with regular vocal fold vibration; creaky voiced instances of final vowels follow in number and there are also some small numbers of breathy voiced instances. Note that /u/ is never found produced with breathy voice in any of the final rising carrier sentences.

Figure 10 Voice quality of final falling vowels

Figure 10 shows a very different picture in terms of distribution of voice quality which is associated with final vowels produced in final falling carrier sentences. We can distinguish two groups in terms of voice quality distribution; /a, e, i/ and /o, u/. /a, e, i/ all have breathy manifestations for the majority of their productions. Creaky voiced instances of /a, e, i/ are also a big part of the data followed by voiced and voiceless instances. /o, u/ have a very different distribution from /a, e, i/ and partly from one another but the distribution is similar in that the majority of their productions are voiced or creaky with the numbers almost reversed for /o/ and /u/ (more creaky for /o/ more voiced for /u/), and number of instances for breathy and voiceless manifestations are similar but reversed (more breathy than voiceless cases for /o/ and more voiceless than breathy cases for /u/). What is important to note is the fact that the whole set of vowels /a, e, i, o, u/ have voiceless instances and not just the high vowels.

Figure 11 Number of voiceless vowels

The number of voiceless vowels encountered in the data and their distribution as to vowel quality is shown in figure 11. From the bar chart we can see that /i/ and /u/ have the highest number of voiceless instances which agrees with research done so far. It is also clear from the chart though that open and mid vowels have some of their instances produced with no vocal fold vibration as well. In order to check whether there is any relation between the realisation of a vowel as voiceless and its phonological environment a bar chart (figure 12) was created that shows the breakdown of voiceless vowels to preceding consonants.

Figure 12 Vowels with individual consonants

From figure 12 we can see that all kinds of consonantal environments examined allow voiceless vowels following them. Overall, the total numbers of voiceless vowels are similar amongst consonants ($p=5$, $t=10$, $k=12$, $f=10$, $th=12$, $s=15$, $h=8$). The manner of articulation of the consonants though seems to play a role in the number of instances of voiceless vowels that occur after a consonant, as there are more voiceless vowels after fricatives ($N=45$) than plosives ($N=27$). Despite fricatives having more voiceless vowels occurring after them, not all fricatives have voiceless instances of the whole set of vowels; only after /s/ all vowels (/a e i o u/) were produced as voiceless. From the data examined so far there is no particular pattern as to the vowel quality of voiceless vowel and the place of articulation of the consonant.

Figure 13 Breakdown of voiceless vowels to speakers

Figure 13 shows a bar chart with the breakdown of voiceless vowels to speakers. As the bar chart shows 9 out of 12 speakers produced voiceless vowels. In terms of sex, more males (n=6) produced voiceless vowels than females (n=3) but individual females produced more voiceless vowels than individual males.

Figure 14 Voiceless vowel distribution in individual speakers

Figure 14 shows a bar chart showing the distribution of voiceless vowels to individual speakers. L (female) and PK (male) are the only speakers who have the whole set produced as voiceless and they are the ones who produce the most voiceless vowels (L=24, PK=15). From the rest of the speakers who do not have the whole set, we can see that there is a pattern as to which vowels they produce voiceless first and which vowels follow. The high close vowels /i, u/ are the first that speakers produce voiceless and only if they have voiceless instances of those vowels do they then extend to the mid and open vowels.

Summary

From the results reported so far we conclude that final rising utterances do not display much variability in the voice quality of the final vowels and they do not display any final voiceless vowels. Final falling utterances on the other hand display considerable variability in the voice quality of final vowels and they display the whole range of voiceless vowels with /i/ and /u/ being the first to get produced voiceless.

Regression analysis was performed to determine whether there is any statistical significance for the results reported. Analysis showed a significant relationship between height and closeness of the vowel and voicelessness [for /i/, $p=0.017$, for /u/, $p=0.0017$] which suggests that the presence of /i/ and /u/ increased the possibility of the vowel of a final falling utterance being produced with no voicing.

Results also showed that voiceless vowels are more likely to appear after voiceless fricatives rather than voiceless plosives and that the distribution of voiceless vowels was not even across all speakers. In terms of usage by sex, more males used voiceless vowels than females but individual females used them more than individual males.

4. Conclusions and perspectives

In this paper we extended the existing research on the production of Greek vowels. Unlike findings reported by research so far, our results showed that all Greek vowels (/a, e, i, o, u/) can be realised as voiceless. Results also showed that there is variability in the realisation of final falling Greek vowels in our data for both rising and falling conditions but the nature of variability is not the same in the two cases. In this section we will endeavour to give an account for this phenomenon and assess the implications for the phonology of the language.

Final vowels in our data were produced with either final falling or rising pitch and their acoustic characteristics varied accordingly. Final vowels produced with falling intonation were found to have four distinct phonetic qualities: 1) fully voiced, 2) voiceless, 3) creaky and 4) breathy. There are at least two potential interpretations for the variability encountered. We can try to account for this variability with reference to the physiology of the vocal tract and the articulatory mechanisms for producing speech. Following this train of thought we could start making claims about how it is not surprising that falling pitch, which is accomplished by slow rate of vocal fold vibration, is accompanied by creaky voice or breathy voice or voicelessness as this could be natural physiological consequence of the vocal folds vibrating slowly or even to stop vibrating altogether. However, our data also showed that final vowels produced with rising intonation were found to have three of those distinct phonetic qualities: 1) fully voiced, 2) creaky and 3) breathy. In this case it would not be possible to try and account for it using a physiological explanation as rising pitch is accomplished by increasing the rate of vocal fold vibrations which would make it harder to explain how we find breathy and creaky voice quality associated with rising pitch. The second possible interpretation would be to account for it phonologically. Following this interpretation we would have two phonological statements; one for rising and one for falling pitch:

1. If a vowel is associated with final falling intonation the range of variability for its production is: fully voiced, creaky, voiceless, breathy.
2. If a vowel is associated with final rising intonation the range of variability for its production is: fully voiced, creaky, breathy.

From the results reported so far we also concluded that final falling utterances display the whole range of voiceless vowels with /i/ and /u/ being the first to get produced voiceless which agrees with the outcome of the regression analysis which showed that there is a significant relationship between height and closeness of the vowel and voicelessness. This result is of considerable importance as it complements research done on the Greek vowels so far by providing new evidence for the presence of voiceless vowels in Greek. One account explaining this phenomenon is that this is a phonetic process which may vary potentially depending on the vowel quality. However, as all vowels can be produced voiceless this cannot be a sufficient explanation for the data. Another hypothesis could be that this is a phonological rule with wide distribution and specific locus of application. The current experiment does not provide us with all the required data that would allow us to make such a generalisation. From the experiment it is clear though that all voiceless consonants seem to allow this process with one condition; the utterance has to have a final falling intonation. Results also showed that voiceless vowels are more likely to appear after voiceless fricatives rather than voiceless plosives which indicates that the phonological context may be an important factor in determining the realisation of the final vowels as voiced or voiceless.

As the experiment involved different individuals and the distribution of voiceless vowels was not even across all speakers, there is also the issue whether the realisation of voiceless vowels is related to

the idiolect of the speaker. In terms of sex, more males used voiceless vowels than females but individual females used them with greater frequency than individual males. In order to determine whether this phenomenon reflects a wider rule of the language, more data (maybe of a different kind) is needed. One reviewer suggested the possibility of the presence of voiceless vowels being a dialectal effect. However, as I mentioned in section 2 all subjects were speakers of the Urban variety of Greek as spoken in Thessaloniki which does not exhibit vowel lenition processes found in Greek northern dialects.

The results of this experiment are of particular importance as final Greek vowels may carry morphosyntactic information. A production of a voiceless vowel, may result in the neutralisation of contrast between e.g. *egrafa* and *egrafe* leading to loss of morphosyntactic information. If the vowels are realised as voiceless but the linguistic message is still perceived nevertheless, then there should be some other factor contributing in the decoding of information. This could be intonation, traces of spectral information of the vowel in the preceding consonant or the overall context.

THE ACOUSTICS OF POST-NASAL STOP VOICING IN STANDARD MODERN GREEK

Evia Kainada

Technological Educational Institute of Patras

ekainada@teipat.gr

ABSTRACT

This paper reports on a production and a perception experiment investigating post-nasal stop voicing in Greek with two goals: (i) to establish whether the process is categorical, and (ii) to identify the type of effect exercised by prosodic boundary strength on it. It is shown that the phenomenon is categorical, and is influenced categorically by boundary strength (it only occurs within the lowest domain of the prosodic structure). Variation is evident across lexical items, whereby some items undergo voicing more frequently than others. Experimental results are also presented on the acoustics of voiceless and voiced stops of Standard Modern Greek; voiceless stops have shorter closure duration, longer release duration and smaller amplitude within the closure and the release than voiced stops.

1. Introduction

Sandhi phenomena of Standard Modern Greek have gained a substantial amount of interest over the last years, as shown by several impressionistic and acoustic analyses investigating their application (e.g. for acoustic analyses Pelekanou and Arvaniti 2001, Baltazani 2006, Baltazani 2007, Kainada 2007, in press, Tserdanelis 2004, and for impressionistic analyses, Nespor and Vogel 1986, Condoravdi 1990, among many other studies in the area). Research interest on sandhi phenomena is mainly derived from the need to understand two different sides of their nature; first, their acoustic manifestation, and second the regulating factors of their application. This paper addresses both issues; using a perception and a production experiment it examines the acoustics of SV in Greek, compares it to those of voiceless and voiced stops, and investigates prosodic boundary strength effects on its application.

Results show that SV applies categorically, i.e. its acoustic manifestation is clearly divided in voiceless and voiced instances. Perceptually, SV is a very prominent process, since speakers of SMG classify voiceless vs. voiced instances with distinctive ease and high inter-rater agreement. Acoustically, SV instances are similar to those of voiced stops of SMG. Finally, results show that the prosodic structure exercises a categorical effect on SV application in that it is only allowed within the lowest post-lexical domain of the structure, while within that domain the phenomenon is optional and varies in frequency across different lexical items. Importantly, this paper compares, for the first time to my knowledge, the acoustics of voiceless and voiced stops in SMG.

1.1 Phonology and phonetics of post-nasal stop voicing

SV is a process whereby a voiceless stop assimilates in voice to the preceding nasal, as in example (1) from Modern Greek.

(1) τον πατέρα /ton pa'tera/ 'the father' → [toba'tera]¹

This is a phenomenon that has been attested in many languages, such as Modern Greek (Newton 1972), Japanese (Ito & Mester 1986) and others (see Hayes & Stivers 2000). In Modern Greek, the

¹ There is a question as to whether the voiced stop is preceded by a nasal, if the nasal is deleted or if it is retained as prenasalisation. This is not part of the current investigation (but see Arvaniti and Joseph 2000). In the example shown here the nasal is deleted.

phenomenon can be found both lexically and post-lexically. Lexically, it is obligatory and can appear word-initially or word-medially, e.g. ντάμα ('checkers') (which can be produced as either [ˈdama] or [ˈⁿdama], whereby prenasalisation is optional and is influenced by social factors and style, e.g. Arvaniti and Joseph 2004). Post-lexically voicing is optional, and again speakers have the option of prenasalisation (Arvaniti 1999). The present paper only deals with *post-lexical post-nasal stop voicing*.

The phonological/prosodic conditions that allow for the application of SV post-lexically are not clear. Nespor and Vogel (1986) proposed that prosodic structure regulates SV, in the sense that it will occur within a clitic group (henceforth CG), but will be blocked across CGs. In a somewhat circular reasoning, the authors proposed the existence of the CG as a domain of the prosodic hierarchy, on the basis that SV is disallowed across two of those domains. According to this analysis, SV is obligatory within prosodic words, optional within the clitic group, and is blocked across clitic groups ([–cont] → [+voice] / [...[...[+nas]]ω[____]ω[...].]C). Examples (2a) and (2b) (Nespor and Vogel 1986:158-9) show two constructions, whereby in (2a) voicing is allowed, while in (2b) blocked the reason being, according to the authors, that the two words in 2a belong in the same CG, while the two words in 2b are two CGs.

(2a) δεν πειράζει → [ðembi'razi]

(2b) όταν πας → *[ˈotambas]

Malikouti-Drachman and Drachman (1988), on the other hand, refute that SV depends on prosodic constituency and propose that the distribution of its application can be analysed on the basis of syllabification. According to their analysis, SV takes place when the preceding nasal is syllabified with the onset of the syllable containing the stop, while when it is placed as the coda of the preceding syllable SV is not allowed.

Additionally to the above conflicting approaches, there is one overall point of criticism that has emerged in recent research regarding the treatment of sandhi phenomena. It has been shown that not all sandhi phenomena have a categorical outcome, as one would expect from their phonological description (e.g. Arvaniti 2007). For example, an acoustic analysis by Zsiga (1997) showed that vowel hiatus in Igbo is not resolved categorically via complete assimilation, as traditional phonological analyses would have it, but rather has a gradient output. Similarly, Pelekanou and Arvaniti (2001) and Baltazani (2007) have shown that /s/-voicing in SMG is a gradient process while Baltazani (2006) and Kainada (2007, and in press) have shown that vowel hiatus resolution is also a gradient process in SMG. All the above clearly showcase the need to link phonological analyses to acoustic studies, at least in the case of sandhi phenomena. The present paper aims at filling a gap in research by examining the acoustics of SV in SMG, specifically by testing whether SV applies categorically or gradiently and how boundary strength affects its application.

1.2 Phonology and phonetics of voiceless and voiced stops of SMG

Phonologically speaking, Modern Greek employs voiceless and voiced stops (Mirambel 1961, Mackridge 1985, Philippaki-Warbuton 1992, Arvaniti 2007). Voiceless stops are unaspirated (Fourakis 1986b, Botinis, Fourakis & Prinou 1999, Arvaniti 2001, Nicolaidis 2002); voiced stops are fully voiced, i.e. voicing appears well before the burst and continues throughout the closure. While past research has examined the durational characteristics of voiceless stops in Greek (Fourakis 1986a, Arvaniti 2001, Nicolaidis 2001, Nicolaidis 2002) we are lacking studies examining the acoustic characteristics of voiced stops. In a recent study looking at the acquisition of voiced stops by greek children, Kong, Beckman and Edwards (2007) reported that durational and amplitude differences can distinguish between the two categories, but this was based on a single adult speaker². Botinis et al. (1999) showed that closure duration was longer in voiced than voiceless stops and that VOT was longer in voiceless than voiced stops (see also Antoniou et al. (2011) regarding VOT as produced by bilingual speakers). In what follows, the acoustics of voiceless and voiced stops in SMG will be presented and compared, since the two categories will act as baselines against which SV instances are compared in Experiment 2 (§3.2.3).

² Panagopoulos (1974) also investigated voiced stops, but the presentation and methodology used for the acoustic and articulatory measurements makes it somewhat difficult to compare to current experimental acoustic analyses.

2. Experiment 1 – Voiceless and voiced stops

2.1 Method

2.1.1 Participants

Five native speakers (2 male, 3 female) of SMG, all in their twenties, were recorded. Recordings took place in an isolated recording booth at the University of Edinburgh. None of the participants had spent more than one year in the UK.

2.1.2 Materials

Speakers produced sentences containing the voiceless and voiced stops of Modern Greek in five prosodic positions (i.e., the strength of the boundary at the vicinity of which they appeared was gradually stronger, see Appendix A for template of constructing materials and for an example). These boundary conditions will henceforth be referred to as BC1-5, with BC1 having the weakest and BC5 the strongest boundary. In addition to materials for voiceless and voiced stops of SMG this production experiment included materials for SV. Clusters of 'nasal+stop' were placed at the exact same boundary conditions³. Moreover, one extra condition was created specifically for SV, named BC0. Items for this condition can be seen in Table 1. I focus on this final construction since, as we will see in §3.2.1, it is the only condition within which SV takes place. In addition, this is the domain designed to further probe Nespor and Vogel's (1986) analysis (see §1.1), since materials include words like /otan/ and /ðen/.

Particle		Verb
/otan/ 'when'	+	/pace'taris/ 'pack'
/an/ 'if'		/taksi'ðevis/ 'travel'
/ðen/ 'not'		
/min/ 'not'		/kata'jelis/ 'denounce'
/ton/ 'him'		

Table 1 Materials used for the lowest prosodic condition examining SV

Speakers produced a total of 850 instances [voiceless vs. voiced stops: 5 speakers*6 items*5 boundary conditions*2 repetitions = 300 plus for 'nasal+stop' sequences: 5 speakers*8 items*5 boundary conditions*2 repetitions = 300 items plus for BC0 of 'nasal+stop' sequences: 5 speakers*3 items*1 condition*2 repetitions*5 particles = 150].

2.1.3 Acoustic measurements

- A. *Duration of Closure and Release*: release refers to the time taken from the release of the closure to the beginning of vocal fold vibration of the *following* vowel (it, therefore, cannot be equated to VOT).
- B. *Relative Amplitude of Closure and Release*: the amplitude at the mid-point of the closure and release was measured, as shown in Figure 1. Measurements were performed automatically in PRAAT using a minimum pitch value of 100Hz (that is, the resulting window frame over which the analysis for amplitude is performed is 18ms, with 9ms on each side of the point of measurement). These raw measurements were then normalised by subtracting the mid-point amplitude measurement of the pre-boundary vowel from the measurement of the closure and the release:

$$\text{Relative Amplitude} = \text{dB of Closure/Release (midpoint)} - \text{dB of Vowel (midpoint)}$$

³ Notice that while the production experiment for voiceless and voiced stops of SMG includes the design and elicitation of SV instances, these are analysed in §3.2.3, and not in this section.

Given that vowels have higher amplitude than the closure and release of stops, negative values are expected, and lower absolute values indicate higher amplitude (e.g. a value of -8 in comparison to -11 means that the first sound has a higher amplitude than the second).

Figure 1 Example of segmentation of closure and release depicting the window for amplitude measurements

2.2 Results

Four Univariate ANOVAs are performed, testing the effect of Stop category (voiceless vs. voiced) on duration of closure, duration of release, relative amplitude of closure and relative amplitude of release. The effect of Stop category is significant in all four ANOVAs (Table 2). The closure of voiceless stops is 20% shorter than that of voiced stops ($F(1,271)=45.521$, $p<.001$) and the duration of the release for voiceless stops is 42% longer than for voiced stops ($F(1,285)=150.290$, $p<.001$). The amplitude of the closure and of the release are significantly lower for voiceless than for voiced stops (82% difference for the closure and 80% for the release ($F(1,247)=563.993$, $p<.001$, and $F(1,258)=295.8$, $p<.001$ respectively⁴). Table 3 shows the results for each place of articulation separately (asterisks indicate a difference between the voiceless and voiced stop).

	Voiceless	Voiced	Significance
Closure duration	51ms	64ms	* $<.001$
Release duration	24ms	14ms	* $<.001$
Closure amplitude	-17dB	-3dB	* $<.001$
Release amplitude	-10dB	-2dB	* $<.001$

Table 2 Mean duration and relative amplitude of voiceless and voiced stops in SMG

	p	t	k	b	d	g
Closure duration	63	44	45	65	70*	58*
Release duration	18	23	23	11*	13*	16*
Closure amplitude	-18	-14	-19	-3*	-2*	-3*
Release amplitude	-9	-10	-12	-1*	-1*	-4*

Table 3 Mean duration and relative amplitude of voiceless and voiced stops in all places of articulation (asterisks indicate statistical difference between voiceless and voiced rendition)

A Binary Logistic Regression analysis tested which of the four variables is the most important predictor for the voiceless-voiced classification. The most important predictors are the duration and

⁴ All boundary conditions have been pooled in these results, which means that mean results stem from a variety of prosodic contexts. For a breakdown of the results in each boundary condition, see Appendix B.

amplitude of the closure, while those of the burst do not significantly contribute to the model. A discriminant analysis showed that by using only the duration and amplitude values of the closure, 98.4% of the data can be correctly classified as voiceless or voiced. While this suggests that the acoustic characteristics of the closure are very important in the voicing distinction, it is not to be taken that they alone contribute to that, since a discriminant analysis testing the predictive power of only the acoustic characteristics of the release showed that 88.1% of the data can still be correctly classified.

2.3 Summary

Experiment 1 showed that the duration and amplitude of voiceless and voiced stops in SMG differ significantly. In terms of their amplitude, as expected, voiced stops have higher values. Interestingly, in terms of their duration, there is an interplay between the duration of the closure and that of the release, whereby the closure is longer for voiced stops than voiceless, and conversely the release longer for voiceless than voiced stops. Finally, the acoustic characteristics of the closure emerged as the most significant factors in distinguishing statistically between the voiceless and voiced categories.

3. Experiment 2 – Perception and acoustics of post-nasal stop voicing

A perception experiment was performed with the goals of (i) investigating the domain within which SV occurs, and (ii) on the basis of speakers' classifications as to which instances of 'nasal+stop' have undergone voicing, to compare their acoustic characteristics to those from voiceless and voiced stops in Experiment 1.

3.1 Methodology

Three raters, native speakers of SMG, classified all items from Experiment 1, i.e. both 'nasal+stop' sequences and phonologically voiceless and voiced stops (baselines). The nasal was located at the end of the word and was followed by a stop at the beginning of the next word. To avoid lexical bias, raters only listened to the syllables preceding and following the word boundary. Each rater heard the same number of items [272 bilabials, 268 palatals/velars and 206 alveolars] with different randomizations across speakers. The experiment was run in PRAAT (Boersma 2001). The raters were asked to listen to the items and decide whether they heard a voiceless or voiced stop⁵. Each rater did the experiment three times – one for each place of articulation.

3.2 Results

3.2.1 Prosodic boundary strength effects on post-nasal stop voicing application

Inter-rater agreement is first quantified using the *kappa statistic*. This statistic evaluates whether agreement has reached an acceptable level (Siegel and Castellan 1988), taking into consideration chance agreement between raters. Its output varies between -1 (no agreement) and 1 (full agreement), therefore expected results should lie between 0 (chance agreement) and 1. The level above which agreement is considered satisfactory is not uniformly agreed upon by researchers but a number above 0.65-0.70 is generally considered adequate for further analyses (personal communication with Dr. J. Carletta, and see Carletta 1996).

The results show very high inter-transcriber agreement for all three places of articulation, specifically $k=0.888$ for alveolars, $k = 0.845$ for bilabials, and $k = 0.901$ for velars], indicating that voicing judgments were easy for raters.

Figure 2 shows how often raters classified a 'nasal+stop' cluster as voiced or voiceless across all boundary conditions. It can be seen that SV is allowed in BC0 and blocked in all other conditions, indicating that the phenomenon is confined within the lowest domain of the hierarchy. Moreover, there

⁵ Four options were actually made available to the speakers; voiced or voiceless with the sub-categorisation of them being preceded by a nasal component. Those were collapsed to only two categories for the purposes of the analyses.

is an approximately 60-40% divide between SV applying vs. not applying, suggesting that the rule is optional. In the following section, its behavior within this domain is examined in detail.

Figure 2 Percentage perceptual classification of ‘nasal+stop’ clusters as voiced or voiceless

3.2.2 Gradience within the same domain

When designing the lowest condition for the perception experiment, the items created entailed a variety of lexical items such as negation and temporal particles, subjunctive particles etc (see Table 1). This was done with the goal of probing potential differences across items within the same domain, and testing different expectations from analyses by Nespor and Vogel (1986) and possibly Malikouti-Drachman and Drachman (1988). For example, /ðen/ and /'otan/ according to Nespor and Vogel (1986) form different CG constructions (although the reasons for that are not clear), generating the hypothesis that the two items should behave differently in our experiment (/’otan/ should never voice and /ðen/ should voice). With respect to Malikouti-Drachman and Drachman’s (1988) analysis we might be able to form a prediction for /ðen/, /ton/ and /min/, in that in terms of syllabification they should not differ. The generated hypothesis would therefore be that all three lexical items should be optionally voiced following similar trends. Table 4 shows the amount of times each item was classified by the raters as voiced or not, broken down by item.

	Voiceless	Voiced	No Agreement
/ðen/ (‘not’) (9430,8)	-	19	5
/ton/ (‘him’) (8677,8)	5	17	5
/tin/ (‘her’) (18625,8)			
/min/ (‘not’) (696,2)	8	11	9
/an/ (‘if’) (2520,1)	12	5	5
/’otan/ (‘when’) (1514,2)	10	3	7

Table 4 Number of times each ‘nasal+stop’ cluster from each lexical item was classified as voiceless or voiced by all raters, and number of times classification did not reach agreement across raters. Numbers in *italic* parentheses show frequency of the lexical type in a million (Protopapas et al in press)

What is notable from Table 4 is that in BC0 there are indeed differences across lexical items in how often they are classified as voiceless and voiced; while the negation particle /ðen/ always undergoes

voicing, the other negation particle /min/ is split almost in half, with many instances of disagreement across raters, and at the other end temporal and subjunctive particles /otan/ and /an/ are classified as voiced only a few times. Interestingly, this variability is gradient; /ðen/ is always voiced, /ton/ follows with many instances of SV, and then /min/ with less SV instances and more instances of no agreement between raters, while /otan/ and /an/ appear to be mostly voiceless. Therefore, the hypothesis on the basis of Nespor and Vogel's (1986) analysis is half-met, in that /otan/ behaves differently to /ðen/ (but is still voiced a few times), while the second hypothesis regarding /ðen/, /min/ and /ton/ is not met at all, since the behavior of the three items differs.

The frequency of each lexical item from Protopapas et al's (in press) corpus is shown in Table 4 in italic parentheses in the first column. The most frequent item (/ðen/) always voices, while the least frequent items (/otan/ and /an/) voice the least frequently, and /ton/ lies in between in terms of both lexical and voicing frequency. However, this interesting pattern does not pertain to /min/, an item that voices often, but which appears the least frequently in the language.

3.2.3 Acoustics of post-nasal stop voicing

Two issues are addressed in this section with respect to SV: (i) the acoustic characteristics of instances of 'nasal+stop' classified as having undergone voicing, and (ii) their comparison to the acoustics of voiceless and voiced stops of SMG, as seen in Experiment 1⁶.

Four Univariate ANOVAs are performed, testing the effect of Stop category (this time instances *classified as* voiceless vs. voiced) on duration of closure, duration of release, relative amplitude of closure and relative amplitude of release. The effect of voicing is significant on all dependent variables (pooling all prosodic conditions: Closure Duration: $F(5, 20) = 5.989$, $p < .01$, Release duration: $F(5, 20) = 6.694$, $p < .01$, Relative Amplitude of Closure: $F(5, 20) = 4.365$, $p < .01$, Relative Amplitude of Release: $F(5, 20) = 4.433$, $p < .01$). This suggests that 'nasal+stop' clusters classified as voiced are statistically different to those classified as voiceless.

Moreover, the same pattern as in §2.2 is replicated (Table 5); the duration of the release of the voiceless items is longer than for the voiced and amplitude is higher for voiced than voiceless renditions both in the closure and the release. However, the duration of the closure of the voiceless items is also longer than that of the voiced, contrary to what was found in §2.2. This mismatch stems from the fact that almost all instances classified as voiced are derived from BC0, the lowest condition. Taking into consideration that boundary strength exercises lengthening effects in the preceding and following syllables and sounds (Fougeron and Keating 1997, Kainada 2010b for SMG), it becomes clear that all instances from BC1-BC5 (which were in their majority voiceless) will have longer closure durations than BC0 (which included in its majority voiced stops). On the basis of post-boundary lengthening being more pronounced in the vicinity of stronger prosodic boundaries, it is therefore expected that BC0 will have shorter durations than BC1-BC5. Given that all of the voiced instances are within BC0, the comparison between voiceless and voiced 'nasal+stop' sequences with respect to the duration of closure is not reliable. To rectify this issue, the difference between voiceless and voiced stops only in BC0 was tested; voiceless stops indeed have shorter closure duration than voiced ones⁷.

	Voiceless	Voiced
Closure duration	43	38
Release duration	24	15
Closure amplitude	-14	-8
Release amplitude	-18	-7

Table 5 Mean duration and amplitude of closure and release for all 'nasal+stop' sequences classified as voiceless and voiced

⁶ Remember that the production of all 'nasal+stop' sequences was performed in Experiment 1 and are analysed here. The reason for that is that first we need to perceptually classify which instances have undergone SV, before examining their acoustics. Therefore, the perception experiment is needed before any acoustic analyses are performed.

⁷ Instances of 'No Agreement' between raters were also investigated and were found to have acoustic characteristics similar to the items classified as voiceless, and statistically different to those of instances classified as voiced. It is not clear why those instances did not reach agreement. A spectrographic analysis was also performed by the author, confirming them visually as voiceless.

3.3 Summary

Experiment 2 showed that SV applies at the lowest domains of the prosodic structure. Importantly, there is variation in SV application within that domain, in that some lexical items are voiced more often than others, and the process appears to be optional. Acoustically, SV instances share the same durational and amplitude characteristics as voiced stops of SMG, and are statistically different to voiceless renditions. All the above show that SV applies categorically and is influenced by prosodic boundary strength in a categorical manner too.

4. Discussion

This paper set out to answer two questions. First, whether SV is categorical and, second, how is SV influenced by boundary strength. Acoustically, SV is categorical, i.e. the duration and amplitude of instances having undergone SV are distinct (both perceptually and statistically) to those of instances that have not undergone voicing. Moreover, SV instances were acoustically similar to voiced stops of SMG, and statistically dissimilar to voiceless stops. This is interesting because much acoustic research on sandhi phenomena in several languages over the past decade reports that such phenomena do not fit in acoustically distinct categories, but vary in a continuum of possible acoustic values. In fact, such findings have led to questioning whether sandhi phenomena are the result of a phonological rule or of coarticulation. The results of this paper clearly indicate that SV in SMG is a categorical process whose application seems to be the result of phonological planning and whose occurrence needs to be explained phonologically and not in terms of coarticulation. With respect to the boundary strength on the application of SV it was shown that SV is influenced categorically by prosodic boundary strength; SV is allowed only within the lowest domains of the prosodic hierarchy.

The second issue addressed concerns the way SV applies within the lowest domains of the prosodic structure. It was shown that frequency of voicing varied across lexical items, with /ðen/ emerging as always voiced, and /otan/ and /an/ being the items with the least amount of voicing. According to Nespor and Vogel's (1986) analysis this can be explained on the basis of different CGs; /otan/ and /an/ form CGs on their own, and therefore SV is blocked across them. However, this does not explain why these items were still classified as voiced in some instances, nor does it explain the phonological or other characteristics of /otan/ and /an/ that force them to form CGs (in comparison to items such as /ðen/ or /ton/). Finally, Nespor and Vogel's (1986) analysis cannot account for the gradient variation found across lexical items, whereby /ðen/ is always voiced, /min/ and /ton/ are sometimes voiced, and /otan/ and /an/ are almost never voiced (especially so for /ðen/ and /min/ which are both negation particles, unstressed, monosyllabic, and followed by the exact same verbs). Malikouti-Drachman and Drachman's (1988) analysis on the basis of syllabification cannot account for the findings either. All particles included in the experiment were followed by the exact same verbs, thus giving rise to the same syllabification conditions. Even if the nasal is optionally attached at the onset of the following syllable or at the coda of the preceding, we need an explanation as to why, for example, negative particles /ðen/ and /min/ behave differently, and why the object-clitic /ton/ is less frequently voiced than the negation particle /ðen/.

One possible explanation for the described variation could be the frequency of the words involved in the overall language. It was shown in §3.2.2 that a correlation could be loosely identified between the frequency of the lexical item in the language and the amount of times it exhibited SV, but this correlation did not pan out for all items under investigation (/min/ did not fit the pattern). This may indicate a process currently in progress in SMG whereby some items (the most frequent ones) undergo SV more often than others, but this is speculative and does not seem to apply to all items investigated. If this is the case, SV in SMG would prove an excellent test bed to test articulatorily how the process evolves, which could give insights into the link between coarticulation and sandhi phenomena.

ABSTRACT

This study examines aspect and telicity in the production and comprehension of activity and motion verbs in the Greek of early successive bilingual Albanian-Greek children. In Greek, telicity is compositionally determined by morphological and situation type aspect and by a quantized object (Borer 2005). A telic sentence has an endpoint (DP or PP complement for activity and motion respectively) beyond which the event cannot continue (Depraetere 2007). The results show that the aspectual marking of telicity in activities appears earlier than in motion verbs. Bilingual children rely primarily on verb type differences in coding morphological aspect.

Keywords: aspect, telicity, motion verbs, L2 Greek, early successive bilingualism

1. Introduction

Telicity is a notion that has been used to characterize verbs, predicates and sentences. Vendler's classification of verbs distinguishes between states and activities being atelic from achievements and accomplishments being telic (Vendler 1967, Dowty 1979). Smith (1991) discusses the shift from one situation type (i.e. aspectual verb class) to the other as in *build*, an activity, to *build a house*, an accomplishment. This shift renders the atelic verb into a telic predicate. A sentence is telic if the event is represented as having an endpoint beyond which the event cannot continue (Depraetere 2007). The visibility of the endpoint depends on different factors such as the lexical semantics of a verb (e.g. find, sneeze, explode), the presence of a PP-GOAL which acts as a boundary of the action denoted by the verb (e.g. He drove the car into the garage), contextual knowledge shared by discourse participants (e.g. He sang. *understood as* He sang a song, specific object NPs which provide the natural endpoint to the situation (e.g. drink a glass of wine).

Accordingly, telicity is a notion relevant to the syntax-discourse interface in that it enables the hearer to view the event with or without a natural endpoint. However, the visibility of the endpoint may be established and unambiguously determined within the sentence and prior to pragmatic interpretation through lexical or grammatical means. Alternatively, the endpoint of the event described by the sentence may not be determined at the sentence level but may be inferred from an interaction of linguistic and contextual information. Both options can be available within the same language (Verkuyl 1993, Krifka 1989). For example, the Greek sentence *Zografise ena portreto* ("He painted a portrait") is unambiguously telic in that the portrait is completed while the sentence *Zografize ena portreto* ("He was painting a portrait") leaves open the possibility that the portrait is still not completed (Tsimpli & Papadopoulou 2006)¹. The crucial difference between the two sentences is the perfective/imperfective aspect on the verb form. Since perfectivity makes visible the endpoint of the event (Smith 1991) the presence of the object serves to identify the endpoint with the completion of the object painting event.

¹ The atelic interpretation also arises if there is no object at all with either perfective or imperfective verbs or if the object is a bare indefinite (Tsimpli & Papadopoulou 2006):

- (i) a. Zografize / Zografise
was-painting / painted
"He was painting. / He painted."
- b. Zografize / Zografise portreta.
was-painting / painted portraits
"He was painting / painted portraits."

The imperfective aspect, on the other hand, does not make visible the endpoint of the event and consequently the specific object leaves open the possibility of either identifying the completion point of the portrait or not. Thus, in Greek telicity can be unambiguously defined within the sentence with the combination of perfective aspect and a specific object DP (cf. Mozer 1994; Chila-Markopoulou and Mozer 2001). Furthermore, even when telicity is unambiguously defined within the sentence, in Greek this is the result of a compositional interpretation of the aspectual form and the quantized object or a PP-GOAL, to which we turn immediately.

Zubizarreta & Oh (2007) propose that there is a semantic and syntactic distinction between motion verbs, reflecting argument structure differences. Specifically, whether the motion verb includes an inherent ‘directed motion’ feature or not is linked with the possibility of selecting a PP-PATH/GOAL complement. Accordingly, the bare motion verb ‘to go’ includes a directed motion feature which is expressed through a PP-complement whereas manner-of-motion verbs are divided into the ‘run’ type manner of motion verbs which can take a distance DP complement and the ‘wander’ type which cannot. The directed motion feature is included in the former but not in the latter. Motion verbs in Greek are the focus of our experimental study. Greek and Albanian show an interesting asymmetry in the ambiguity and lack thereof of (a)telic interpretations respectively. Consider the following Greek examples first:

- (1) a. O skilos etrehe ston kipo.
the dog ran.IMP-3S in-the garden
“The dog was running in/towards the garden.
b. O skilos etrekse ston kipo.
the dog ran.PERF.3S in-the garden
“The dog ran into/towards/inside the garden.”

Each of the two sentences in (1a) and (1b) is ambiguous between a telic and an atelic interpretation. Specifically, in (1a) the PP *ston kipo* can be construed as the GOAL argument which depicts the direction of the motion event or as the LOCATIVE modifier of the motion event which, in this case, is neither directional nor measured. In (1b), on the other hand, the ambiguity increases since the telic interpretation in which the PP-GOAL is interpreted as the endpoint of the event is also available. Thus, in (1a) the event is unbounded and therefore atelic while in (1b) the telic interpretation is possible. Despite the ambiguity just described, there is a strong preference for the atelic locative interpretation in (1a) and the telic in (1b). These preferences are associated with the aspectual distinction on the verb form in each case. The imperfective may only denote atelic² events, i.e. location or direction while the perfective form is ambiguous between the two atelic readings and the telic interpretation (cf. Horrocks and Stavrou 2007). Nonetheless, Greek native speakers seem to favor a particular reading with each aspectual form. In previous studies (Tsimpli & Papadopoulou 2009) it was found that Greek monolingual adults prefer to interpret sentences such as (1b) as telic, while sentences such as (1a) as locative.

Albanian has two distinct morphologically simple past “tenses”, the “Imperfect” and “Past Definite” which differ in terms of their (im)perfectivity value (Dalina Kalluli p.c). The morphological and interpretive differences between Past Definite and Imperfect for the activity verb *lexoj* ‘I read’ are illustrated in (2) versus (3).

- (2) Vajza lexoi gazetën.
girl.the read.3s,DP newspaper.the
‘The girl read the newspaper.’

(3) Vajza lexonte gazetën.
girl.the read.3s,IMP newspaper.the
(i) ‘The girl was reading the newspaper.’
(ii) ‘The girl used to read the newspaper.’

The Imperfect may yield either a progressive reading occurring at a time in the past (as rendered in (3i)), or a habitual one (as rendered in (3ii)). Perfective motion verbs followed by a PP do not necessarily yield a telic interpretation (4).

² Notice that imperfective manner-of-motion verbs may denote telic events when they are used to express habituality (cf. Tsimpli & Papadopoulou 2009).

- (4) Vajza vrapoi në dyqan.
 girl.the run.3s,PD to/in/for store
 (i) ‘The girl ran to the store.’ → telic
 (ii) ‘The girl ran in the store.’ → atelic
 (iii) ‘The girl ran for the store.’ → atelic

Imperfective motion verbs always yield atelic interpretations (5):

- (5) a. Vajza (po) vraponte në dyqan.
 girl.the PROG run.3s,IMP in/to/for store
 ‘The girl was running in/to/for the store’
 b. Vajza vraponte në dyqan.
 girl.the run.3s,IMP in/to/for store
 (i) ‘The girl was running in/to/for the store’
 (ii) ‘The girl used to run in/to/for the store’

One difference between Greek and Albanian is in the availability of a progressive marker (‘po’) in Albanian but not in Greek. Thus, the distinction in terms of aspectual features is [+/-perfective] for Greek and [+/-perfective] as well as [+/-progressive] in Albanian.

2. Research Questions

The aim of the study is to investigate the role of the aspectual verb form (Perfective *vs.* Imperfective) in combination with the complements (DPs *vs.* PPs) in the comprehension and production of activity and motion verbs by young successive bilingual learners. Research questions: (1) do early bilingual Albanian-Greek children show the same developmental pattern as monolingual L1 Greek with reference to the expression and perception of telicity? (2) if a delay is attested in bilinguals, does it relate to the motion *vs.* activity predicate distinction? (3) does the L1 aspectual system interfere with the comprehension and production of telicity in L2 Greek?

3. The Study

Two groups of bilingual Albanian-Greek children participated in the study. There were 40 participants in total and were drawn from two state schools in Thessaloniki and a private institution for the teaching of Albanian literacy skills to Albanian children run by an immigrant association³. For each age group there were 20 participants. At the time of testing, the Bil_1 group had a mean age of 7;8 yrs old (Female: 7 & Male: 13) and the Bil_2 group a mean age of 9;1 yrs old (Female: 8 & Male: 12). A linguistic background questionnaire was distributed to the parents/guardians of participants and the information collected is presented on Table 1.

Group	Age at Testing	Home Language	Birth Place	Minimum Length of Exposure to L2 Greek	Bilinguals with Literacy Skills in L1 Albanian
Bilingual_1 (N=20)	7;8 yrs old (7;7-8;9)	Albanian & Greek (N=18) Albanian (N=2)	Greece (N=18) Albania (N=2)	6 yrs	60% (N=12)
Bilingual_2 (N=20)	9;1 yrs old (8;10-10;4)	Albanian & Greek (N=16) Albanian (N=4)	Greece (N=16) Albania (N=4)	7 yrs	70% (N=14)

Table 1 Bilingual Participants Profile

³ We would like to thank the 6th Intercultural Primary School of Eleftherio-Kordelio, the 6th Primary School of Evosmos and the immigrant association Mother Teresa for participating in this study and offering their help for the conduction of the experiments and the selection of information on the learners’ background.

Additionally, four control groups of monolingual speakers of Greek participated in the study; in particular, three monolingual learners groups and an adult group of 20 participants each (Total N of monolinguals: 80). At the time of testing, the monolingual 5-6 yrs old group had a mean age of 5;5 (Female: 25 & Male: 25), the monolingual 6-7 yrs old group a mean age of 6;4 (Female: 27 & Male: 23), the monolingual 7-8 yrs old one a mean age of 7;4 (Female: 26 & Male: 24), and the adult native speakers group a mean age of 36;5 (Female: 27 & Male: 13).

3.1 Aspectual Marking Pre-test

In order to establish that the bilingual participants have acquired the perfective-imperfective distinction regardless of telicity or other factors, we used a sentence completion task designed by Agathopoulou & Papadopoulou (2009)⁴. The participant was given a sentence to complete using the verb provided either in perfective, as in example (6) or in imperfective, as in example (7):

- (6) Hthes o Nikos yirise sto spiti *stis* 8.
Yesterday the Nick return-PERF home at 8 o'clock.
'Yesterday Nick returned home at 8 o'clock.'
- (7) Hthes sto parti tis Elenis o Nikos horeve *sinehia*.
Yesterday s-the party the Helen the Nick dance-IMP continuously.
'Yesterday Nick was dancing continuously at Helen's party.'

There were 32 items and the type of aspect was controlled by time adverbials expressing punctuality (in example (6) *stis* 8) or continuity (in example (7) *sinehia*). The accuracy score for the Bil_1 group was 85.19% and for the Bil_2 group 93.25%. Both scores show an established knowledge of aspectual marking.

3.2 The Comprehension Study

The comprehension experiment examines the understanding of telicity in the bilingual grammar of young successive bilingual learners.

3.2.1 Materials

The comprehension task designed by Kaltsa (in prep.) consisted of 64 short video stimuli. For each verb, we constructed two videos the one presenting a telic/complete event and the other an atelic/ongoing one. Each aspectual verb form [+/- Perfective] was presented with the same pair of videos. There were 18 target verbs (6 intransitive, 6 activity and 6 motion verbs) and 14 filler verbs. The verbs employed in the task in intransitive constructions were *hamogelo* ('smile'), *kimame* ('sleep'), *kleo* ('cry'), *spao* ('break'), *klino* ('close') and *pefto* ('fall'). The activity verbs were *zografizo* ('paint'), *dhiavazo* ('read'), *troo* ('eat'), *pino* ('drink'), *katharizo* ('clean') and *ftiaho* ('make'). The motion verbs were *strifogirizo* ('turn around'), *sernome* ('crawl'), *treho* ('run'), *pidho* ('jump'), *pigeno* ('go') and *horopidho* ('gambol'). An example of sentences with activity VPs employed in the task may be seen in (8) and an example of motion VPs in (9).

- (8) (a) Hthes to koritsi efage ena milo.
yesterday the girl eat-PERF an apple
'Yesterday the girl ate an apple.'
- (b) Hthes to koritsi etroge ena milo.
yesterday the girl eat-IMP an apple
'Yesterday the girl was eating an apple.'
- (9) (a) Hthes to agori etrekse sti kuzina.
yesterday the boy run-PERF to/in the kitchen
'Yesterday the boy ran to the kitchen.'

⁴ The original test (Agathopoulou & Papadopoulou 2009) was designed to be a written sentence completion task. In our study we modified the test so that it was administered in both written and spoken form in order to alleviate the written language burden from the bilingual children tested.

- (b) Hthes to agori etrehe sti kuzina.
 yesterday the boy run-IMP in the kitchen
 'Yesterday the boy was running inside the kitchen.'

In (8a), the perfective activity VP is expected to map onto a telic interpretation, that is a completed event where the goal has been accomplished (the whole apple has been consumed). In the case of the imperfective activity VP (8b), the utterance may only refer to an atelic event during which the goal has not been achieved (the apple remains uneaten). In (9a), the perfective motion VP can be interpreted either as telic or atelic. In order to receive a telic interpretation the PP needs to be interpreted as a goal (directional reading). The local interpretation of the PP, on the other hand, will lead to an atelic reading of the sentence. In the case of the imperfective motion VP (9b), the interpretation of the PP may only be locative and it consequently leads to an overall atelic interpretation.

3.2.2 Procedure

The participants were shown both videos presenting the telic and atelic condition simultaneously and a recorded stimulus sentence followed. The stimulus sentence was morphologically marked either with Perfective or Imperfective aspect and the task for the participant was to match this utterance to one of the two events. The experiment was conducted with the use of a laptop computer with a 15.4" screen. The participants were given the following protocol before starting the experiment: A robot was introduced to the participants on the computer screen. He/she was told that this robot had been learning Greek and the previous day it was watching two kids doing several things. The robot would describe what those kids were doing but it was not really sure how to use Greek accurately so it needed the participant's help. The participant had to watch carefully both videos, listen to what the robot says and point to the video that is best described by the robot's utterance.

3.2.3 Results

The data analysis consisted in counting the preferred matching of perfective aspectual verb forms with a telic or atelic interpretation of the events and imperfective aspectual verb forms with a telic or atelic interpretation. The data was subcategorized per verb type. The mean percentages of aspect-telicity matching per age group are presented in Figures 1 to 4.

Activity and Telicity in L2 Greek

In activity VP constructions, the interaction of aspect (perfective vs. imperfective) and event type (telic vs. atelic) is not significant only for the Bil_1 group data. For the other groups, the interaction between aspect and telicity is significant (Bil_1: 1: $\chi^2=.137$, $df= 1$, $p= .711$; Bil_2: $\chi^2= 10.474$, $df= 1$, $p= .001$; Monol_5-6-yrs-old: $\chi^2= 4.800$, $df= 1$, $p= .028$; Monol_6-7-yrs-old: $\chi^2= 43.982$, $df= 1$, $p= .000$; Monol_7-8-yrs-old: $\chi^2= 108.330$, $df= 1$, $p= .000$; Monol_adults: $\chi^2= 120.000$, $df= 1$, $p= .000$).

Figure 1 presents the mean percentages of perfective activity verbs' interpretation as telic and atelic per group.

Figure 1 Perfective Activity VPs

The data reported in Figure 1 show that both bilingual groups prefer to match telic events to perfective activity verb forms. This observation was statistically supported by one-way-goodness-of-fit chi-square tests (Bil_1: $\chi^2 = 9.600$, $df = 1$, $p = .002$; Bil_2: $\chi^2 = 19.267$, $df = 1$, $p = .000$). The data of the control groups show that 5-6 yrs old monolingual children have not developed a strong enough preference for the telic interpretation (Monol_5-6-yrs-old: $\chi^2 = 2.400$, $df = 1$, $p = .121$). The rest of the monolingual children along with the adults, though, significantly prefer to match telic events to perfective activity VPs (Monol_6-7-yrs-old: $\chi^2 = 32.267$, $df = 1$, $p = .000$; Monol_7-8-yrs-old: $\chi^2 = 56.067$, $df = 1$, $p = .000$).

Figure 2 presents the mean percentages of imperfective activity verbs' interpretation as telic and atelic per group.

Figure 2 Imperfective Activity VPs

The data reported in Figure 2 show that both bilingual groups along with Monol_5-6 yrs old group remain indeterminate when matching imperfective activity VPs to telic and atelic events. This observation was statistically supported by one-way-goodness-of-fit chi-square tests (Bil_1: $\chi^2 = .600$, $df = 1$, $p = .439$; Bil_2: variable constant; Monol_5-6-yrs-old: $\chi^2 = 2.400$, $df = 1$, $p = .121$). The Monol_6-7 and Monol_7-8 yrs old groups align with the adult preferences (Monol_6-7-yrs-old: $\chi^2 = 13.067$, $df = 1$, $p = .000$; Monol_7-8-yrs-old: $\chi^2 = 52.267$, $df = 1$, $p = .000$).

Turning to the comparison between the two bilingual groups for activity verbs, no significant differences are found in the perfective or in the imperfective condition. Monolingual groups, in

contrast, differ from each other in both aspectual conditions and the oldest group reaches adult performance (Kaltsa in prep.). Comparing each bilingual with each monolingual group it is shown that in the perfective condition Bil_1 aligns with the performance of Monol_5-6 yrs old group and Bil_2 with that of Monol_6-7 yrs old group suggesting a minimum of two years delay in the acquisition of perfective aspectual marking on activity VPs (Bil_1 vs. Monol_5-6-yrs-old: $\chi^2= 1.319$, $df= 1$, $p= .251$; Bil_1 vs. Monol_6-7-yrs-old: $\chi^2= 4.910$, $df= 1$, $p= .027$; Bil_1 vs. Monol_7-8-yrs-old: $\chi^2= 18.072$, $df= 1$, $p= .000$; Bil_1 vs. Monol_adults: $\chi^2= 21.176$, $df= 1$, $p= .000$; Bil_2 vs. Monol_5-6-yrs-old: $\chi^2= 4.728$, $df= 1$, $p= .030$; Bil_2 vs. Monol_6-7-yrs-old: $\chi^2= 1.443$, $df= 1$, $p= .230$; Bil_2 vs. Monol_7-8-yrs-old: $\chi^2= 11.644$, $df= 1$, $p= .001$; Bil_2 vs. Monol_adults: $\chi^2= 14.579$, $df= 1$, $p= .000$).

The same comparison in the imperfective activity verb condition shows that both bilingual groups align with the lack of a strong preference found also in the Monol_5-6 yrs old group. This suggests an further delay in the imperfective activity Vs (Bil_1 vs. Monol_5-6-yrs-old: $\chi^2= 2.707$, $df= 1$, $p= .100$; Bil_1 vs. Monol_6-7-yrs-old: $\chi^2= 9.968$, $df= 1$, $p= .002$; Bil_1 vs. Monol_7-8-yrs-old: $\chi^2= 38.763$, $df= 1$, $p= .000$; Bil_1 vs. Monol_adults: $\chi^2= 45.517$, $df= 1$, $p= .000$; Bil_2 vs. Monol_5-6-yrs-old: $\chi^2= 1.212$, $df= 1$, $p= .271$; Bil_2 vs. Monol_6-7-yrs-old: $\chi^2= 6.910$, $df= 1$, $p= .009$; Bil_2 vs. Monol_7-8-yrs-old: $\chi^2= 33.409$, $df= 1$, $p= .000$; Bil_2 vs. Monol_adults: $\chi^2= 40.000$, $df= 1$, $p= .000$).

Motion and Telicity in L2 Greek

In motion VP constructions, the interaction of aspect (perfective vs. imperfective) and event type (telic vs. atelic) appears quite difficult for young learners, bilingual and monolingual. In particular, no effect of this interaction is found in the performance of Bil_1 and Monol_5-6 yrs old groups (Bil_1: $\chi^2= 1.656$, $df= 1$, $p= .198$; Monol_5-6-yrs-old: $\chi^2=.333$, $df= 1$, $p= .564$). Bil_2, on the other hand, as well as the rest of the monolingual controls show a significant interaction (Bil_2: $\chi^2= 17.638$, $df= 1$, $p= .000$; Monol_6-7-yrs-old: $\chi^2= 20.000$, $df= 1$, $p= .000$; Monol_7-8-yrs-old: $\chi^2= 83.426$, $df= 1$, $p= .000$; Monol_adults: $\chi^2= 112.258$, $df= 1$, $p= .000$).

Figure 3 presents the mean percentages of perfective motion verbs' interpretation as telic and atelic per group.

Figure 3 Perfective Motion VPs

Note that the data in Figure 3 differ from those in Figure 1 for activity verbs both for bilinguals and monolinguals. Perfective aspect for motion verbs appears to be problematic for the Bil_1, Monol_5-6 and Monol_6-7 yrs old groups, whereas it is strongly related to a telic event for the older bilinguals and the 7-8 yrs old monolingual children (Bil_2: $\chi^2= 8.067$, $df= 1$, $p= .005$; Monol_7-8-yrs-old: $\chi^2= 38.400$, $df= 1$, $p= .000$; Monol_adults: $\chi^2= 52.267$, $df= 1$, $p= .000$).

Figure 4 presents the mean percentages of imperfective motion verbs' interpretation as telic and atelic per group.

Figure 4 Imperfective Motion VPs

Comparing Figures 2 and 4, we note that imperfective motion events are readily interpreted as atelic while imperfective activities are at chance with respect to telicity. Figure 4 shows that both bilingual and monolingual groups match atelic events to imperfective motion verb forms. This observation was statistically supported by one-way goodness-of-fit chi-square tests (Bil_1: $\chi^2=3.267$, $df=1$, $p=.071$; Bil_2: $\chi^2=9.600$, $df=1$, $p=.002$; Monol_6-7-yrs-old: $\chi^2=21.600$, $df=1$, $p=.000$; Monol_7-8-yrs-old: $\chi^2=45.067$, $df=1$, $p=.000$).

Developmentally, the between bilingual group comparisons for motion verbs show a difference only in perfective aspect (Bil_1 vs. Bil_2: $\chi^2=4.174$, $df=1$, $p=.041$). The comprehension of aspectually marked motion VPs is an area of difficulty for monolingual children as well, who are found to differ from each other but still not attain the adult like preferences for the (a)telic interpretations (Kaltsa in prep.). The comparison between bilingual and monolingual groups reveal that in the perfective aspect condition Bil_1 aligns with the performance of Monol_5-6 yrs as well as Monol_6-7 yrs old groups, while Bil_2 with that of Monol_6-7 yrs old group (Bil_1 vs. Monol_5-6-yrs-old: $\chi^2=2.172$, $df=1$, $p=.141$; Bil_1 vs. Monol_6-7-yrs-old: $\chi^2=1.212$, $df=1$, $p=.271$; Bil_1 vs. Monol_7-8-yrs-old: $\chi^2=22.857$, $df=1$, $p=.000$; Bil_1 vs. Monol_adults: $\chi^2=33.409$, $df=1$, $p=.000$; Bil_2 vs. Monol_5-6-yrs-old: $\chi^2=12.063$, $df=1$, $p=.001$; Bil_2 vs. Monol_6-7-yrs-old: $\chi^2=.906$, $df=1$, $p=.341$; Bil_2 vs. Monol_7-8-yrs-old: $\chi^2=8.539$, $df=1$, $p=.003$; Bil_2 vs. Monol_adults: $\chi^2=16.681$, $df=1$, $p=.000$).

The between bilingual and monolingual group comparisons in the imperfective aspect condition for motion verbs suggest that Bil_1 matches with the preferences of Monol_5-6 yrs old group while Bil_2 with that of Monol_5-6 and Monol_6-7 yrs old groups (Bil_1 vs. Monol_5-6-yrs-old: $\chi^2=.586$, $df=1$, $p=.444$; Bil_1 vs. Monol_6-7-yrs-old: $\chi^2=4.881$, $df=1$, $p=.027$; Bil_1 vs. Monol_7-8-yrs-old: $\chi^2=17.252$, $df=1$, $p=.000$; Bil_1 vs. Monol_adults: $\chi^2=28.454$, $df=1$, $p=.000$; Bil_2 vs. Monol_5-6-yrs-old: $\chi^2=.039$, $df=1$, $p=.843$; Bil_2 vs. Monol_6-7-yrs-old: $\chi^2=1.600$, $df=1$, $p=.206$; Bil_2 vs. Monol_7-8-yrs-old: $\chi^2=10.909$, $df=1$, $p=.001$; Bil_2 vs. Monol_adults: $\chi^2=21.176$, $df=1$, $p=.000$).

To further examine whether activity and motion verbs are treated by bilinguals as different types of constructions in the comprehension of aspect, two-way group-independence chi-square tests were performed. These show that (a) Bil_1 interpret perfective aspect as telic in activity verbs but not in motion ones (Activity vs. Motion: $\chi^2=5.000$, $df=1$, $p=.025$), while Bil_2 do not treat the two verb types differently when they appear in perfective; and (b) in the imperfective condition both groups make a distinction between activity and motion verbs (Bil_1: $\chi^2=3.348$, $df=1$, $p=.067$; Bil_2: $\chi^2=5.000$, $df=1$, $p=.025$).

In the same comparisons, the monolingual data show that (a) the interpretation of perfective activity verbs as telic is more strongly preferred than that of perfective motion ones for all child groups leading to significantly different responses per verb type; and (b) in the imperfective condition no statistically significant difference is found for any group suggesting that the comprehension of imperfective aspect as atelic overrides the syntactic properties of activity and motion VPs. The adult data in the between verb type comparisons present a ceiling effect clearly indicating that the verb type is irrelevant to their preferred readings of (a)telicity (Kaltsa in prep.).

3.3 The Production Study

The production experiment examines the production of telicity in the bilingual grammar of young successive bilingual learners⁵.

3.3.1 Materials and Procedure

The materials designed for the comprehension task were used for the production task as well. The production task was administered one or two months later than the comprehension task. The participants were shown one video at a time presenting either the telic or atelic condition and a test question followed. The test question was not morphologically marked for aspect (10) and it included a time adverbial to indicate past reference. The task for the participant was to describe the event.

- (10) Τι έκανε χθες το παιδί;
 what do-PAST (Perf/Imp) yesterday the child
 ‘What did the child do yesterday?’

3.3.2 Results

The data analysis consisted in (a) filtering out utterances with verbs not morphologically marked as past or inappropriate verbs; (b) counting the preferred use of perfective aspectual verb forms with telic and atelic events; and (c) counting the preferred use of imperfective aspectual verb forms with telic or atelic events. The data was subcategorized per verb type for all conditions. The mean percentages of the aspect/complement-telicity matching per group are presented in Figures 5 to 8.

Activity and Telicity in L2 Greek

In activity events, the interaction of aspect (perfective vs. imperfective) and event type (telic vs. atelic) is significant for all groups (Bil_1: $\chi^2=5.940$, $df=1$, $p=.015$; Bil_2: $\chi^2=14.982$, $df=1$, $p=.000$; Monol_7-8-yrs-old: $\chi^2=4.821$, $df=1$, $p=.028$; Monol_8-9-yrs-old: $\chi^2=48.187$, $df=1$, $p=.000$; Monol_adults: $\chi^2=14.704$, $df=1$, $p=.000$).

Figure 5 presents the mean percentages for the use of perfective and imperfective in describing telic activity events.

Figure 5 Activity Telic Events

The data reported in Figure 5 show that the older bilingual group uses perfective forms to describe telic events, whereas the younger bilinguals don't show any preference. This observation was statistically supported by one-way-goodness-of-fit chi-square tests (Bil_2: $\chi^2=6.667$, $df=1$, $p=.010$).

⁵ We do not include the results from the 5-6 yr old monolinguals due to space limitations. Nevertheless this group shows no significant results in production of telic and atelic events with respect to aspectual forms used (Kaltsa in prep.)

The data of the control groups show that 7-8 yrs old monolingual children have a similar attitude to Bil_1 group, while older monolingual children and adults clearly prefer using perfective over imperfective aspect (Monol_8-9-yrs-old: $\chi^2 = 26.667$, $df = 1$, $p = .000$; Monol_adults: $\chi^2 = 8.067$, $df = 1$, $p = .005$).

Figure 6 presents the mean for the use of perfective and imperfective in describing atelic activity events.

Figure 6 Activity Atelic Events

The data reported in Figure 6 show that both bilinguals and monolinguals strongly prefer to use imperfective to describe atelic events with activity predicates. This observation was statistically supported by one-way-goodness-of-fit chi-square tests (Bil_1: $\chi^2 = 10.286$, $df = 1$, $p = .001$; Bil_2: $\chi^2 = 8.345$, $df = 1$, $p = .004$; Monol_7-8-yrs-old: $\chi^2 = 4.267$, $df = 1$, $p = .039$; Monol_8-9-yrs-old: $\chi^2 = 21.600$, $df = 1$, $p = .000$; Monol_adults: $\chi^2 = 6.667$, $df = 1$, $p = .010$).

Turning to the between bilingual group comparisons for activity verb production the Bil_2 group uses perfective aspect more than the Bil_1 group when describing a telic activity event (Bil_1 vs. Bil_2: $\chi^2 = 3.073$, $df = 1$, $p = .080$). Comparing bilingual with monolingual groups in the telic condition the use of aspect aligns bilingual performance with that of Monol_7-8 yrs old. Moreover, while Bil_1 group performs differently from the older monolingual children and adults, the older bilingual group differs from the older monolingual children but matches the adult performance (Bil_1 vs. Monol_8-9-yrs-old: $\chi^2 = 14.249$, $df = 1$, $p = .000$; Bil_1 vs. Monol_adults: $\chi^2 = 3.779$, $df = 1$, $p = .052$; Bil_2 vs. Monol_8-9-yrs-old: $\chi^2 = 4.444$, $df = 1$, $p = .035$). The groups are not differentiated to each other in the atelic condition.

Motion and Telicity in L2 Greek

In motion events, the interaction of aspect (perfective vs. imperfective) and event type (telic vs. atelic) is significant for both bilinguals and monolinguals (Bil_1: $\chi^2 = 15.267$, $df = 1$, $p = .000$; Bil_2: $\chi^2 = 31.706$, $df = 1$, $p = .000$; Monol_7-8-yrs-old: $\chi^2 = 4.596$, $df = 1$, $p = .032$; Monol_8-9-yrs-old: $\chi^2 = 15.983$, $df = 1$, $p = .000$; Monol_adults: $\chi^2 = 12.117$, $df = 1$, $p = .000$).

Figure 7 presents the mean percentages for the use of perfective and imperfective in describing telic motion events.

Figure 7 Motion Telic Events

The data reported in Figure 7 show that only the older bilingual group and the adults use perfective verb forms to describe telic motion events. All other groups perform at chance (Bil_2: $\chi^2 = 3.500$, $df = 1$, $p = .061$; Monol_adults: $\chi^2 = 3.267$, $df = 1$, $p = .071$).

Figure 8 presents the mean for the use of perfective and imperfective in describing atelic motion events.

Figure 8 Motion Atelic Events

The data reported in Figure 8 show that all groups significantly prefer to use imperfective with atelic motion events. This observation was statistically supported by one-way-goodness-of-fit chi-square tests (Bil_1: $\chi^2 = 29.491$, $df = 1$, $p = .000$; Bil_2: $\chi^2 = 33.618$, $df = 1$, $p = .000$; Monol_7-8-yrs-old: $\chi^2 = 17.067$, $df = 1$, $p = .000$; Monol_8-9-yrs-old: $\chi^2 = 24.067$, $df = 1$, $p = .000$; Monol_adults: $\chi^2 = 9.600$, $df = 1$, $p = .002$).

Turning to the comparisons between bilingual groups there is no significant difference found. The comparison between bilingual and monolingual groups reveal that in the telic condition the use of perfective aspect is strong only for the Bil_2 group while the other groups perform similarly ($\chi^2 = 5.035$, $df = 1$, $p = .025$). In the atelic condition, both bilingual groups differ from adults on aspect (Bil_1 vs. Monol_adults: $\chi^2 = 4.311$, $df = 1$, $p = .038$; Bil_2 vs. Monol_adults: $\chi^2 = 6.333$, $df = 1$, $p = .012$).

Comparing activity with motion events, (a) Monol_8-9-yr-old children use perfective aspect for telic activities but not for motion ones (Activity vs. Motion: $\chi^2 = 12.478$, $df = 1$, $p = .000$), while the rest of the groups show no difference per verb type; (b) in the atelic condition both bilingual groups use the

imperfective with motion verbs more than with activity ones, while monolinguals show no difference (Bil_1: $\chi^2 = 3.568$, $df = 1$, $p = .059$; Bil_2: $\chi^2 = 6.835$, $df = 1$, $p = .009$).

4. Discussion

The comprehension study shows that bilingual children map perfective aspect onto telic activities and imperfective aspect onto atelic motions. However, perfective motion VPs and imperfective activity VPs remain problematic for bilinguals. These results indicate that bilingual children's choices are mostly driven by the semantics of the verb, i.e. activity and motion while morphological aspect is basically a realisation of lexical aspect. Accordingly, a VP such as 'eat the apple' (accomplishment) is understood differently to a VP such as 'run in the kitchen' (activity) marked with perfective aspect. Turning to the production study, bilingual children seem to have difficulties with aspectual marking in Greek suggesting, as in the comprehension study, a priority of situation type over viewpoint/grammatical aspect.

SILL REVISITED: CONFIDENCE IN STRATEGY EFFECTIVENESS AND USE OF THE *BAR* IN DATACOLLECTING AND PROCESSING

Penelope Kambaki Vougioukli

Associate Professor of Linguistics

Department of Greek

Democritus University of Thrace

pekavou@helit.duth.gr

ABSTRACT

SILL questionnaire is taken by 110 first year students of Greek in an attempt to reveal and activate potential SILL might have but not identified and investigated so far. The two issues introduced concern (a) users' confidence whether their choice of a specific strategy is effective, and (b) an alternative statistical tool, the bar [01], inspired from the fuzzy theory, instead of Likert scales. The advantages of the bar on the part of the subjects is that they do not need to try to elaborate fine differences between different subdivisions; moreover, they have a completely free choice among infinite points on a line rather than a limited 3...5...9... etc of a Likert scale. The researchers, on the other hand, are given the initiative to decide how many divisions to use in each case and, even more so, to apply a follow-up processing with different subdivisions. Confidence indications reveal that our subjects seem to realise how strategies might but they do not make often use of some they consider important because of lack of instruction and time devoted to the actual application of strategies in classroom environment.

Keywords: strategy, SILL, bar, fuzzy, confidence, alternative, effectiveness

0. Introduction

Language learning strategies have created a great deal of controversy over the years since Rubin and Stern first introduced the concept to the second language literature in 1975, followed closely by Naiman et al. (1978). All those early researchers mainly focused on identifying lists of strategies; however, research on language learning strategies really flowered in the 1980's and early 1990's, the, so to say, 'golden period', during which focus was completely on the good learner's choice of language learning strategy and the factors that affect that choice, moving in this way emphasis to classification. It is then that Rubin (1981) classified strategies according to whether they are direct or indirect and O'Malley et al. (1985) divided them into cognitive, metacognitive or socioaffective categories. In 1990, Rebecca Oxford published her landmark book "Language Learning Strategies: What Every Teacher Should Know" which included the "Strategy Inventory for Language Learning" or "SILL", a questionnaire which has been used continually ever since. Then towards the end of the 90s, Andrew Cohen (1998) produced his book on strategies for learning and using a second language. Nevertheless, not much on strategy instruction was introduced, apart from O'Malley and Chamot's handbook (1990) as well as certain sporadic hints, leaving this important issue suspended and in the discretion of individual teachers, or, even worse, of individual learners.

In the years to follow, there was a loss of interest in language learning strategies, perhaps due to the lack of instruction methodology; however, as it happens with every idea or scientific method, recently an important number of new studies has started to appear and, more interestingly, there is a tendency identified among them concerning a prolific teaching orientation.

1. Research background

1.1 Definitions of learning strategies

O'Malley & Chamot (1990:1) define learning strategies as “the special thoughts or behaviors that individuals use to help them comprehend, learn or retain new information” while Oxford (1999: 518) as “specific actions, behaviours, steps or techniques that students use to improve their own progress in developing skills in a second or foreign language. These strategies can facilitate the internalization, storage, retrieval or use of the new language”. Cohen (1998: 4) maintains that “language learning and language use strategies can be defined as those processes which are consciously selected by learners and which may result in action taken to enhance the learning or use of a second or foreign language, through the storage, retention, recall, and application of information about that language”. More recently, Chamot (2005: 112) claims that “strategies are most often conscious and goal-driven especially in the beginning stages of tackling an unfamiliar language task. Once a learning strategy becomes familiar through repeated use, it may be used with some automaticity”.

The development of those definitions reveals researchers' attitudes towards strategy use instruction and the necessity of its incorporation in school curriculum.

1.2 Methods for identifying learning strategies: collecting and processing the data

Collecting and processing data is a rather tedious however extremely important stage of every scientific research. Chamot (2005: 113) and O'Malley & Chamot (1990: 85) give an exhaustive review on methods and research, including self-report procedures such as interviews, questionnaires, diaries and journals or think-aloud protocols, as well as advantages and drawbacks of each method. Such methods include *interviews*, *diaries* and *journals* where learners write personal observations about experiences they have had during the learning procedure, problems they have encountered and the way(s) they have solved them, or *think-aloud protocols* where learners are asked to perform a language task and then describe the way they completed it. Of course all of the above mentioned methods have their limitations, since learners do not always report truthfully either because they can't recall their thinking or they can't describe it in detail. It is, therefore, advisable to use more than one of the above methods when collecting data for strategy research.

However, the most frequently used method of data collection is through *questionnaires*, that is, by asking students to reflect and report on how they approach certain tasks on how they complete them. Questionnaires may be widely and often used nowadays in every piece of research, however qualities such as versatility, responsibility and simplicity of a questionnaire are crucial. Making full use of all previous research and observations, Oxford (1990) has developed her famous *Strategy Inventory of Language Learning (SILL)* which has ever since been widely used in relevant research worldwide.

Moreover, it is important to consider how the second important stage following that of collecting, namely that of data processing is dealt with. *Strategy Inventory of Language Learning (SILL)* as introduced by Oxford in 1990 has kept its reliability, validity, utility and, consequently, popularity among researchers for more than two decades. What the SILL questionnaire measures is the frequency with which a learner uses *memory*, *cognitive*, *comprehension*, *metacognitive*, *affective* and *socioaffective* language learning strategies, as described by Oxford (1990). More specifically, SILL is used to identify the level of strategy use (low, medium, high) for each strategy class and the statistical tool used to measure this frequency is the 5-grades Likert scale. Over the years almost every research all over the world uses this process in order to achieve comparable results. Nevertheless, I have the feeling that SILL has a lot more potential not yet investigated and identified and the same feeling must have other researchers, too. Hence, with present research I will try to introduce some new issues in my attempt to reveal some of the hidden potential SILL has.

1.3 Factors affecting choice of language learning strategies

Such factors include the *language being learned* (Chamot et al 1987, Politzer 1983), the relation of *language proficiency* with the selection of strategies and frequency of use (Griffiths 2003, Lan & Oxford 2003, Kantaridou 2004, Kazamia 2003), *age* (Peacock & Ho, 2003) and *motivation* (Gardner 1985, Kantaridou 2004, Oxford & Nyikos 1989 and Psaltou-Joycey 2003). There are also other factors such as *learning style*, *culture*, *language teaching methods*, *field of study/career orientation*,

beliefs and task requirements in instructional settings (Oxford & Nyikos 1989, Rubin 1975, Psaltou-Joycey 2008, Gavriilidou & Papanis 2010a & b, Gavriilidou & Psaltou-Joycey 2010).

Gender

As for *gender*, research evidence shows clearly a superiority of females who seem to use overall more strategies than males (Ehrman & Oxford 1989, Lan & Oxford 2003, Lee 2003, Oxford & Nyikos 1989, Peacock & Ho 2003, Politzer 1983, Sheorey 1999). Few studies (Tercanlioglu 2004, Tran 1988) have reported opposite results, while no significant differences in strategy use between the two genders is reported by Griffiths (2003) and Psaltou-Joycey (2008), when examining multinational and multicultural groups.

2. Purpose and rationale

2.1 Confidence

In SILL what the learners are asked to indicate is how often they use a strategy, i.e. frequency. However, I have the feeling that there is another important issue, not normally addressed in linguistic research, which concerns the learners' attitudes towards the specific strategy they claim they use, namely their confidence about the *effectiveness* of each specific strategy and to which extent. This parameter might prove to be very important in the language learning process as confidence is a basic ingredient of learners' strategic competence.

Confidence in association with communication strategies has been investigated by Kambakis-Vougiouklis (1990, 1992, 1995, 2001, 2002), by Intze (2011), Intze and Kambaki-Vougiouklis (2009), Intze & Mathioudakis (2009), Mathioudakis (2009), and Mathioudakis & Kambaki Vougioukli (2010). More specifically, Kambakis Vougiouklis (1990, 1992a, 1992b) asks from her subjects not only to guess pseudowords of Latin and/or Greek origin but also to specify how confident they have guessed right. She claims that successful reading does not simply involve use of processing strategies (in reading) but it might need to be reinforced by readers' *confidence* in the results of their strategy use. She continues emphasizing that confidence in one's strategic competence should play an important role, first in the guessing process, which is instant communication with the author (or the speaker) and then, in the long run, in actual learning from his/her own guesses and experience. The results showed a lot of inconsistencies between accuracy and confidence as well as differences concerning gender, with males overconfident and females more balanced in most cases, yet not in every case. She concludes that learners cannot make the best out of their guessing and continue to learn from guessing because they simply do not trust their guessing; consequently strategies must be taught. Similar results she gets (1995, 2001, 2002) with young learners of Greek from the ex-USSR. Intze (2010) in her work with second language learners' accuracy and confidence of guessing, associates the term with self concept (Shavelson, Hubner & Stanton, 1976) and her work concerns young high school Muslim, Turkish speaking pupils. Again she finds inconsistencies between the two factors and she also concludes that teaching strategy use is very important. Muti (2011) prefers to associate confidence with self-assessment and self-monitoring. Finally, in Mathioudakis (2009), Intze & Mathioudakis (2009) and Mathioudakis & Kambaki Vougioukli (2010), it is investigated the correlation of accuracy and confidence in guessing words from Kazantzakis' 'Odyssey', a very interesting approach of the difficult process of reading literature. The fact is that one cannot find enough references in international bibliography that uses the term confidence in any of the above mentioned perspectives. Nevertheless, as confidence might prove to be very important in every aspect of language learning process, I think that it is worth investigating it together with frequency in SILL questionnaire.

2.1.1 Confidence in SILL questionnaire

When a SILL questionnaire, as well as many other questionnaires, is used there develop some questions normally not tackled, at least to my knowledge. How familiar are the subjects of any research with certain strategies mentioned in the questionnaire? Are they sure they really employ a strategy they claim they do because they think it is effective or do they do so because they have heard the teacher or the peers mentioning it? Although one would assume that when they claim they use a strategy, they most possibly consider it effective, I have many reasons to believe, after a series of applications at different levels, that claiming they use a strategy does not necessarily mean that they

also consider it effective. However, as this has not yet been investigated, I think it is ethical to include it as a parameter and find out. Moreover, asking our subjects to express themselves in an extra, complementary parameter in each question, gives more time to the actual time of procession they have to devote to each question-choice of strategy in SILL and even some of them may finally modify their decision.

2.2 The bar [01]

The second issue introduced in this piece of research is a new statistical tool, that is *the bar* [01], inspired from the fuzzy theory, instead of Likert scales normally and almost catholically used in questionnaires and certainly in SILL.

More specifically, a bar [01], is suggested, where 0 represents the completely negative answer/attitude and 1 the completely positive answer/attitude:

0 _____ 1,

The issue of the bar has been investigated in a monograph by Π. Καμπάκη-Bougiouklí (2009) as well as in a number of papers (Kambaki Vougioukli P. and Vougiouklis Th., 2008; Kambaki Vougioukli et al, 2011 and Vougiouklis Th. and Kambaki Vougioukli P., 2011) in association with both the main stages identified in every piece of research, namely *the filling in of a questionnaire* and *the results processing*.

2.2.1 The filling in process

It concerns both the researcher(s) and the subjects; the former has to be as precise and expressive in what s/he expects from the subjects and the latter have to be able to come up to the researchers' expectations.

In order to elaborate our point let us take the following example from SILL questionnaire using the Likert scale.

How often do you use dictionaries?

Possible answers may be

0 = never, 1 = almost never, 2=sometimes, 3=often, 4=always

The steps to be taken by every subject, consciously or unconsciously, while filling in the questionnaire using the above mentioned Likert scale could be as follows:

(i) Make sure s/he understands the usually fine difference between grades; this process becomes really difficult in a foreign/second language environment where the researcher could be encountered with the issue of insufficient linguistic knowledge, especially with the least sophisticated subjects. Moreover, we may be dealing with subjects who

And

(ii) Make up his/her mind which choice to go for. Not an easy job at all. If the scale has a medium the majority of the subjects will probably go for it. Let alone the fact that quite a few possible choices such as 'quite often' are not included in this specific scale.

Now, let us take *the bar* [01] suggested

0 _____ 1

This time the subject can cut the bar at any point -actually infinite- s/he thinks expresses his/her attitude towards any item, at the specific moment without spending valuable time as to what each different rating means in order to decide.

0//////////1

At this point it is important to clarify that the length of the bar should be kept standard for comparisons. After a lot of applications and a lot of thought, we decided to replace the 10cm long line we had initially chosen and applied quite a few times, with the Golden Ratio of 10, i.e. 6.2. This was

done completely consciously as we found out that subjects are not familiar with this length as they were with 10 and consequently their responses were more spontaneous.

Advantages of the bar as compared to Likert scales in the filling in stage

The main advantage of the bar as compared to the classic scale on the part of the subjects is that they do not need to try and make distinction between different subdivisions, not always clear such as *good*, *quite good* and *good enough*, removing in this way a burden from the researchers who will not spend time and effort to explain fine linguistic differences to their subjects, especially the less sophisticated ones. Even more so such explanations are not necessarily objective and widely accepted. Moreover, the subject is given the initiative to make a completely free choice rather than the pre-decided ones. Actually his/her choices are infinite as any point on the continuum may represent his/her option the specific moment.

2.2.2 Results processing

The processing of the data stage mainly concerns the researcher(s). It is very important for them to have the ability to derive as much information as possible. Collecting data is a demanding process and sometimes it is wasted in only one processing. I strongly believe that there is more valuable information hidden and should be revealed and fully exploited rather left aside.

Advantages of the bar as compared to Likert scales in the results processing

The use of the bar might release some of hidden abilities/possibilities not yet being identified in SILL. More specifically, when using a Likert scale, you must decide in advance how many divisions you will use. By contrast, when using the bar, you do not have to decide from the beginning. Moreover, the same data can be processed using different subdivisions, for a number of reasons including that of comparability with different researches.

To recap, versatility of the bar gives the researchers the initiative to decide how many subdivisions will be finally used rather than the non-flexible pre-decided ones: three, four, five etc of the usual Likert scales. Subsequently, a questionnaire filled-in using a bar could be processed more than once in case the researcher may wish to make it comparable with some other researcher's work where different subdivisions have been used saving in this way time and effort.

2.3 Purpose of present research

With present research an attempt is made to reveal and activate potential a tool like SILL might have and not identified and investigated so far. If the presence of such potential is considerable, perhaps a new series of applications of SILL might follow.

In present research it is investigated:

(1) How frequently our subjects use learning strategies, (2) how confident they feel with each choice/how effective they consider each strategy, (3) what is the correlation between *frequency* and *confidence / effectiveness*, (4) what are gender differences, if any, in both variables as well as their correlations.

3. Method

3.1 Subjects

110 first year students of the Department of Greek in Komotini , equal numbers of males and females, participated. They were all volunteers and they were offered some kind of bonus for participating and filling in the questionnaire carefully and consciously.

3.2 Task(s) / Procedure

Our subjects were instructed to fill in the SILL questionnaire in Greek as well as using the bar instead of the Likert scale. Although the use of the bar was something completely new to them they seemed to understand it straight away. Their attention was also drawn to the fact that not only did they have to

indicate how often they use a strategy but also how confident they feel with each of them, or, in other words, how effective they thought each strategy is. It was this specific moment that students reacted claiming that often use implies effectiveness. They were told that this might be true or not true and anyway it was an issue to be investigated as there are cases when we may use a strategy often but we are not very confident about its value. However, we go on using it either because we are used to it or because there is not another alternative at our disposal. On the other hand, there might be cases when students might wish they knew how to make a better use of a specific strategy they realise might be effective under specific circumstances but they do not know how. They seemed to be satisfied with explanations.

All subjects filled in the complete questionnaires (an example with the two tasks required from the subjects can be found in appendix II).

4. Analysis

As it is one of the first applications of the bar with SILL and in order to make results comparable to previous research, after the test was completed the bar indications were converted into the 5/grade Likert scale normally used in SILL for all those years all over the world. However, one should keep in mind that a lot of more analyses with different degradation can be and will be done in order to observe differences occurring from different conventions.

The statistical analysis was on the SPSS computing package by a professional statistician.

5. Results

5.1 Reliability

The general Cronbach's Alpha was .917 for frequency and .913 for confidence; however, item 3, namely the compensation strategies, appears too low and this affects the total reliability of the test.

Cronbach's Alpha

	Frequency	Confidence
General	.917	.913
Memory	.654	.677
Cognitive	.821	.799
Compensation	.456*	.714
Metacognitive	.733	.714
Affective	.662	.625
Social	.791	.764

It is difficult to assign it to any reason such as problematic translation, or learners' fatigue at this stage as it needs extra investigation, even more so as confidence for compensation strategies is .714, i.e. it does not seem to have the weakness of frequency.

5.2 Results /discussion

In the appendix I at the end, there is a complete exhibition of the results of this research.

As for our research questions as posed in 2.3 above, let us start with Tables 1 and 2 as in the Appendix, which tackle the first three questions namely (1) *how frequently our subjects use learning strategies*, (2) *how confident they feel with each choice*, and (3) *what is the correlation between frequency and confidence / effectiveness*. In tables 1 and 2 there are presented the values of the correlation between the variables, different strategies, which cross among themselves horizontally and vertically. Both single asterisk $p < 0.05$ and double asterisk $p < 0.01$ imply quite safely that the

experimental findings could be valid for the general population-double asterisk indicating higher possibility. Now, let us attempt an interpretation of the results trying to see the correlations between different strategies. For example, let us take memory and cognitive strategies. Do subjects who report high –or low- frequency in one do the same for the other? Here, the answer cannot simply be a ‘yes’ or a ‘no’ but how strong this correlation is. Generally, the correlation indicator takes values from +1 to -1. When it is exactly +1 or -1, then we can call it the perfect correlation between the strategies examined. In our case of memory and cognitive strategies is +.67**, i.e. highly positive and away from +1. This might possibly mean that subjects who report high frequency of use of memory strategies also report high use of cognitive ones. Moreover, this correlation was $p=0.01$, which allows us to generalize quite safely, too. Similar are the results in most cases apart from the correlation between compensation and metacognitive strategies .15, i.e. there not an asterisk and the value indicator is very close to 0, i.e. complete absence of correlation. This inconsistency with compensation strategies, which was also identified in Cronbach’s Alpha and in the rest of our results, needs further investigation. Question (3), now, namely *what is the correlation between frequency and confidence / effectiveness*, as shown in Table 3 (here the correlations are difference rather than analogy): let us take for example males and females with memory strategies. Here there is a statistically significant difference $p=.043$, the Frequency Mean is 2.02 and the Confidence Mean 2.16. This could be interpreted as a tendency among subjects to consider this strategy effective and feel confident with it; nevertheless their use of it is less frequent than their confidence in absolute numbers. Fairly enough, one might comment that still the difference between 2.02 and 2.16 is too small. However, as this result occurs in every strategy, it needs further investigation as it might imply that learners cannot make the best out of each strategy. The only inconsistency is identified with the compensation strategies, as expected from the Cronbach alpha. Furthermore, as this is only a pilot study, it will take some more applications to reach clearer conclusions.

With the final question (4) now, *what are gender differences, if any, in both variables as well as their correlations*, similar observations could be made. In table 6, about frequency, there are some statistically significant differences between males and females in memory, $p=.247$, compensation, $p=.141$, and affective, $p=.228$, with females’ means higher than those of the males. Similarly, in table 7, about confidence, we have memory, $p=.066$, compensation.190 and effective, $p=.113$; again females’ means are higher than those of the males, which implies that females are more aware of the effectiveness of a strategy. Females seem to be more skilful with strategy use than males as found in previous research (e.g. Ehrman & Oxford 1989, Green & Oxford 1995, see 1.3); moreover, they also seem to be more confident than males or at least, they seem to be confident when frequent. This result is compatible with our results with female students (see Kambaki 1992a) but not compatible with ex-USSR children or Muslim, Turkish speaking ones, where males seem to be more confident than females. However, only an indicating rather than a direct comparison can be made as not all variables coincide.

There are a lot of interesting findings one could easily locate by looking at the tables. However, as four were the main points to be addressed here and, anyway, space is limited, the rest must be left for future elaboration.

Apparently, the main conclusion derived from this experiment might be that learners seem to have realised how important the use of strategy in the process of language learning might prove to be –and this is proved by their confidence – but they do not make frequent use for a number of reasons the most important being lack of instruction and lack of time devoted to the actual application of strategies in classroom environment. Other reasons may be unwillingness and lack of time again on the part of the learners. Nevertheless, it is only a pilot study and it will take more applications and more elaboration as it is suggested in 6 below.

6. Teaching implications/ further research

As for the main teaching implication, this might be once again that strategies can and must be taught. This is implied by our subjects’ indication of higher confidence than frequency in memory and cognitive strategies, which, as interpreted above, might be due to the fact that they do not know how to use these strategies, although they seem to be aware of their effectiveness, or at least, to suspect they might be effective. Something that could be done about it, in the future, could be either to have oral or written interviews with our subjects, asking them to elaborate on their choice. Such a procedure requires quick processing of the data, so that the subjects still have the picture of their answers which anyway are spontaneous and due to change; and anyway this type of problems is tackled in every research and cannot have a radical solution as it concerns human attitudes. All in all strategy

instruction, as mentioned in 1.4 above, has not been widely researched, the main reason probably being the longitudinal nature of such research which involves a lot of factors to be controlled.

Moreover, as present research is the first conducted with the specific design, actually a pilot study, the results are not and cannot be completely reliable; however they show a tendency which has to be further investigated with more subjects from different levels and ages. Moreover, it is interesting to apply follow up processing, with different subdivisions and see if there are statistically significant differences of any kind not identified in the original 5/point choice. This is the potential offered by the bar and it has to be exploited thoroughly. Finally and once again, present attempt is not to question the importance and validity of the actual questionnaire, which is undoubted, but to try alternative conventions in order to reveal new potentials, new uses of the SILL or any other questionnaire, a rather ecological action.

THE TEMPORAL STRUCTURE OF NARRATIVES IN SECOND LANGUAGE ACQUISITION OF GREEK

Vicky Kantzou

University of Athens, Greece
Institute for Language and Speech Processing / R.C. “Athena”
vickykantzou@hotmail.com

ABSTRACT

This paper focuses on the development of narrative skills in the acquisition of Greek as a second language. It investigates the means for expressing two types of temporal relations, sequence and simultaneity. Beginning, intermediate and advanced Albanian learners of L2 Greek were asked to tell a story based on a silent animated film. The analysis revealed that marking of temporal sequence appeared earlier than marking of simultaneity. Beginners relied upon lexical aspect to advance narrative time, at least when their vocabulary allowed them to, while intermediate learners mainly used past perfective verb forms and temporal adverbs. Advanced learners made use of the lexical aspect of eventualities as well as of inflectional morphology. Simultaneity was marked by employing a variety of means, but often ineffectively at both the beginning and the intermediate level.

Keywords: second language acquisition, narrative, temporality

1. Introduction

The expression of temporality by adult second language (L2) learners has attracted a lot of attention in the literature. The relevant research has largely focused on the emergence of verbal morphology of tense and aspect and on factors determining their acquisition (Bardovi-Harlig 2000, Salaberry and Shirai 2002). However, since the '80s a methodological starting point for research has not been morphology, but a conceptual domain like space or time. Within this “function to form” approach, researchers try to identify which sub-components of such domains are expressed at each stage of language acquisition and by what means (von Stutterheim and Klein 1987, Bardovi-Harlig 2000, Starren 2001). This approach has made it possible to gain some insight into the structure of learners’ language systems even before the emergence of morphology. Moreover, it turned researchers’ attention toward discourse, since principles of discourse organization carry a significant part of temporal information (Klein, Dietrich and Noyau 1993).

Previous research has shown that even learners at a beginning level are able to express temporal information. More specifically, before the emergence of morphology, speakers rely on lexical means (adverbs, noun phrases) and the cooperation of their interlocutor to temporally locate an event as well and on discourse principles to express basic temporal relations between events (Klein and Perdue 1997). Gradually morphology emerges and learners’ linguistic repertoire is enriched. Since research on the development of temporality has mainly focused on early and quite advanced levels of L2 acquisition, little is known about temporal organization of texts at intermediate level. Moreover, not much research has been conducted on the temporal organization in L2 Greek at various levels of proficiency.

In this context, this study focuses on the expression of temporal relations in discourse, more particularly oral narrative texts at three levels of L2 competence in Greek: beginning, intermediate and advanced. We focus upon two types of relations between events: sequence, which is the basic temporal relation in narratives, and simultaneity. The more specific questions we raise are:

- At which level of L2 competence are these two temporal relations expressed?
- What are the means used for this purpose?

A narrative, according to some scholars, comprises two information levels, the foreground and the background. There is, however, no consensus on the characteristics attributed to each of them (Hopper 1979, Hopper and Thomson 1980, Reinhart 1984). We here follow Klein and von Stutterheim (1989), who argue that all texts are organized around a central question, which in the case of narratives is

“what happened next?”. Utterances responding directly to this question form the foreground. Utterances answering secondary questions, for example “how did the protagonist feel?”, form the background.

In Klein and von Stutterheim's framework (1989), foregrounded utterances have two basic characteristics. First, they denote eventualities¹ with a time boundary and they entail a change of state. Second, they promote narrative time. More specifically, the reference time of the first event is introduced by an adverb or follows from the situational context. Subsequent utterances are anchored to that event in a relation of temporal sequence (Klein 1995). This is what Klein and von Stutterheim call “the principle of natural order”, according to which the order of events in discourse reflects the order they actually happened. Thus, narrated events are not individually anchored to the *here and now* of the speaker, but one is anchored to the other, forming a referential chain. Speakers are free to anchor their narratives in present, past or even future tense or shift between tenses. However, the anchor tense changes the mental vantage point from where the narrator chooses to “watch” the narrated events, with past being the neutral viewpoint while present or future suggests a more subjective evaluation of events (Tzevelekou and Kantzou 2011). As for tense shifts, Schiffirin (1981) and Wolfson (1982) argue that they are not incidental, but are used to mark discourse units. Moreover, shifts to the so-called “historical present” highlight escalation points of the story.

In Greek the time boundary necessary for advancing narrative time is expressed through perfective aspect, whenever past tense is used. In case the narrative or a passage is anchored to the present tense, time is promoted through lexical aspect, as the perfective/imperfective opposition is unavailable in this tense. More specifically, the inherent completion point of accomplishments and achievements is taken as an anchor point for the next event (Tzevelekou, in print). Moreover, aspectual verbs focus on the beginning or end of an activity. Adverbials of temporal sequence are also used to mark sequence of events. Breaking the principal of natural order in cases of eventualities with inherent completion points requires marking of the temporal relation, through temporal clauses for example.

2. Method

Narratives were elicited from three groups of L2 learners of Greek: beginner ($n=9$), intermediate ($n=15$) and advanced ($n=15$). All learners had Albanian as their L1. The elicitation material was a silent animated film, which describes the adventures of a boy and his dog during a winter day. Narratives were transcribed and divided into propositions, which were further categorized as foreground or background. Foregrounded propositions were coded for lexical aspect, tense, aspectual verbs and adverbs of temporal sequence. Temporal sequence was studied for all foregrounded events in each narrative. Simultaneity, on the other hand, was studied in relation to specific overlapping events of the film (Picture 1). For those learners that made an effort to denote this temporal relation, the means used were coded (e.g. temporal clauses, aspect, adverbials).

Picture 1 Screenshots from the overlapping events of the film

The proficiency level of the L2 learners was determined on the basis of criteria proposed by Varlokosta and Triandafyllidou (2003). These criteria are presented in Table 1².

¹ Following Bach (1981), the word “eventualities” is used as a general term to refer to all types of lexical aspect.

² The proficiency level was determined on the basis of a speech sample larger than the narrative studied here (for details, see Kantzou 2010).

	NOUN PHRASE	VERB PHRASE	CLAUSES
BEGINNING	❖ Lack of genitive morphological marking	❖ Perfective non-past forms in main clauses (subjunctive) ❖ Lack of Past Imperfective	❖ Lack of indirect speech
INTERMEDIATE	❖ Genitive in singular number (occasional production of plural genitive)	❖ Past Imperfective ❖ Present Perfect ❖ Occasional production of Past Perfect	❖ Lack of indirect speech
ADVANCED	❖ Genitive in both singular and plural	❖ Stabilization of Past Perfect ❖ Functional differentiation of verb stems (perfective – imperfective)	❖ Indirect speech ❖ Reason clauses introduced by <i>αφού</i> ('after') ❖ Concessive clauses

Table 1 Criteria for defining L2 proficiency level

3. Results

Table 2 presents the number of propositions and the percentage of foregrounded and backgrounded ones in each group of learners. Beginners produced short narratives, with a statistically significant increase at the intermediate level (Mann-Whitney U test, $p\text{-value}=0,015<0,05$), but not at the advanced level, although a rise in total number of propositions was observed (Mann-Whitney U test, $p\text{-value}=0,539 > 0,05$). The percentage of foregrounded propositions in all groups was higher than that of backgrounded ones.

	Total number of propositions	Foreground	Background
Beginning	222	52,70%	46,85%
Intermediate	768	55,60%	44,40%
Advanced	854	57,85%	42,15%

Table 2 Total number of propositions and percentages of foreground and background propositions

Figure 1 shows the use of tenses in the foregrounded propositions, regardless of the inherent temporal properties of eventualities. Beginners equally used past and non past forms. They also produced a large number of non-past perfective verb forms, imperatives, past participles and other forms that are considered infelicitous choices. Intermediate learners on the other hand came to restrict themselves mainly to past tense. At the same time, present tense and infelicitous verbal choices were reduced. At the advanced level present tense propositions tripled in frequency. However, statistical analysis of these results revealed a significant difference between past and non-past forms only within the intermediate group (Wilcoxon test, $Z=-2,175$, $p\text{-value}=0,030 < 0,05$), but no difference within the advanced group ($Z=-1,264$, $p\text{-value}=0,206 > 0,05$).

Figure 1 Use of verbal forms in foregrounded propositions

Adverbs of temporal sequence appeared in about 13 and 16% of all propositions in beginning and intermediate learners, but dropped to about 5% at advanced level (Table 3). Statistical analysis confirmed that the group of advanced learners differed significantly from the other two groups (Mann-Whitney U test, Beginning–Intermediate $p\text{-value} = 0,599 > 0,05$, Beginning–Advanced, $p\text{-value} = 0,005 < 0,05$, Intermediate – Advanced $p\text{-value} = 0,002 < 0,05$).

L2 learners	Percentage
Beginning	15,77%
Intermediate	13,28%
Advanced	5,27%

Table 3 Percentage of propositions containing an adverb of temporal sequence

Turning now to each learners' group separately, we will examine in more detail the way they constructed the foreground of their narratives and their attempts to indicate a violation in the "principle of natural order".

3.1 Beginning level

Although it is difficult to claim that there was no functional morphology at the beginning level, it seemed that it was not sufficiently developed to systematically support the advancement of narrative time. As shown in Table 4, beginners did not systematically use perfective aspect (Aorist) in foregrounded propositions. Several verbal forms were used infelicitously (ex. 1–2). Given these difficulties with verbal morphology, other means had to be exploited for temporal relations to be expressed.

	Eventualities <u>with</u> an inherent endpoint	Eventualities <u>without</u> an inherent endpoint
Past Perfective (Aorist)	33,33%	2,57%
Present	27,35%	11,11%
Past Imperfective	0	0
Aspectual verb – Past tense ³	0	0
Aspectual verb – Present tense	0	0,85%
Perfective, non-past forms	15,38%	0,85%
Other forms (verbal or not)	8,56%	

Table 4 Tenses and aspectual verbs in the foregrounded propositions of beginning learners

³ In the case of aspectual verbs, the inherent temporal characteristics refer not to the aspectual verb itself – which is always *telic* – but to the temporal properties of their complements.

- 1) *Μετά ο αφεντικό πάει, πίνει ένα τσάι και &εϋκα &εϋκαριστ ευκαριστημένη xx το σκύλος.*⁴
Then the [dog's] master goes, drinks a cup of tea and happy [: PASSIVE PARTICIPLE] the dog.
- 2) *Το σκύλο πάει [//] πήρε ένα από τα πάτινα και θα βάλει μέσα στο [//] στο πόδι της και φύγει να κάνει πατιναζ ο σκύλος.*
The dog goes [//] took one of the skating shoes and will put [: PERFECTIVE FUTURE] inside her foot and leave [: PERFECTIVE NON-PAST] to skate the dog.

Within the beginning level two phases were identified. In the first phase, learners used very limited grammatical and lexical resources. Narratives were very brief, mainly consisting of backgrounded propositions where high frequency verbs such as *είμαι* ('to be') predominated. The difficulty of constructing chains of sequential events stemmed less from limited morphological and lexical devices denoting time and more from a limited vocabulary for describing the events themselves. In example 3 the proposition *είναι μέσα στο νερό* ('they are in the water') is a state, which takes the place of an event, something like *έπεσε μέσα στα νερό* ('fell in the water'), because the speaker has not yet acquired the verb *πέφτω* ('fall') (or it was not available to her at the time of speaking).

- 3) *Είναι ένα παιδί και θέλει να ## ice [% in english] # και # η σκύλο θέλει και έρθει [?] και δεν μπορεί γιατί δεν έχει παπούτσι. Ε: μετά ## ε: <ο παι> [//] τα παιδιά είναι στο [//] μέσα στο νερό και η σκύλο θέλει να +... to get out [% in english].*
There is a boy and he wants to ## ice [% in english] and the dog wants and come and [he] cannot because he doesn't have a shoe. E: then ## e: <the ch> [//] the children are in the water and the dog wants to +... to get out [% in english].

In the more advanced phase of beginners, vocabulary was enriched and more events were included in the narratives. Although there were some verbal morphological contrasts, tense and aspect morphology was not systematically used to mark temporal relations. Sequence was instead mainly expressed through the inherent completion point of events. Learners were thus able to structure simple narratives consisting of foregrounded events and backgrounded states (ex. 4). However, as in the first phase, there were cases indicating that learners still faced difficulties constructing eventualities with appropriate inherent temporal characteristics (see double underlined proposition in ex. 6 below). Especially in the second phase, adverbs of temporal sequence became very important for learners, since they contributed to clarifying temporal relations (Bardovi-Harlig 2000, 39).

4) Foreground

[b] *και ξυπνήσει το πρωί*
and wake up in the morning
[c] *και κάνει τη γυμναστική το πρωί.*
and exercises in the morning.

[h] *&α εεε πάει στο σπίτι στο [//] μμμμ στο αγκόρι*
(he) goes to the house to [//] to the boy
[i] *και χτυπήσει την πόρτα.*
and knock on the door.

Background

[a] *τόρα ήταν μια [//] ένας σκυλός*
Now there was a dog

[d] *Αλλά ήταν [//] το καιρό ήταν κακό,*
but the weather was bad
[e] *ήταν πολύ κρύο,*
it was very cold
[f] *<το δρόμος xxx> [//] οι δρόμοι ήταν παγωμένοι.*
the road xxx> [//] the roads were frozen
[g] *και αυτό <δεν xxx> [//] δεν μπορεί να περπατεί.*
and he can't walk

⁴ The transcription in the examples has been done in the Greek alphabet, using the symbols proposed in the Childes transcription system (MacWhinney 2012).

[j] *Μετά αυτός πάει έξω*
Then he goes out
[k] *και είδε το δρόμο*
and saw the road

[l] *που &ήτ ήταν παγωμένο.*
that was frozen.

Despite its effectiveness, the beginners' language system was characterized by two significant weaknesses. The first was that lack of systematic aspect marking made it difficult to integrate eventualities without an inherent completion point into the foreground. The second became apparent in cases where learners needed to break the "principle of natural order" to denote temporal relations like simultaneity or anteriority between dynamic events. In fact, none of the first phase beginners marked the case of simultaneity studied here, while two of the second phase made an unsuccessful effort (ex. 4-5).

- 5) *Το αγόρι όταν παίζουν μαζί, το αγόρι έσπασε το πάγο και ε: xx μπει μέσα.*
The boy fall, when [they] play [: PERFECTIVE NON-PAST] together, the boy broke the ice and e: xx fall in.
- 6) *Αλλά μετά το αγόρι πήρες τη πάτινα το σκυλό και συνεχίζει να κάνει μόνο του, αλλά το πάγο δεν ήταν πολύ καλό και το παιδί μπήκε μέσα στο νερό.*
But then the boy took the skating shoe and continues [: PRESENT] to skate alone, but the ice was not very good and the boy went into the water.

3.2 Intermediate level

As mentioned, learners in this group preferred past tense propositions (71.12% of all foregrounded ones), while the present tense was restricted to 24.65% (Table 5). Past and present verb forms were not uniformly distributed among all narratives. The majority of speakers produced past anchored foregrounds. However, three of them anchored their foreground mainly in the present tense (Figure 2).

	Eventualities <u>with</u> an inherent endpoint	Eventualities <u>without</u> an inherent endpoint
Past Perfective	57,61%	4,92%
Present	19,91%	3,51%
Past Imperfective	2,34%	2,11%
Aspectual verb – Past tense	0%	3,98%
Aspectual verb – Present tense	0,47%	0,23%
Perfective, non-past forms	4,22%	0%
Other forms (verbal or not)	0,70%	

Table 5 Tenses and aspectual verbs in the foregrounded propositions of intermediate learners

Figure 2 Temporal anchoring of the foreground in the narratives of intermediate learners (n=15)

In the past anchored propositions, temporal sequence was effectively expressed, since the Past Perfective was more systematically used to mark it (ex. 7). In the case of present tense propositions, the inherent completion point of events also advanced narrative time (ex. 8).

- 7) *Μετά ο σκύλο είπε ότι κάνει κρύο και έβαλε τα χέρια του πάνω του και ο άνθρωπος πήγε μέσα και έφερε ρούχα για το σκύλο.*
Then the dog said [: PERFECTIVE PAST] that it was cold and put [: PERFECTIVE PAST] his hands around him and the man went [: PERFECTIVE PAST] inside and brought [: PERFECTIVE PAST] clothes for the dog.
- 8) *Και πάει στην άκρη <της καλ> [//] της σκάλας, βγάζει το κασκόλ του και του το δίνει.*
And [the dog] goes [: PRESENT] to the edge of the ladder, takes off [: PRESENT] his scarf and gives [: PRESENT] it to him.

However, there was evidence in intermediate narratives that learners faced some problems when expressing this temporal relation. Two sources of difficulty were identified. First, verbal morphology of tense and aspect was not fully developed, as the infelicitous uses of the past imperfective and other verb forms indicated in about 9% of all foregrounded propositions (ex. 9-10). Second, learners were not always able to formulate propositions with appropriate to context inherent temporal characteristics. This created vagueness especially in present tense propositions. In example 11 the verb *σκέφτομαι* ('think') seems to stand in the place of a verb with an inherent completion point like *αποφασίζω* ('decide'). The frequent use of aspectual verbs by this group is an indication, in our view, of the effort to integrate eventualities without an inherent completion point into the foreground (ex. 11).

- 9) *και μετά χτύπησε το κουδούνι του αφεντικό και +... [...] και μετά φορούσαν τα ρούχα τους και βγήκανε για βόλτα.*
And then (he) rang its master's doorbell and... and then they were wearing [: PAST IMPERFECTIVE] their clothes and went out for a walk.
- 10) *xx ο άνθρωπος &επε πέφτε κάτω. Μετά ο άνθρωπος πήρε κάτι...*
xx the man fall [: IMPERFECTIVE IMPERATIVE?]. Then the man took something...
- 11) *Ζήτησε βοήθεια από το σκυλάκι, <σκυλάκι εεεε> [/] σκυλάκι εεεε: αρχίζει να γελάει хахаха хахаха xx σκυλάκι, και μετά σκέφτεται, λέω [/] λέω εγώ, να τον βοηθάει, πήρε μια σκάλα...*
He asked the doggy for help, doggy e: [/] doggy e: starts to laugh hahaha hahaha xx doggy, and then [he] thinks, I say, to help him, [he] took a ladder...

As mentioned, intermediate learners made substantial use of adverbs, even though temporal sequence was often simultaneously marked by additional means in the same proposition (e.g. the past perfective) (ex. 12).

- 12) *εε και μετά αυτά που είχε φορέσει ο σκύλος <τα πήρε> [//] τα φόρεσε το αγόρι, και μετά [...] άρχισε αυτό να κάνει σκι . Επίσης εεε μετά νομίζω ότι βούλιαξε ο [//] το αγόρι , βούλιαξε μέσα στο ποτάμι...*
and then the boy took [//] put on those [: the skate shoes] that the dog had put on, and then [...] he started to skate. Moreover, then I think that the boy sank, sank into the river...

One of the major weaknesses of beginners' language system, namely the expression of simultaneity, remained a source of difficulty at the intermediate level. Only half of the learners attempted to mark it, and, in fact, not always successfully, as learners faced difficulties in the lexical encoding of events, the use of Past Imperfective and the lack of specialized temporal conjunctions. In example 13, use of the general conjunction *όταν* ('when') with the light verb *κάνω* ('do'), which does not present an opposition between perfective and imperfective stem, does not make clear whether the activity of skating was completed or not. In example 14, the speaker implicates through the aspectual verb *αρχίζω* ('start') – although not in the appropriate aspect – that the activity of skating may not have been completed (Papafragou 2006), but this implicature is not further developed and the event of the ice breaking is not mentioned.

- 13) *Και μετά γύρισε και μπήκε το παιδί μέσα και όταν [//] όταν έκανε το γύρο του πάγο # ε: άνοιξε [//] με τις παπούτσες άνοιξε μια τρύπα που [//] που μπήκε μέσα.*

And then he [: the dog] returned and the child went on the lake and when he did a round in the lake, he opened a hole with his shoes, into which he fell.

- 14) Μετά ο [/] ο άνθρωπος άρχιζε να κάνει πατινάζ και ο [/] μπήκε μέσα στο νερό γιατί εκεί που πήγε αυτός <ο πάγος δεν ήταν> [/] δεν υπήρχε πολύ πάγο κι αυτός πήγε μέσα στο νερό.

Then the man started [: PAST IMPERFECTIVE] to skate and the [/] went into the water, because where he went <the ice was not> [/] there was not much ice and he went into the water.

3.3 Advanced level

Within the advanced group, individual differences were observed with regard to foreground anchoring (Figure 3). The majority of learners showed a preference for present tense. However, three learners used past tense in the foreground, while two used both present and past tense roughly equally.

Figure 3 Temporal anchoring of the foreground in the narratives of advanced learners (n=15)

As shown in Table 6, advanced learners effectively moved narrative time forward using either past perfective marking (ex. 15) or the inherent completion point of events in case of present tense anchoring (ex. 16).

	Eventualities <u>with</u> an inherent endpoint	Eventualities <u>without</u> an inherent endpoint
Past Perfective	20,65%	2,23%
Present	63,77%	6,88%
Past Imperfective	0,81%	1,22%
Aspectual verb – Past tense	0,40%	0,40%
Aspectual verb – Present tense	0,61%	2,23%
Perfective, non-past forms	0,40%	0%
Other forms (verbal or not)	0,40%	

Table 6 Tenses and aspectual verbs in the foregrounded propositions of advanced learners

- 15) Πήρε τα πατίνια του το αγοράκι, ντύθηκε και εκείνος ωραία και πήγανε σε μια λιμνούλα που ήταν λίγο πιο πέρα.

The little boy took [: PERFECTIVE PAST] the skating shoes, he also got dressed [: PERFECTIVE PAST] nicely and they went [: PERFECTIVE PAST] to the pond that was just beyond.

- 16) *Μπαίνει μέσα στη λίμνη και ξαφνικά, ενώ χοροπηδούσε εκεί μέσα [...] ο πάγος σπάει και ανοίγεται μια τρύπα, στην οποία πέφτει μέσα το παιδί. Και αρχίζει να φωνάζει τρομαγμένο.*
 He goes [: PRESENT] into the lake and suddenly, while jumping in there [...], the ice breaks [: PRESENT] and a hole is opened [: PRESENT], into which the boy falls [: PRESENT]. And [the boy] starts [: PRESENT] to cry terrified.

Vagueness in temporal sequence was reduced to a minimum. Cases of vagueness mainly regarded present tense propositions in which speakers made infelicitous choices of vocabulary. In example 17, the learner uses the verb *περπατάω* ('walk'), resulting thus in an eventuality without an inherent completion point. The use of a verb like *ανεβαίνω* ('climb') would have removed the vagueness.

- 17) *Παίρνει μια σκάλα που ήτανε σ' ένα δένδρο εκεί και το βάζει, περπατάει πάνω στη σκάλα, βγάζει το κασκόλ του ο σκύλος...*
 It [: the dog] takes a ladder that was at a tree over there and it places it, walks [: PRESENT] on the ladder, the dog takes off its scarf...

Adverbs of temporal sequence were reduced in comparison with intermediate level learners. Moreover, at this level they were used, not only to express a temporal relation, but they also undertake a discourse function, appearing in places of discontinuities in narrative content, like place or character shifts (ex. 18).

- 18) *Και έκανε πατινάζ ο πρώτος σκύλος και γύρισε πάλι πίσω. Μετά # πήρε το παπούτσι στο σκύλο ο αγοράκι.*
 And the first dog skated [: the dog skated first] and came back. Then the boy took the shoe from the dog.

Finally, advanced learners came to mark simultaneity between dynamic eventualities, through various devices: aspectual verbs to implicate that an activity did not end, temporal clauses, imperfective marking and adverbials (see ex. 16 above).

4. Discussion

In summary, temporal sequence between events was marked earlier than simultaneity. Moreover, the particular means used for marking temporal relations differed rather interestingly across the three levels of L2 competence. While beginners relied mainly upon lexical aspect to advance narrative time, at least when their limited vocabulary allowed them to, intermediate learners preferred past perfective verb forms and temporal adverbs. Advanced learners made use of the lexical aspect of eventualities as well as of perfective verbal morphology. However, a breaking in the "principle of natural order", as in the case of simultaneity studied here, could not be expressed at the beginning level and remained a source of difficulty at the intermediate level. Only advanced learners were able to mark this temporal relation, utilizing a variety of means.

What is of particular interest in the described developmental course is the preference for past tense anchoring by intermediate learners. More specifically, beginners frequently shifted between past and non-past verb forms, while the large majority of intermediate learners anchored their narratives in the past with the exception of three speakers. Finally, advanced learners made equal use of past and present tense. The preference of L2 learners for past tense anchoring after the beginning level has been reported in previous studies (Hendriks 1999, Salaberry 2000 and for Greek, Bella 2004-2005). However, this finding is either bypassed (Hendriks 1999) or attributed to the learners perceiving the narration as a classroom task which requires past tense practice (Salaberry 2000). Bella (2004-2005), whose point of interest is indeed the historical present in L2 narratives, suggests that learners who have not been exposed to natural input in the target language do not have the chance to "notice" this function of the present tense and language instruction does not compensate for this fact. To our knowledge, no study has reported the growing preference of advanced learners for present tense anchoring.

We believe that the developmental changes in tense anchoring can be better interpreted if associated with the learners' growing capacities to meet the demands of text production. Oral linguistic communication requires the coordination of different capacities, such as forming grammatical sentences, appropriately linking them, structuring discourse content and adjusting linguistic choices to the communicative situation. At the beginning and intermediate levels, where linguistic performance is

not yet automatised, learners are striving to produce well-structured texts in all of these aspects. However, they cannot attend equally to all these aspects of text production due to cognitive constraints, namely attention limitations (Skehan 1996, Skehan and Foster 1999⁵). It is assumed here that these restrictions direct learners' attention to the construction of sentences or small discourse units, reducing, therefore, attention to the overall hierarchical organization of narrative content as well as to the evaluation of narrated events. As a result, systematic use of the narrative present, as an indicator of a fully developed text macrostructure and an evaluative stylistic shift in narrator's viewpoint, is not expected at lower proficiency levels, but is rather achieved at the advanced level where learners have to some extent automatised language production procedures at a local level.

This explanation may also be pertinent for the relative increased use of adverbs at lower and intermediate levels, even when temporal sequence is marked through other means. These adverbs indicate the learners' need to overmark cohesion at a local level, as a compensation for their inability to attend to the macrostructure of narratives.

It is also worth noting that the methodological approach taken in this study enabled us to detect the growing capacity of learners to construct events with the appropriate to context inherent temporal characteristics. Research on temporal semantics has shown that sentence construction and choice of vocabulary play a crucial role in denoting temporal relations. However, L2 acquisition studies on temporality have mainly focused on whether the type of eventualities determines tense and aspect marking (Bardovi-Harlig 2000, Salaberry and Shirai 2002). In this study we found evidence that constructing the lexical content of sentences has itself a long developmental course in L2 acquisition. Learners' infelicitous choices of vocabulary create vagueness in temporal relations up until the advanced level of proficiency. Thus, it seems that the focused investigation of this parameter of language acquisition is a line of research that can contribute to constructing a more complete picture of how learners express temporal information.

Concluding, adult L2 learners are able to construct the backbone of a narrative even at beginning level, since their cognitive and linguistic/communicative maturity allows them to rely on the inherent temporal properties of eventualities and knowledge about the principles of discourse organisation. However, to unfold all their narrative abilities and to gain control of their text at a global level, they need to develop advanced language skills.

'THERE CAN BE ONLY ONE': THE SINGLE ALLOMORPH SELECTION CONSTRAINT IN GREEK

Athanasios Karasimos
University of Patras, Greece
akarasimos@upatras.gr

ABSTRACT

Interest in the topic of stem allomorphy has been revived in Mark Aronoff's (1994) work. The Central idea of and its later developments (Booij 1997, Pirrelli & Battista 2000a, 2000b, Ralli 2000, 2007, among others) is the notion that the signifiant of a lexeme is not a single phonological representation, but an array of indexed stems. According to Ralli (2000, 2007), stem allomorphy participates in all word formation processes. Additionally, we admit (Karasimos 2008, 2011) that the allomorphic behavior of lexemes hides common patterns. Based on data coming from Greek nominal derivation, the allomorph index of a lexeme is not totally available during word formation. In current research, we suggest that the non-occurrence of all the allomorphs that serve as basis in derived words depends on the constraint of the unique allomorph selection. This constraint is verified by morphological facts and it should be noted that it is applied to all nominal derived words without exception.

Keywords: stem, allomorphy, derivation, compounding, constraints

1. Stem Allomorphy: Introduction

1.1 Stem Allomorphy under the spotlight

Research on stem allomorphy has been revived in Aronoff (1994), whose work has led to novel approaches of inflectional and derivational phenomena in morphological research by Booij (1997), Thornton (1997), Pirrelli & Battista (2000a, 2000b), Ralli (2000, 2007), Stump (2001), Bonami & Boyé (2003), Maiden (2004) among others. Aronoff's main idea also followed by other morphologists is that the signifiant of a lexeme is not a single phonological representation, but an array of indexed stems, which may stand in relations ranging from identity through regular phonological alternation, arbitrary change to full suppletion. (cf. Maiden 2004).

1.2 Definition of Allomorphy and Theoretical Framework

Expanding the definition of Lieber (1982: 27) for allomorphy, what we define as allomoprhs are the different varieties of the same morpheme, which share such lexical information as semantic representation and argument structure, but that differ unpredictably and arbitrarily in their phonological form and in the morphological environments in which they occur (for example κύμα~ κύματ 'wave', παίρν~ πήρ~ παρ 'take'). However, we have to point out that the term is over-used in the literature, since several allomorphs do not qualify for the proper conditions of Lieber's definition.

Ralli (2000, 2007) emphasizes that stem allomorphy is included in the core of morphology and participates in all word formation processes. She suggests that it is one of the basic features for categorizing verbal inflectional classes and nominal inflectional classes.

1.3 The Allomorphic Behavior Principle

Karasimos (2001, 2011) observes that the allomorphic behavior of a morpheme / lexeme is the same in all word formation processes with the unique and systematic exceptions of two specific noun groups that are inflected as the nouns *παιδί* (child) and *τεμπέλης* (lazy_N). These kinds of nominal morphemes participate with new or different allomorphs in derivation and compounding (compared to inflection), since the *παιδί*-type nouns have no allomorphs (e.g. *παιδί* / *παιδι-ά* ‘child / children’ in inflection and the *τεμπέλης*-type nouns participate with a different allomorph than the one(s) used in inflection (e.g. INF *τεμπέλης*: *τεμπελη~ τεμπεληδ* vs. DER/COM *τεμπελ* ‘lazy’).

The morphemes that display allomorphic behavior in word formation processes seem to be depend on their behavior in the process of inflection. The allomorphic behaviour principle determines inflection as the primary field of allomorphic comparison, since most allomorphs ‘were created’ from morphemes reanalysis and from inactive phonological and morphological rules in inflection (see more Karasimos 2011).

(1) i.

κύμα/ κύματ-α	κυματ-ίζω ¹	κυματ-ο-θραύστης
kíma/ kímata	kimat-izo	kimat-o-thrafstis
‘wave’ / ‘waves’	‘to wave’	wavebreaker
καφέ-ς/ καφέδ-ες	καφεδ-άκι	καφεδ-ο-πωλείο
kafé-s/ kafedh-es	kafedh-aki	kafedh-o-polio
‘coffee’ / ‘coffees’	‘small coffee’	‘coffee shop’

ii.

καράβι/ καράβι-α	καραβ-ίσιος	καραβ-ό-σχοινο
karavi/ karavi-a	karav-isios	karavo-o-sxino
‘ship’ / ‘ships’	‘shipborne’	‘headrope’
βάρ-ος/ βάρ-η	βαρ-ίδι	βαρ-ό-μετρο
var-os/ var-i	var-idhi	var-o-metro
‘weight’ / ‘weights’	plumb	barometer
μπακάλη-ς/ μπακάληδ-ες	μπακάλ-ικο	μπακαλ-ό-γατος
bakali-s/ bakalidh-es	bakal-iko	bakal-o-gatos
‘grocer’ / ‘grocers’	‘grocery store’	‘employee in a grocery store’
νταή-ς/ νταήδ-ες	νταηδ-άκος	νταηδ-ό-μαγκας
dai-s/ daidh-es	daidh-akos	daidh-o-magas
‘bully’ / ‘bullies’	‘little bully’	‘bully-and-bloke’

2. Comparing the word formation processes

Comparing the word formation processes of inflection and derivation (and compounding) based on the phenomenon of allomorphy, we can observe several trends among languages. There are languages, like German (2.a), where all the allomorphs of an inflectional paradigm participate in derivation and compounding, while in other languages, such as Dutch and Greek, the above behavior is unlikely to be found.

(2) a. German

Vater ~ Väter	Vaterland	-	Vätersitte
‘father’ – ‘fathers’	‘homeland’		‘ethics of ancestors’
Mutter ~ Mütter	Mutterfreuden	-	Mütterverschickung
‘mother’ – ‘mothers’	‘mother’s joy’		‘mothers’ discharge note’
Buch ~ Bücher	Buchbinder	-	Bücherfolge
‘book’ – ‘books’	‘bookbinder’		‘series of books’

(Lieber 1982)

¹ In these paradigms, I do not separate the inflectional suffixes from the derivational. Also in compounding words, the second component is not separated into their morphemes.

b. Modern Greek

άνθρωπ(ος)	άνθρωπ(οι)	άνθρωπ-ισμ(ός)	ανθρώπ-ιν(ος)
anθrop(os)	anθrop(i)	anθrop-ism(os)	anθrop-in(os)
‘man’	‘men’	‘humanism’	‘human’
αυλή	αυλ(ές)	αυλ-ικ(ός)	αυλ-αία
avli	avl(es)	avl-ik(os)	avl-ea
‘yard’	‘yards’	‘courtier’	‘curtain’
βήμα	βήματ(α)	βηματ-ίζ(ω)	βηματ-άρα
vima	vimat(a)	vimat-iz(o)	vimat-ara
‘step’	‘steps’	‘stride’	‘big step’

However, analyzing data from derivation in Modern Greek, we discover that all the different forms of a morpheme are not fully available during all the word formation processes. For example the noun *βήμα* ‘wave’ displays two allomorphs *βήμα*~ *βήματ* in inflection, it displays only one morpheme form in the process of derivation (*βήματ*~), e.g. *βηματάκι* ‘small step’, *βηματάρα* ‘big step’, *βηματίζω* ‘stride’. The same allomorphic pattern of this noun is observed in the process of compounding, in examples such as *βηματοδότης* ‘pacemaker’, *βηματομέτρηση* ‘step counting’. As it is demonstrated in the following session (3.), such allomorphic behavior is not random and is solely due to a constraint that applies to all nominal and adjectival stems and suffixes.

3. The Single Allomorph Selection Constraint

The process of derivation contains principles and constraints about the categories of stems of derived words that are combined with derivational suffixes. The most common constraint for input-type cases (input constraint) is the number of requirements of a base-stem to be chosen and combined by derivational suffixes. There are a few derivational processes that require even more limited bases. Let's take some examples from German (Riehemann 1998: 54) and Modern Greek:

(3) a. German

essen ‘eat’	essbar ‘eatable’
zahlen ‘pay’	zahlbar ‘payable’
halten ‘hold’	haltbar ‘durable’

b. Modern Greek

ταξί ‘taxi’	ταξιτζής ‘taxi driver’
καφές ‘coffee’	καφετζής ‘coffee shop owner’
τζάμι ‘glass’	τζαμτζής ‘glazier’
σαπούνι ‘soap’	σαπουντζής ‘soapmaker’

Analyzing the above examples from German, the derivational suffix *-bar* is combined only with base-stems that are transitive verbs to form adjectives; a similar case is the corresponding suffix *-baar* from Dutch (Booij 2006: 62), which requires the same context subcategorization. For example, the word *drink-baar* ‘drinkable’ is derived from the transitive verb *drink* ‘drink’. In Modern Greek there are few derivational suffixes which are attached to specific stems, such as the suffix *-τζή(ς)* in (3.b) which combines only with nominal bases and stems. On the other hand there are several suffixes that do not present any combinational constraints with bases, since they can attach to nominal, adjectival and verbal stems (even adverbial bases). In English the suffix *-er* is combined with verbs (*keep* >> *keeper*, *print* >> *printer*) and nouns (*Berlin* >> *Berliner*). The greek verbal derivational suffix *-ε(ω)* combines with nominal stems (*χορ-ός* ‘dance’ >> *χορεύω* ‘dance’) with adjectival stems (*ήμερ-ος* ‘meek’ >> *ημερεύω* ‘tame’) and with adverbial stems (*κοντά* ‘close’ >> *κοντεύω* ‘getting close’).

More specifically, we maintain that the non-appearance of all the allomorphs as bases in derivation is not random, occasional or not independent from the morphological environment in which the allomorphs appear. I have previously suggested (Καρασίμος 2011a, 2011b) that nominal bases of derived words and nominal stems as first constituents of compound words allow the appearance of only

one allomorph due to a constraint that takes place in the input configuration of a derived or compound word; this constraint prevents the appearance of all allomorphs of each morpheme as basis on a nominal derived word. We call this specific limitation of selection **single-allomorph selection constraint**. I have observed that the Greek derived words fall under the restrictions of this constraint and some allomorphs that participate in inflection are excluded. Since the constraints do not usually apply randomly in a language, but for a reason, I point out that the single-allomorph selection constraint ensures unique uniformity among derived words with a common basis through the appearance of only one form of the morpheme-base.

In the present article, I suggest that the non-appearance of all allomorphs as bases in derivation does not depend on the process itself, since the phenomenon appears also in compounding. I believe that in Modern Greek the reasons for the occurrence of single-allomorph selection constraint are independent; the selection of the single-allomorph is neither random and arbitrary, nor unpredictable. In fact, this particular constraint applies mainly for morphological and phonological reasons.

3.1 Optional phonological conditions

Checking carefully the phonological structure of a derived word base, the existence of stems with a final-character consonant is statistically more significant than with a final-character vowel. According to Ralli's inflectional model (2000)², the nouns in Modern Greek that display allomorphs, have an allomorph that ends with a vowel and another one that ends with a consonant (4.b). The inflectional classes with no allomorphs at all have in majority stems with ending of the XC-type³ (4.a). The only and systematic exception is the sixth inflectional class of *καράβι*-type neutral nouns (4.c, see Karasimos 2011a). On the other hand, verbs with systematic allomorphy (5.a, second inflectional class according to Ralli's model (2004)) display a stem with a final-character consonant and a stem with a final-character vowel (X ~ XV); other verbs without systematic allomorphy (5.b, first inflectional class, see above) can have all their allomorphic types with a consonant as a thematic character.

(4) a.	άνθρωπ-ος		
	anθrop-os		‘man’
	δάσ-ος		
	das-os		‘forest’
	μωρ-ό		
	mor-o		‘baby’
b.	πάπα-ς	παπάδ-ες	
	papa-s	papaδ-es	‘priest’ – ‘priests’
	θάλασσα	θάλασσ-ες	
	thalasa	thalasa	‘sea’ – ‘seas’
	κύμα	κύματ-α	
	kima	kimat-a	‘wave’ – ‘waves’
c.	καράβι	καράβι-α	
	karavi	karavi-a	‘ship’ – ‘ships’
	τραπέζι	τραπέζι-α	
	trapezi	trapezi-a	‘table’ – ‘tables’
	μολύβι	μολύβι-α	
	molivi	molivi-a	‘pencil’ – ‘pencils’
(5) a.	αγαπ-ώ	αγάπη-σα	
	agap-o	agapi-sa	‘love’ – ‘loved’
	πηδ-ώ	πήδη-σα	
	pidi-o	pidi-sa	‘jump’ – ‘jumped’

² Ralli (2000) suggests that there are eight inflectional nominal classes in Modern Greek. The first two contain masculine nouns, the third and fourth (include) feminine nouns and the rest neutral nouns.

³ XC-type: any kind of phoneme (X) and a consonant (C).

	αφαιρ-ώ afer-o	αφαίρε-σα afere-sa	‘remove’ – ‘removed’
b.	πλέν-ω plen-o	έ-πλυν-α e-plin-a	‘wash’ – ‘washed’
	ξεχν-ώ ksexn-o	ξεχα-σα ksexa-sa	‘forget’ – ‘forgot’
	ρουφ-ώ ruf-o	ρουφηγ-σα ⁴ rufiy-sa	‘suck’ – ‘sucked’

Structurally, over eighty percent of the derivational suffixes that combine with nouns/ or nominal bases and adjectives/ or adjectival bases start/begin with a vowel. To maintain the optimal syllabic structure CV, the base “should” have a morpheme ending with a consonant (if applicable). Therefore, although it does not form a requirement, the allomorph ending with a consonant is qualified as the only and final choice. For example, the verbal suffix *-ιζ(ω)*, when combined with the lexeme KYMA ‘wave’ which has the allomorphs *κυμα~ κυματ*; the allomorph *κυματ* is joined with the derivational suffix and that way the optimal syllabic structure is achieved. The highly productive subclass of diminutive and augmentative derivational suffixes have all their suffixes starting with vowel, like *-άκι*, *-άρα*, *-ούτσικος*, *-ούκλα-*, *-ούλα*, *-ίτσα* etc, among others.

I have to clarify here that I do not maintain that the derivational suffix selects the proper allomorph of the base/ stem/ root, but that the phonological structure of the suffix justifies the “choice” of the specific stem allomorph. Moreover, there are a few derived words with their optimal syllabic structure violated in the absence of an alternative morpheme (allomorph), as for example the stem *λα(ός)* ‘people’ > *λα-ικ(ος)* ‘folkish’, *μυστήρι(ο)* ‘mystery’ > *μυστηρι-ακ(ος)* ‘mystic’, *ράβ(ω)* ‘sew’ > *ράφ-τη(ς)* ‘tailor’. Therefore, the derivational suffix does not require a specific form of a basis-morpheme, since if that was the case, then this characteristic would constitute a universal property of all suffixes, which is to select the proper form of a basis-morpheme.

3.2 Morphological conditions

All the derived words in Modern Greek have two components, a morpheme –base or a derived stem (non-head position) and a derivational suffix (head position) that applies to the basis. In the non-head position, the morphemes with two or three allomorphs cannot display all the possible forms. Therefore, every allomorph is marked with the context information and the morphological environment to avoid the possibilities of ungrammatical derived words (e.g. **ψυχη-ισμ(ός)* instead of *ψυχ-ισμ(ός)* ‘psychism’, **παίρσιμο/ *πήρσιμο* instead of *πάρσιμο* ‘taking’, **βαθύως* instead of *βαθέως* ‘deeply’. **κονταεύω* instead of **κοντεύω* ‘approach’).

The derivational suffixes “adopt” the same allomorphic behavior as the stems. Therefore, we expect that the suffixes share the same context information and morphological environment with their allomorphs. More specifically, when a derivational suffix, that is going to be combined with a simple or a derived stem, is followed by another derivational suffix, it will be placed in the second level of derivation process in a non-head position and will display only one allomorph. Derived base is called the combination of a stem and a derivational suffix, e.g. [*ανθρώπ-ιν-*] ‘human.NoINF⁵’, [*χορ-εϋ-*] ‘dance_v.NoINF’, [*ομορφ-ότερ-*] ‘more beautiful.NoINF’.

Plag (1999) and Hay & Plag (2004) claim that the basis of a derived word demands a specific allomorph of the derivational suffix; we maintain that this fact can be modified in Modern Greek derivation. More specifically, the basis demands a specific allomorph of derivational suffix *if and only if* the derivational suffix participates in another derivational suffixation process; thus it is obliged to obey the single-allomorph selection constraint. In English, such constraints apply only to specific groups of morphemes or suffixes. On the contrary, in Modern Greek each base selects the proper allomorph of a suffix, if it is any further suffixation (6.a). A similar procedure applies in cases of suffixation in compound words, such as *χορ-ο-πηδηχ-τ-ούλης* ‘gamboler’, *δικτυ-ο-τρομο-κρα-τ-ικ-ός* ‘cyber-terroristic’, *αερ-ο-μαχη-τ-ικ-ο* ‘air-fighter plane’ (6.b).

⁴ The type ‘ρούφηξα’ is created after the phonological rule of dissimilation.

⁵ NoINF = absence of inflectional suffix.

(6) a.	κλαίω kleo 'cry'	κλαι~ κλα kle~ kla 'allomorphs of cry'	DER	κλά-μα/ κλά-ματ-α kla-ma/ kla-mat-a 'crying / cryings'	>>	κλα-ματ-άκι kla-mat-aki 'short crying'
b.	αέρας (αερα~ αερ) + μάχομαι aeras (aera~ aer) + maxome 'air' 'fight'	COM	αερ-ο-μαχη-τη-ς aer-o-maxi-ti-s 'pilot-fighter'			αερ-ο-μαχη-τ-ικ-ο aer-o-maxi-t-ik-o 'air-fighter plane'

No information for the morphological environment of a non-head position is included in languages like German. The allomorphs of/in German are characterized by Lieber (1980) as singular and plural ones; she uses inflectional terms to categorize allomorphy. This characterization is not only morphological concerning the inflectional paradigm, but it is also semantic, because it implies the meaning of the singularity (SINGULAR) and quantity (PLURAL), as it is mentioned by Lieber (2.a). On the contrary, in Modern Greek it is possible for two allomorphs to occur in the same inflectional sub-paradigm, as for e.g. the nouns of IC8 (*βήμα*-type nouns) that 'use' the "plural" allomorph-t (*βήματ-α* 'steps', *κύματ-α* 'waves', *μαθήματ-α* 'lessons') also in the singular genitive (*βήματ-ος* 'of step', *κύματ-ος* 'of wave', *μαθήματ-ος* 'of lesson'). Furthermore, the allomorphs in Modern Greek are characterized by morphological information and do not contain any potentially hidden non-morphological information, such as semantic markedness. Additional morpho-semantic information for a lexeme, such as if it/ that is an Ancient Greek relic, puristic Greek, or a calque, is not attached to its allomorphs, since this information is not helpful for the selection of the proper allomorph in derivation and compounding. According to Booij (1997), the feature [+ CALQUE] in Dutch seems to cause a different behavior in lexemes and the selection of a non-expected allomorph.

3.3 'Counterexamples' of single-allomorph selection constraint

Drachman (2006) gives some examples from Modern Greek, which seem to form exceptions of the single-allomorph selection constraint. He introduces the term 'shared allomorphs' which 'are produced' from a basic form, have an independent status in the word formation processes involved, but are more or less related to each other, so in essence the notion of 'derived from' or 'created from' is no longer necessary.

(7) a.	κρέ-ας/ κρέατ-α kreat-as/ kreat-a 'meat'/'meats'	κρεατ-ερό, κρεατ-ίλα, κρεατ-ινό kreat-ero, kreat-ila, kreat-ino 'fleshy' 'smell-of-the-meat' 'of-meat'
		κρε-ο-πώλης, κρε-ο-φάγος, κρε-ο-κοφ-τήρας kreat-o-polis, kreat-o-fagos, kreat-o-kof-tiras 'butcher' 'meat-eater' 'mincing machine'
		κρεατ-ο-πωλείο, κρεατ-ο-σανίδα, κρεατ-ο-πιτα kreat-o-polio, kreat-o-sanida, kreat-o-pita 'butcher's shop' 'meat-board' 'mince pie'
	αίμ-α/ αίματ-α em-a/ emata 'blood'/'bloods'	αιματ-άκι, αιμάτ-ωμα emat-aki, emat-oma 'hematoma'
		αιμ-ο-σφαίρια, αιμ-ο-δοσία, αιμ-ο-ρραγία em-o-sferia, em-o-dosia, em-o-rajia 'blood capsule' 'blood donation' 'bleeding'
		αιματ-ο-βαμμένος, αιματ-ο-κύλισμα, γλυκ-ο-αίματ-ος emat-o-vamenos, emat-o-kilisma, glyk-o-emat-os 'bloodstained' 'carnage' 'sweet-blood'
b.	(η)μέρα (i)mera	ημερίσιος (*μερίσιος), ημερομίσθιο (*μερομίσθιο) imerisios (*merisios), imeromisθio (*meromisθio) 'daily' 'wage'
		μερόνυχτα

	meronixta	
	‘days and nights’	
(ε)νοίκι(ο)	νοικιάζω, ενοικιαστής (*νοικιαστής), νοικιάρης (*ενοικιάρης)	
(ε)νιcι(ο)	nicjazo, enicjastis (*nicjastis), nicjaris (*enicjaris)	
	‘rentv’ ‘tenant’	‘roomer’
(ο)μιλώ	μίλησε, ομιλητής (*μιλητής)	
(ο)milo	milise, omilitis (*militis)	
	‘spoke’ ‘speaker’	

(Drachman 2006: 14, 19)

The examples in (7a) seems that they seem to be counterexamples of the constraint presented here; however, the truth lies somewhere in the middle. First of all, I have to underline that this constraint has no exceptions of derived words with nominal and adjectival stems. The case of the noun αίμα ‘blood’ with the allomorphs αιμα~ αιματ~ αιμ, Karasimos (2001) has exhibited its peculiar behavior in the process of compounding. The derived words from αίμα ‘blood’ use only the allomorph αιματ~, obeying to the single-allomorph selection constraint. The compound words from αιμα are divided into three groups: (a) compound words with the stem αιματ~ as their second component, (b) compound words with the allomorph αιμ~ as their first component; these words came from French, Ancient Greek or International Greek and (c) compound words with the allomorph αιματ~ as their first component; these words came from English or from Modern Greek. As Ralli & Karasimos (2008, 2009a, 2009b) argue for the bare-stem constraint, the compound words formed in International Greek or by non-native speakers, violate the rules, principles and constraints of the compounding process, as they are created outside of the morphological word formation processes of the Greek language. Regarding the case of the noun κρέας ‘meat’ with the allomorphs κρεα~ κρεατ~ κρε~, its derived words follow the constraint without exceptions, while the word participates in compounding with two allomorphs (κρεατ~ κρε), since it is a word from Ancient Greek with a double inflectional paradigm (see Economou 1971: 85-86); therefore the ‘relic-type allomorph’ κρε~ is used into words that were created in previous phases of Greek. Furthermore, the examples (7b) are in no way allomorphs, as the optional phonological deletion of the initial vowel, by definition, does not constitute a case of allomorphy (see Karasimos 2011a).

Finally, it is necessary to point out that the single-allomorph constraint makes no exception in the whole process of derivation and applies to all nominal and adjectival stems (we except that there will not are also no exceptions in Modern Greek Dialects) and allows us to predict which allomorph is going to be used. In languages, like German (Lieber 1981) the single-allomorph selection constraint does not exist, but we expect that languages with extended allomorphy may display this constraint.

4. Conclusion

The derivational suffix does not force the base of a derived word to participate with the proper allomorph, as this would be a universal feature of all suffixes. The single-allomorph selection constraint applies in Modern Greek, is definitely not a universal constraint, but it may also apply in other allomorphically rich languages. This constraint refers to a morphological phenomenon (allomorphy) which changes are arbitrary and unpredictable; however the constraint is characterized by predictability and regularity. Furthermore, Karasimos (2011a) claims that this constraint provides us important advantages to analyze computationally this phenomenon, to export allomorphic rules and to improve the performance of a parser through predictability of allomorph selection.

ABSTRACT

This paper describes ongoing work for annotation of events in Greek corpora following the specifications of the TimeML standard adapted to the Greek language. We first briefly outline the task of event recognition and the history of related annotation efforts. After that we discuss the tags used in the annotation process for a Greek Event Annotated Corpus and we provide indicative examples from the guidelines.

1. Introduction

Detection and analysis of events and their various realizations in natural language has been examined by philosophers, psychologists and linguists (Vendler, 1967). In computational linguistics and artificial intelligence, event detection is of great interest for developing complex natural language processing applications like narrative understanding, information extraction, automatic summarization and question answering. Large collections of text available today need to be robustly analyzed in order to be searchable from machines and event recognizers are crucial components of textual analytics systems that try to extract information necessary in creating automatic summaries and/or in answering questions like: “Ποιες ήταν οι σπουδαιότερες μάχες που έγιναν τον τελευταίο χρόνο του Β’ Παγκοσμίου Πολέμου; Ποιες τράπεζες κατέρρευσαν το 2011;”

Many different approaches to event detection have been presented in the relevant literature. The ultimate goal of these approaches is the development of applications that automatically extract facts and recognize spatiotemporal relations between them (Παπαγεωργίου κ.α., 2007). Events are usually studied in terms of either their semantic structure or of their spatio-temporal dimension in relevant annotated corpora needed for developing and testing event recognizers. In this paper, we present our effort for the creation of a Greek Event Annotated Corpus (GEAC) based on the model of the Time Markup Language (TimeML, <http://timeml.org>).

2. Annotation schemas for time and events

One of the first efforts for annotation of events, temporal expressions and relations between them is Setzer and Gaizauskas (2001), who developed the Sheffield Temporal Annotation Guidelines. STAG was a scheme that categorized events to be marked up in occurrence, perception, reporting, and aspectual classes. The scheme also included the *relatedToEvent* and *relatedToTime* attributes, which corresponded to references to other events or temporal expressions. A *relType* attribute was used for expressing the nature of the reference and had the following values: BEFORE, AFTER, INCLUDES, IS_INCLUDED and SIMULTANEOUS. The last one was a “cover value” for all types of temporal overlaps. An annotation example according to STAG is the following:

The boy arrived on Thursday.
The boy <event eid="9" class="OCCURRENCE" tense="PAST" relatedToTime="5" relType="IS_INCLUDED">arrived</event> on <timex tid="5">Thursday</timex>.

The Automatic Content Extraction 2005 Evaluation included a detection task for events with specific semantics (Table 1) that had entities and temporal expressions as arguments. ACE events were also annotated for modality, polarity, tense and genericity.

Event type	Subtypes
Life	be -born, marry, divorce, injure, die
Movement	Transport
Transaction	Transfer-ownership, transfer-money
Business	start-org, merge-org, declare-bankruptcy, end-org
Conflict	attack, demonstrate
Personnel	start-position, end-position, nominate, elect
Justice	arrest-jail, release-parole, trial-hearing
Contact	meet, phone-write

Table 1 Event types and example subtypes from the ACE 2005 Evaluation

The designers of the TimeML (Pustejovsky et al., 2003a) integrated and expanded elements from previous efforts and STAG in particular. The main TimeML tags include TIMEX3, EVENT, MAKEINSTANCE and three types of links. The reference corpus for TimeML is TimeBank (Pustejovsky et al., 2003b), a resource that contains 183 news articles with 61K non-punctuation tokens and is available from <http://www.timeml.org>. The latest version (1.2) of TimeBank includes 8K events, 1.4K TIMEX3 tags and 9.6K links. Similar resources for other languages include timebanks for Spanish, Italian, Chinese, Korean and French that range from 10K to 60K tokens. Some of them have been used in shared tasks for the evaluation of automatic multilingual event annotation (Verhagen et al., 2010).

3. A Greek Event Annotated Corpus

The main properties for each TimeML element are described in the following subsections, with particular focus on the EVENT and the MAKEINSTANCE tag. Each description is accompanied by Greek examples that we have collected in order to develop guidelines for the GEAC. In its current version, GEAC contains 41 annotated texts, including news articles, historical narratives and travel documentaries. We drew these documents from online newspaper sites, the Greek Wikipedia and transcripts of TV interviews on historical periods. The total size of the corpus amounts to 31,920 words and it is currently annotated for temporal expressions and events only. The annotation editor we used was Callisto (

Figure 1), a freely available tool from the non-profit organization MITRE. An alternative environment for event and other annotation tasks is the Brandeis Annotation Tool (Verhagen, 2010).

Figure 1 Annotating MAKEINSTANCE tags (Section 3.3) with Callisto, the editor used for the construction of the Greek Event Annotated corpus

3.1. The TIMEX3 tag

Temporal expression annotation is accomplished through the TIMEX3 tag. TIMEX3 markables include dates, times, and durations. The temporal value of these markables appears explicitly in the text or can be defined in relation to another explicit expression, including the document creation time. The next example shows the annotation of an explicit TIMEX3:

Έφυγα από την Γερμανία στις 2 Αυγούστου του 2009.

```
<TIMEX3 tid= 't1' type= 'DATE' value = '2009-08-02' temporalFunction = 'FALSE'>02 Αυγούστου του 2009</TIMEX3>
```

Each TIMEX3 includes a unique identification attribute (tid) which can be used in other tags for reference to this expression. The value attribute is used for normalizing durations (δώδεκα βδομάδες: P12W), times (8:05 της 21ης Φεβρουαρίου 2009: 2009-02-21T08:05:00). The *temporalFunction* attribute has a value FALSE since the expression can be unambiguously evaluated in the text. Other expressions like *χθες* have to be anchored to another expression for their value to be defined. Thus, given the 't1' expression above, the following example should be annotated as follows:

Την επόμενη μέρα έφτασα στην Πάτρα.

```
<TIMEX3 tid= 't2' type= 'DATE' value= '2009-08-03' temporalFunction= 'TRUE' anchorTimeID = 't1' > επόμενη μέρα </TIMEX3>
```

3.2. The EVENT tag

According to TimeML, events are "situations that happen or occur". The term also includes situations that change throughout the text or states that hold true. State events are considered markables if they develop or change in the text, if they are directly related to a specific TIMEX3, or if they are introduced by another event. Expressions that are not annotated include generics not referring to temporally anchored events (*οι κρατούμενοι απαγορεύεται να κρατάνε όπλα, τα αντικείμενα πέφτουν λόγω της βαρύτητας*), verbs introducing generics (*είπε ότι η Γη γυρίζει γύρω από τη Σελήνη*), nominalizations that provide no further information beyond that of their associated verb (*δημοσιεύματα σε εφημερίδες αναφέρουν...*). Events can be punctual or last for a period of time, and they can be realized as verbs (*ο διαιτητής διέκοψε τον αγώνα*), nouns (*η βροχόπτωση προκάλεσε ζημιές*), adjectives (*τα κέρδη ήταν ελαφρά υψηλότερα*), prepositional phrases (*ένας υπάλληλος σε διαθεσιμότητα κατηγορείται ...*) and participles (*η κατεστραμμένη από τη χαλαζόπτωση σοδειά θα αποζημιωθεί*).

Our guidelines contain instructions for typical constructions. If an event is realized as a verbal cluster containing an aspectual and a main verb, both verbs are annotated as individual events. The set of aspectual verbs includes the verbs *αρχίζω, σταματώ, τελειώνω, συνεχίζω, etc.* In the case of events realized as noun phrases, only the head is annotated and any modifiers are excluded from annotation (*παρατήρησαν σημαντική βελτίωση*). In the case of events in prepositional phrases, we annotate the head of the embedded NP (*βρίσκεται από χθες σε διαθεσιμότητα*). For events realized as predicative complements of copula verbs, we annotate only the complement (*ήταν δάσκαλος*). If an event is realized as a nominalization preceded by a support verb (*δημιουργούν εντυπώσεις*), both words are annotated as individual events, which are linked via an IDENTICAL TLINK (see Section 3.4). In the case of causative predicates (*η επίθεση προκάλεσε την οργή των αιγυπτιακών αρχών*), it is often difficult to distinguish the event introduced by the causative predicate from the result event. For constructions with similar predicates (*προκαλώ, οδηγώ σε, προξενώ, επιφέρω*), we annotate three events if the subject is an event itself, and we create a BEFORE TLINK between the subject and the object event.

Each event has to be classified on the basis of its semantic and factual characteristics. The set of classes includes REPORTING, PERCEPTION, ASPECTUAL, I_ACTION, I_STATE, STATE, and OCCURRENCE events. Reporting events (*λέω, εξηγώ, δηλώνω, περιγράφω, διευκρινίζω, ξεκαθαρίζω, διατυπώνω, ανακοινώνω, σχολιάζω*) describe the action of an entity declaring something or providing information about an event, etc:

Ιστορικές πηγές αναφέρουν ότι ο πόλεμος του '40 επηρέαζει και τις σύγχρονες γενιές.
Σχολιάζοντας τα αποτελέσματα εννεαμήνου...
Δήλωσε ο Υπουργός Πολιτισμού.
Παράλληλα η ΕΣΥΕ ανακοίνωσε ότι ο δείκτης όγκου λιανικών πωλήσεων.
Αναφερόμενος στο θέμα, ο «ισχυρός άνδρας» της Ράπιντ μίλησε στην εφημερίδα της Ρουμανίας.
Η Εθνική Τράπεζα είπε ότι τα καθαρά κέρδη αυξήθηκαν 48%.

Perception events (*βλέπω, ακούω, κοιτάω, διακρίνω, παρακολουθώ, παρατηρώ, ατενίζω, θωρώ, ακούω, παρακούω*) are used to describe the physical perception of another event:

Από την άλλη παρατηρήσαμε και πάλι στενότητα στις συνθήκες ρευστότητας.
Το είδατε στην Τουρκία.
Πρώτα να δούμε σε τι κατάσταση θα είναι οι παίκτες.
Η χαρά μου ήταν μεγάλη που άκουσα τη φωνή τους.
Έβλεπα με τα μάτια μου τα άλογα που πέθαιναν από τα χτυπήματα.

Aspectual events focus on different temporal facets of an event introduced by the aspectual event. This class includes initiation (*αρχίζω, ξεκινώ*), reinitiation (*ξαναξεκινώ*), termination (*σταματώ, τερματίζω, διακόπτω, αναβάλλω, ανακαλώ, ματαιώνω*), culmination (*τελειώνω, ολοκληρώνω*) and continuation (*συνεχίζω, εξακολουθώ, επιμένω*) events:

Με υψηλό ρυθμό συνεχίζει να τρέχει η ελληνική οικονομία.
Μετά από δυο μέρες άρχισαν οι ανακρίσεις.

Intensional action events (I-ACTION) include verbs that introduce an argument which must exist in the text and which describes an event or a state, for which we can infer something, given its relation to the I-ACTION verb. For example, the eventual arguments of the first group of sentences below did not necessarily occur.

προσπαθώ, επιχειρώ, αποπειρώμαι, δοκιμάζω
Με την κίνηση αυτή προσπαθεί να αιφνιδιάσει.
Και οπωσδήποτε προσπάθησε να κρατήσει κάποια απόσταση.

ερευνώ, ψάχνω, διερευνώ, εξετάζω
Έψαχναν να μας βρουν για 13 χρόνια
Θα ερευνήσουν την οργανωμένη γενοκτονία χιλιάδων Εβραίων.

καθυστερώ, αναβάλλω, αργοπορώ, επιβραδύνω, χρονοτριβώ, εμποδίζω, αναστέλλω
Τότε όμως καθυστερούσαν να φτάσουν γιατί στη διαδρομή βρίσκονταν οι ενδιαμέσες φυλακές.
Κι έτσι ανέβαλε το ταξίδι.

αποφεύγω, προλαμβάνω, εμποδίζω

Προσπαθούσαν να εμποδίσουν τους στρατιώτες τους από να έχουν σχέσεις με τους ντόπιους.
Ο Υπουργός απέφυγε να απαντήσει στις ερωτήσεις.

ρωτώ, ζητώ, παρακαλώ, προστάζω, διατάζω, παραγγέλλω, πείθω, αιτούμαι, ικετεύω, παροτρύνω, προτρέπω, παρακινώ

Θέλω να σας ζητήσω και γραπτώς να με συγχωρήσετε
Προσφέρθηκε να επισκευάσει το ποδήλατό της

υπόσχομαι, τάζω, προσφέρω, προσφέρομαι, διαβεβαιώνω, βεβαιώνω, προτείνω, προτίθεμαι, συμφωνώ, δέχομαι, αποφασίζω, καθορίζω, επιτρέπω

Η ΟΥΕΦΑ τους επέτρεψε να χρησιμοποιήσει τον αδήλωτο Μπέτε
Μου υποσχέθηκε να γυρίσει νωρίς το βράδυ.

ισχυρίζομαι, προτείνω, υπαινίσσομαι, εισηγούμαι, υποδηλώνω, υποστηρίζω

Ισχυρίστηκαν ότι δεν είχαν μαζί τους τίποτα άλλο αξιόλογο
Πρότεινε στη μαμά μου να πλένει τα πουκάμισα των Γερμανών

The intensional state (I-STATE) class is used for states that refer to alternative or possible worlds where their argument might occur:

πιστεύω, νομίζω, φρονώ, σκέπτομαι, κρίνω, υποψιάζομαι, υποπτεύομαι, αισθάνομαι, νιώθω

Το πιστεύατε ότι θα τις βρείτε ποτέ;
Νόμιζαν πως είχε αποπλεύσει από τη Ρόδο.

θέλω, χρειάζομαι, αρέσει να..., βρίσκω καλό, επιθυμώ, λαχταρώ, ποθώ

Θέλουν να φύγουν από την Αϊτή.
Υπάρχουν οικογένειες που θα ήθελαν να υιοθετήσουν ένα παιδί από την Ασία

ελπίζω, περιμένω, ευελπιστώ, προσδοκώ, αναμένω, φιλοδοξώ, σχεδιάζω

Ο Παπαδόπουλος φιλοδοξεί να πάρει μεταγραφή στην Αγγλία

Οι αρχές φοβούνται ότι δε θα είναι σε θέση να αντιμετωπίσουν...
Οι συγγενείς του ανησυχούν για την έκβαση της υγείας του

είμαι σε θέση, μπορώ

Το σχολείο δε θα είναι σε θέση να δεχτεί περισσότερους μαθητές την επόμενη χρονιά.

STATE events describe circumstances in which something holds true. We annotate a) states that change in the temporal framework of the text being annotated, b) states that are directly related to a temporal expression c) states that are introduced by an I-ACTION or a REPORTING event and d) states realized by a copula verb and a predicative complement if the state depends on the document creation time. In the example below, the relation of the airplane to the owner company does not change during the temporal framework of the text. Thus it is not annotated as a STATE. On the contrary, the state expressed by *επέβαιναν* changes during the document framework and is to be annotated.

Και οι 125 άνθρωποι που επέβαιναν στο airbus της Quantas σώθηκαν.

In a similar way, the complements of verbs like *είμαι* and *βρίσκομαι* are to be annotated as states since they can be interpreted only in a relation to the document creation time.

Ισχυρές ναυτικές δυνάμεις αποτελούμενες από 15 πολεμικά πλοία βρίσκονται στο λιμάνι του Πειραιά.

The next two examples regard states that are related to a temporal expression and should be connected to these expressions via a TLINK.

Ο Κωνσταντίνος Καραμανλής διετέλεσε Πρωθυπουργός της Ελλάδας για 5 χρόνια.

Έμειναν σε καταυλισμό για αρκετά χρόνια.

Occurrence events are all the other kinds of events describing something that happens or occurs in the world.

Η ΑΕΚ *νίκησε* με 3-0 την Ρόμα.

The classes of the events described above are not uniformly represented in GEAC. Not surprisingly, the occurrence class is the most frequent one, followed by events classified as states (Table 2).

Event class	Percentage
Occurrence	65,15%
State	21,63%
Reporting	3,71%
I-action	3,12%
Aspectual	3,02%
I-state	2,27%
Perception	1,08%

Table 2 Event classes and their distribution in the Greek Event Annotated Corpus

3.3. The MAKEINSTANCE tag

Events in TimeML are distinguished from their realizations. Thus, each EVENT tag is accompanied by at least one MAKEINSTANCE, a tag that is used for the specification of the actual realization of an event. It includes information like the id of the event it refers to, together with attributes concerning tense, aspect, non-finite morphology, polarity, modality, and cardinality.

In most cases, only one MAKEINSTANCE is needed and it is automatically created and associated with a new EVENT tag by the annotation editor. Thus, the human annotator has only to create additional MAKEINSTANCE tags for the second (and more, if needed) instances when an event is associated with two or more temporal expressions:

Η Μαρία δίδαξε τη Δευτέρα και την Τρίτη.
 <MAKEINSTANCE eiid="ei1" eventID="e1" tense="PAST" aspect="NONE"
 pos="VERB"/>
 <MAKEINSTANCE eiid="ei2" eventID="e1" tense="PAST" aspect="NONE"
 pos="VERB"/>

There are also cases, when the human annotator can either create as many MAKEINSTANCE tags as needed or, for large numbers of instances, just one MAKEINSTANCE that includes cardinality information:

Η Μαρία δίδαξε δύο φορές τη Δευτέρα
 Η Μαρία δίδαξε 150 φορές πέρυσι

Tense and aspect attributes of MAKEINSTANCE tags are non-optional. Possible values for tense are PAST, PRESENT, FUTURE, or NONE. Aspect can be assigned values from PROGRESSIVE, PERFECTIVE, PROGRESSIVE_PERFECTIVE, or NONE.

Figure 2 presents some typical annotations for finite verbal types.

Example	Tense	Aspect
Δεν βλέπει να ανεβαίνουν στην κατηγορία	PRESENT	NONE
έχει αναθέσει τη διαχείριση σε τρίτους	PRESENT	PERFECTIVE
Τα στρατεύματα μαζεύονταν γύρω από το νησί	PAST	PROGRESSIVE
Ο ΑΓΕΕΘΑ πρότεινε αύξηση της θητείας	PAST	NONE
Είχαν φύγει πριν να γυρίσω	PAST	PERFECTIVE
Όλοι θα θέλουν δεύτερο και τρίτο	FUTURE	PROGRESSIVE
Εμείς θα κερδίσουμε με τη Ντινάμο	FUTURE	NONE
Θα έχει σχολάσει απ' τη δουλειά του στις 6	FUTURE	PERFECTIVE

Figure 2 Annotation of tense and aspect attributes for finite verbal types

The non-finite morphology attribute is mainly used for non-verbal events and can take the following values: ADJECTIVE, NOUN, PRESPART, PASTPART, or NONE. All finite verbal types are assigned a NONE value, while PRESPART and PASTPART values are reserved for participles like *ερευνώντας* and *διορισμένος*. The polarity attribute depends on whether the event instance is negated or not in the text (*δεν έπλυνε*) and it can either be assigned the implied default value POS, or NEG.

3.4. The LINK tags

When all events and temporal expressions have been annotated in a text, the next step is to define relations between these events (actually MAKEINSTANCES) and temporal expressions using temporal links (TLINK), aspectual links (ALINK) and subordination links (SLINK). Although we have not yet annotated LINKs in GEAC, we provide in this subsection a brief overview of these TimeML tags, together with indicative examples from our guidelines for Greek.

The large majority of the 9615 links in TimeBank 1.2 are TLINKs (6418) followed by 2932 SLINKs, and 265 ALINKs. TLINKs depict the temporal relation between two events, two temporal expressions or between an event and a temporal expression. A *relType* attribute describes explicitly the nature of this relation.

Table 3 presents some of the possible values for the *relType* attribute.

relType	Example	relType	Example
Before	Έφυγε πριν να γυρίσω	Simultaneous	Όσο η Αντιγόνη έπαιζε, η Αρετή διάβαζε
After	Τον συνάντησα μετά τη γέννηση της Βιολέτας	Immediately After	Όλοι οι επιβάτες πέθαναν μόλις ανατινάχθηκε το αεροπλάνο.
Includes	Έφυγε για το χωριό την προηγούμενη Τετάρτη	Begins	Η δικτατορία διήρκεσε από το 1967 μέχρι το 1974
During	Δίδασκε σ' αυτό το σχολείο για 30 χρόνια	Ends	Η δικτατορία διήρκεσε από το 1967 μέχρι το 1974

Table 3 TLINK relation types and examples

ALINKs connect an aspectual event with another event. Table 4 presents possible values for the *relType* attribute of ALINKs, together with indicative examples.

relType	Example
initiates	άρχισε να πουλάει την περιουσία του
culminates	ολοκλήρωσε τη συμφωνία με τους Άραβες
terminates	η Σπίθα σταμάτησε να γαβγίζει
continues	συνέχισε να την ενοχλεί
reinitiates	ξανάρχισαν να παίζουν

Table 4 ALINK relation types and examples

Finally, SLINKs are used for all relations between events in subordination structures (

Table 5). SLINK *relTypes* include the value *modal* for references to a possible world; *evidential* and *neg_evidential* for connections of a reporting or perception event to its argument; *factive* and *counter_factive* in relations that imply something about the veracity of an argument; and *conditional* between verbs in conditional and apodosis clauses.

relType	Example
modal	η λύση αυτή προϋποθέτει το συμβιβασμό των 2 πλευρών
evidential	είπε ότι αγόρασε τα βιβλία
neg_evidential	αρνήθηκε ότι χτύπησε το σκυλάκι
Factive	κατάφεραν να το αποκτήσουν
counter_factive	ματαίωσαν τη συμφωνία
conditional	αν προκριθούν στον τελικό, θα πάρουν και τον τίτλο

Table 5 SLINK relation types and examples

4. Conclusions and Future Work

We have presented an ongoing effort for the creation of a Greek Event Annotated Corpus, which has also been annotated for temporal expressions. The annotation was based on a TimeML annotation scheme adapted to the Greek language. Next steps in this line of research include annotation of temporal, aspectual and subordination links between events and temporal expressions. Prokopidis et al. (2009) have reported on work for the development of a TIMEX recognizer. Based on the annotation effort presented in the current paper, we plan to augment our pipeline of NLP tools with an event recognizer. Besides the temporal aspect of events, we are currently experimenting with the creation of a spatial annotation scheme.

GENDER ASSIGNMENT AND GENDER AGREEMENT IN CHILD GREEK L2¹

Irini Konta

Aristotle University of Thessaloniki, Greece

ekonta@lit.auth.gr

ABSTRACT

The present study investigates the performance of Turkish-speaking child L2 learners of Greek of different proficiency levels on gender assignment and gender agreement in Greek compared to monolingual controls. Results indicate that performance increases with increased proficiency level, although accuracy levels of even advanced child L2 learners on gender agreement remain relatively low. Furthermore, morpho-phonological cues seem to play a more important role in the gender assignment task, while semantic cues are significant in the gender agreement task, as they affect all participant groups' performance in the latter task.

Keywords: child L2 acquisition, gender assignment, gender agreement, morpho-phonological cues, semantic cues

1. Introduction

Gender acquisition is considered to be particularly difficult for adult L2 learners. According to the Failed Functional Features Hypothesis grammatical gender is impossible to acquire if the L1 does not have grammatical gender (Hawkins and Franceschina 2004). Another group of researchers claims that adult L2 learners can acquire gender, as their performance increases with increased proficiency level, and that they may have the abstract gender representations but experience a mapping problem between abstract features and their surface forms (White et al. 2004). Recently it has been suggested that child L2 acquisition may also differ from L1 acquisition when age of onset of acquisition is later than 4 years (Meisel 2009) or when input is below a certain threshold (Unsworth 2008). It has even been suggested that L2 children may have intact underlying representations but experience mapping problems (Chondrogianni et al. 2011).

Although the difficulty in distinguishing between gender assignment and gender agreement is acknowledged, researchers often use the gender of the determiners in order to tap on gender assignment and the gender of the adjectives in order to tap on gender agreement. There is evidence that both L2 children and adults perform better on determiners than adjectives, as in the latter case they need not only possess the correct gender specifications but also retrieve the correct adjective, which is more cognitively demanding (Montrul and Potowski 2007, Dewaele and Véronique 2001).

The role of linguistic variables on gender acquisition has also been examined, although the picture is not very clear. There are indications that in gender assignment L2 learners rely primarily on morpho-phonological rules based on noun endings (Holmes and de la Bâtie 1999) although according to another study semantic cues also play some role as L2 learners perform better when morpho-phonological and semantic cues coincide (Oliphant 1998). On the other hand, semantic cues (natural gender) have been found to facilitate processing of gender agreement for both native speakers and L2 learners, while morpho-phonological cues had facilitatory effects only for native speakers (Alarcón 2009). Furthermore, studies using error induction procedures have shown that native speakers of Italian and French make more gender agreement errors when there is a discrepancy between natural and grammatical gender (Vigliocco and Franck 2001).

¹ This research was carried out as part of the author's PhD dissertation for which she has received a grant from the State Scholarships Foundation of Greece.

Turning to the two languages relevant to the present study, Turkish is a language without grammatical gender, whereas Greek has a tripartite gender distinction: masculine, feminine, neuter. Grammatical gender in Greek can be, to some extent, computed on the basis of semantic and morpho-phonological properties of nouns (Anastasiadi-Symeonidi and Chila-Markopoulou 2003). More specifically, it has been claimed that certain noun endings are prototypically masculine, feminine or neuter. On the other hand, [+animate] masculine nouns with masculine referents and [+animate] feminine nouns with feminine referents are semantically prototypical, whereas [-animate] masculine and feminine nouns are semantically non-prototypical, while the inverse holds for neuter nouns: [-animate] neuter nouns are semantically prototypical and [+animate] neuter nouns are semantically non-prototypical, as in this case there is a clash between natural and grammatical gender.²

Acquisition studies in L1 (Gavriilidou and Efthymiou 2003) and L2 Greek (Varlokosta 2005) have shown that both Greek preschool children and Turkish children acquiring Greek as an L2 perform better in gender assignment when nouns are prototypical with respect to gender, i.e. when morpho-phonological and semantic cues coincide. Furthermore, Gavriilidou and Efthymiou (2003) claim that preschool children rely primarily on morpho-phonological cues –and only secondarily on semantic cues– when assigning gender to Greek nouns³ as well as that there is gradation of prototypicality even within the prototypical categories⁴. Additionally, studies on gender agreement in L2 Greek indicate that the neuter form of the adjective, which is considered to be the default and the most easily accessible, is usually overgeneralized, although another main type of error attested consists in the phonological matching between nominal and adjectival endings (Agathopoulou et al. 2008). Finally, it should be noted that native speakers of Greek sometimes perform semantic instead of grammatical gender agreement when there is a discrepancy between the two (Chila-Markopoulou 2003).

In this study we examine (a) gender assignment as well as gender agreement in Turkish-speaking child L2 learners of Greek and (b) the role of different linguistic variables (type of ending versus semantic prototypicality) in the two tasks. The question of whether the L2 learners' performance should be attributed to their underlying knowledge or to performance issues is also touched upon.

More specifically, the following research hypotheses have been formulated:

- (a) Native speakers of Greek (NS) will have higher accuracy than child L2 learners of Greek (NNS) on both tasks (Montrul and Potowski 2007).
- (b) NNS' accuracy will increase according to their proficiency level (White et al. 2004).
- (c) If NNS have acquired gender representations, but experience mapping-accessibility problems, they will score higher on gender assignment than gender agreement, which is a cognitively more demanding task (Montrul and Potowski 2007).
- (d) NNS will have higher accuracy on semantically prototypical nouns (Gavriilidou and Efthymiou 2003, Varlokosta 2005).
- (e) There might be a differential effect of the linguistic variables in the two tasks: noun ending might play a more important role in gender assignment (Holmes and de la Bâtie 1999) and semantic prototypicality in gender agreement (Alarcón 2009).

2. Method

2.1 Materials

Two off-line tasks were employed, one to assess gender assignment and one to assess gender agreement. Figure 1 presents an example from the gender assignment task on the left and an example from the gender agreement task on the right. In the gender assignment task, the participants were given pictures accompanied by the nouns depicted on the pictures and were asked to choose the correct definite article for each noun. In the gender agreement task, the participants were presented with two pictures showing the same referent. The two pictures of the referents differed with respect to a specific property, for example size (e.g. a big umbrella and a small umbrella). One of the pictures was circled and the participants had to use an adjective to refer to the circled referent. Both tasks included the same nouns. In particular, 64 nouns with 8 different endings (8X8=64), 3 typically masculine (*-os*, *-as*, *-is*), 2 typically feminine (*-a*, *-i*) and 3 typically neuter (*-o*, *-i*, *-ma*), were used in both tasks. Half the nouns in

² The notion of semantic prototypicality extends beyond that of natural gender, but we leave this aside, since it goes beyond the purpose of the present paper.

³ This claim is partly based on the fact that L1 children often assign feminine gender to neuter nouns ending in *-i*.

⁴ They claim *inter alia* that masculine nouns ending in *-os* are more prototypical than those ending in *-as*, *-is*.

each ending, except ending *-ma*⁵, (4x7=28) were semantically prototypical, i.e. [+human] masculine and feminine nouns and [-animate] neuter nouns, and half were semantically non-prototypical, i.e. [-animate] masculine and feminine nouns and [+human] neuter nouns. All nouns were prototypical in terms of the morphological endings. There are however two endings that could pose additional problems for L2 learners: a) ending *-i* can mark either feminine or neuter nouns, although the ambiguity is resolved by different graphemes (<η> and <ι> respectively) and b) ending *-ma* (neuter) could get confused with ending *-a* (feminine).

Figure 1 Examples from the gender assignment and the gender agreement task

2.2 Participants

41 native speakers of Greek (NS) and 125 Turkish-speaking learners of Greek (NNS) participated in both tasks. They were all first and second year students (aged 12-14) in four high-schools of rural areas in Western Thrace. Proficiency in Greek was measured by means of a written proficiency test, which was part of the test *Let's Speak Greek III* (Tzevelekou et al. 2003) that has been designed in order to examine Turkish-speaking children's proficiency in L2 Greek. The test was administered to both NS and NNS. NS had a mean of 21 out of a maximum of 24 (SD=2, range=17-24). NNS were divided into four proficiency levels⁶ based on the mean and the SD of the NS group: a) advanced, range 17-24, mean=19, SD=2, n=24, b) high intermediate, range 13-16, mean=15, SD=1, n=28, c) low intermediate, range 9-12, mean=11, SD=1, n=40, d) beginners, range 1-8, mean=6, SD=2, n=33. None of the L2 adolescents had parents who were native speakers of Greek. Their age of onset of acquisition wasn't examined, but Turkish-speaking children growing up in these areas of Greece are usually first exposed to Greek when they enter Primary school.

2.3 Procedure

Participants were examined orally on an individual basis by the author. The slides with the pictures and the nouns were presented on a computer screen in the form of a power-point presentation. The researcher read the questions, which were also written on the slides. The participants' answers were written down by the researcher on an answer sheet. There were three practice trials for the gender assignment task and eleven practice trials for the gender agreement task, in which the participants encountered all the adjectives used in the task. Both tasks were untimed.

⁵ All nouns ending in *-ma* were [-animate], thus semantically prototypical.

⁶ As only part of the original test was administered, NNS could not be classified according to the range of proficiency levels specified for that test. Consequently, we relied on the NS mean score and SD in order to assign them to different proficiency levels, as NNS who score within two SDs of the NS mean are generally considered to be advanced.

2.4 Data Analysis

In the gender assignment task correct responses were scored when the participants selected the correct definite article. In the gender agreement task correct responses were scored when the participants produced an adjective that agreed in gender with the corresponding noun, irrespective of whether it was suitable in terms of meaning and of whether there were any other errors in the form of the adjective. One item⁷ was excluded from the analysis due to inconsistent responses of the NS in both tasks.

Participants received 1 point for each correct response. Each participant's accuracy score, i.e. the sum of correct responses (maximum=63), was calculated for each task. Additionally, the percentage of correct responses of each participant for each ending as well as for prototypical and non-prototypical nouns were also calculated.

In order to test hypotheses (a) and (b), one-way ANOVAs with accuracy score as the dependent variable and group of participants as the independent variable were conducted for each task. When there was a main effect of group, post-hoc Games-Howell comparisons followed up in order to spot the significant differences that existed between groups. All differences reported were significant at $p < .05$ or higher. Hypothesis (c) was tested by means of separate paired-samples t-tests that were conducted for each group of participants and examined whether accuracy scores were higher for the gender assignment than for the gender agreement task. Separate paired-samples t-tests were also used to examine whether the percentage of correct responses of each group of participants was higher for semantically prototypical versus semantically non-prototypical nouns in each task⁸, cf. hypothesis (d). Finally, in order to test for the effect of type of ending on performance on gender assignment and gender agreement, cf. hypothesis (e), separate one-way ANOVAs for each task and each group of participants were conducted with type of ending (*-os* vs *-as* vs *-is* vs *-a* vs *-i*(fem) vs *-o* vs *-i*(neut) vs *-ma*) as the independent variable and percentage of correct responses as the dependent variable. Whenever there was a significant main effect of type of ending, post-hoc Bonferroni comparisons were conducted in order to test for significant differences in accuracy levels between individual endings. Significance level was once again set at $p < .05$.

3. Results

Figure 2 presents accuracy (%) of all groups of participants in both tasks. Native speakers are at ceiling on the gender assignment task, whereas they perform 1% of errors on the gender agreement task. The accuracy levels of NNS of all proficiency levels seem relatively low. Advanced NNS, however, seem to have acquired gender specifications as they perform above 90% on the gender assignment task, but lag behind on the agreement task. Furthermore, all groups of participants have higher accuracy on gender assignment than on gender agreement and there seems to be improvement with increased proficiency for both tasks.

These results were statistically significant. More specifically, there was a main effect of group for both the gender assignment task ($F(4,161)=74.47$, $p=.000$) and the gender agreement task ($F(4,161)=196.83$, $p=.000$). Post-hoc comparisons revealed that in both tasks (a) NS had higher accuracy than all groups of NNS, (b) advanced NNS had higher accuracy than all other groups of NNS, (c) high intermediate and low intermediate NNS had higher accuracy than beginners, but (d) did not significantly differ from each other. It is however important to note that in the gender agreement task the difference between high intermediate and low intermediate NNS was approaching significance ($p=.055$). Finally, all groups of participants performed better on gender assignment than gender agreement ($t(32)=5.89$, $p=.000$, for beginners, $t(39)=11.34$, $p=.000$ for low intermediate, $t(27)=8.14$, $p=.000$ for high intermediate, $t(23)=7.29$, $p=.000$ for advanced NNS, $t(40)=4.02$, $p=.000$ for NS).

⁷ The excluded noun is the masculine noun *τοιχος* "wall", which apparently got confused with the neuter noun *τείχος*, which has a similar meaning.

⁸ Neuter nouns ending in *-ma* were not included in this analysis, as there were not any semantically non-prototypical nouns in that ending.

Figure 2 Accuracy (%) on gender assignment and gender agreement

Table 1 presents accuracy of each group of participants on each ending and according to the semantic prototypicality of nouns for the gender assignment task. All groups of NNS seem to perform better on semantically prototypical than on semantically non-prototypical nouns. Additionally, they all seem to obtain their lowest score on words ending in *-ma* and they also seem to perform worse on feminine nouns in *-i* than on feminine nouns in *-a* and worse on neuter nouns in *-i* than on neuter nouns in *-o*.

Statistical analyses revealed that beginners, low intermediate and high intermediate NNS had higher accuracy, i.e. higher percentage of correct responses, on semantically prototypical than on semantically non-prototypical nouns ($t(32)=7.18$, $p=.000$, $t(39)=8.33$, $p=.000$ and $t(27)=6.52$, $p=.000$ respectively). The difference was not significant for NS ($t(40)=0$, $p=1$) and it was only approaching significance for advanced NNS ($t(23)=1.93$, $p=.066$) probably due to ceiling effects. Additionally, there was a main effect of ending for all groups of NNS ($F(4.39,140.52)=6.96$, $p=.000$ for beginners, $F(3.68,143.50)=17.88$, $p=.000$ for low intermediate, $F(4.05,109.40)=4.67$, $p=.002$ for high intermediate, $F(1.67,38.45)=4.73$, $p=.02$ for advanced NNS) but not for NS ($F(7,280)=.85$, $p=.54$).

According to post-hoc analyses, beginners' accuracy was higher on:

- (a) masculine nouns in *-os* than on masculine nouns in *-as* and *-is*,
- (b) feminine nouns in *-a* than on masculine nouns in *-is* and neuter nouns in *-i* and *-ma*,
- (c) feminine nouns in *-i* than on masculine nouns in *-is*.

Low intermediate NNS had higher accuracy on:

- (a) masculine nouns in *-os* than on masculine nouns in *-as* and *-is*, feminine nouns in *-i* and neuter nouns in *-o*, *-i*, *-ma*,

- (b) feminine nouns in *-a* than on masculine nouns in *-is*, feminine nouns in *-i* and neuter nouns in *-i* and *-ma*,
- (c) masculine nouns in *-as* than on masculine nouns in *-is* and neuter nouns in *-ma*,
- (d) feminine nouns in *-i* than on neuter nouns in *-ma* and
- (e) neuter nouns in *-o* than on neuter nouns in *-i* and *-ma*.

High intermediate NNS had higher accuracy on:

- (a) masculine nouns in *-os* than on masculine nouns in *-is* and neuter nouns in *-i*,
- (b) feminine nouns in *-a* than on neuter nouns in *-o* and *-i*.

Unexpectedly, performance on ending *-ma* was not significantly different from performance on any other ending, although accuracy on that ending was particularly low (67%). Advanced NNS had higher accuracy⁹ on:

- (a) masculine nouns in *-os* and feminine nouns in *-a* than on feminine nouns in *-i* and neuter nouns in *-ma*,
- (b) masculine nouns in *-as* and *-is* and neuter nouns in *-o* than on neuter nouns in *-ma*.

It seems thus that all groups of NNS exhibited a similar pattern of performance: they all scored worse on ending *-ma*, although the difference was not always reflected in the statistics, and all groups, except advanced NNS, also scored worse on ending *-is*. Accuracy on neuter and feminine nouns in *-i* was also relatively low.

Table 1 Correct performance in the gender assignment task (%). SDs in parentheses

Table 2 presents accuracy for each participant group on each ending and according to the semantic prototypicality of nouns for the gender agreement task. The NS seem to perform errors almost exclusively on semantically non-prototypical neuter nouns in *-o* and *-i*, i.e. when there is conflict between natural and grammatical gender. All groups of NNS have higher accuracy on semantically prototypical than on semantically non-prototypical nouns and the differences seem bigger than in the gender assignment task, as performance on non-prototypical nouns is extremely low for beginners, low intermediate and high intermediate NNS and remains relatively low even for advanced NNS. Finally, NNS exhibit one of their best scores on nouns ending in *-ma*, contrary to what has been observed in the gender agreement task.

⁹ For advanced NNS, Bonferroni comparisons failed to reveal any significant differences among different endings. For that reason, multiple comparisons without any adjustment (Least Significant Difference) were conducted.

Gender	Ending	Semantic Prototypicality	Beginners	Low Intermediate	High Intermediate	Advanced	NS

Table 2 Correct performance in the gender agreement task (%). SDs in parentheses.

Statistical analyses revealed that all groups of participants had higher accuracy on semantically prototypical than on semantically non-prototypical nouns ($t(32)=9.44$, $p=.000$ for beginners, $t(39)=21.14$, $p=.000$ for low intermediate, $t(27)=17.71$, $p=.000$ for high intermediate, $t(23)=6.75$, $p=.000$ for advanced NNS and $t(40)=4.19$, $p=.000$ for NS). Additionally, there was also a main effect of ending for all groups of participants ($F(3.43,109.82)=19.53$, $p=.000$ for beginners, $F(2.59,101.17)=28.15$, $p=.000$ for low intermediate, $F(3.16,85.25)=13.81$, $p=.000$ for high intermediate, $F(3.22,74.11)=3.26$, $p=.02$ for advanced NNS and $F(7,280)=7.93$, $p=.000$ for NS). Post-hoc comparisons revealed that beginners had higher accuracy on:

- neuter nouns ending in *-ma* than on nouns in any other ending,
- masculine nouns in *-is* than on masculine nouns in *-as* and feminine nouns in *-a*,
- neuter nouns in *-o* than on masculine nouns in *-as* and feminine nouns in *-a* and *-i*,
- neuter nouns in *-i* than on feminine nouns in *-a*.

Low intermediate NNS exhibited higher accuracy on:

- neuter nouns in *-ma* than on nouns in any other ending,
- masculine nouns in *-os* and neuter nouns in *-o* than on masculine nouns in *-as* and feminine nouns in *-a* and *-i*,
- masculine nouns in *-as* and neuter nouns in *-i* than on feminine nouns in *-i*,
- masculine nouns in *-is* than on feminine nouns in *-a* and *-i*.

High intermediate NNS performed better on:

- neuter nouns in *-ma* than on nouns in any other ending,
- masculine nouns in *-os* than on feminine nouns in *-i*,
- neuter nouns in *-o* than on feminine and neuter nouns in *-i*.

Advanced NNS performed better on:

- neuter nouns in *-ma* than on neuter nouns in *-i*,
- masculine nouns in *-is* than on masculine nouns in *-as*.

NS exhibited higher accuracy on masculine nouns in *-os* and *-as* and feminine nouns in *-a* and *-i* than on neuter nouns in *-o*, due to the fact that they scored low on semantically non-prototypical neuter nouns ending in *-o*. It seems thus that there is a common pattern in the performance of all groups of NNS in that they all exhibit their best performance on neuter nouns ending in *-ma*. What is particularly interesting is the fact that this pattern of performance is very different from the pattern exhibited in gender assignment, where NNS obtained low scores on nouns ending in *-ma*.

4. Discussion

Our research hypotheses have been confirmed to a large extent. NS have higher accuracy than NNS on both tasks and NNS' performance improves according to their proficiency level. Furthermore, all groups of participants (even NS) perform better on gender assignment than gender agreement, indicating that some of the problems the NNS face may be related to performance issues. It is evident that all groups of NNS have not acquired the correct gender specifications yet, as their scores on gender assignment are relatively low. Advanced NNS however seem to have acquired the underlying gender representations, as they reach the 90% criterion in the gender assignment task, and seem to be encountering performance issues in the gender agreement task. This finding is not surprising because this latter task is more demanding, as the participants need not only perform gender agreement but also select the appropriate adjective. The finding that L2 children perform better on gender assignment (i.e. determiners) than gender agreement (adjectives) is also corroborated by previous studies (cf. Montrul and Potowski 2007).

Turning to the role of the linguistic variables in the two tasks, there are effects of type of ending and semantic prototypicality for both tasks. More specifically, the type of ending affected all L2 groups' responses in the gender assignment task and all groups' responses (even NS) in the gender agreement task. Furthermore, semantic prototypicality had an impact on all L2 groups' performance except for advanced NNS, for who it only approaches significance, in the gender assignment task and on all groups' performance in the gender agreement task. Moreover, the difference in accuracy between semantically prototypical and semantically non-prototypical nouns that share the same endings is bigger in the gender agreement than in the gender assignment task, as in the former task the NNS' scores on semantically non-prototypical nouns are extremely low. It seems thus at first sight that both morpho-phonological and semantic cues play an important role in both tasks and that their role is more pronounced in the gender agreement task as they have a global effect on all groups' accuracy in the latter task.

Closer inspection reveals a different picture though. The pattern of performance of the NNS with respect to noun endings is completely different in the two tasks. In the gender assignment task all groups of NNS exhibit particularly low scores on neuter nouns ending in *-ma* and relatively low scores on feminine and neuter nouns ending in *-i*, while beginners, low and high intermediate NNS also exhibit particularly low scores on masculine nouns ending in *-is*. In the gender agreement task on the other hand, all groups of NNS exhibit particularly high scores on neuter nouns ending in *-ma*, beginners and low intermediates also exhibit low scores on feminine nouns in *-a* and *-i* and all groups of NNS except high intermediate have low accuracy on masculine nouns in *-as*. Finally, NS perform relatively poorly on neuter nouns in *-o*. The pattern of performance of NNS in the gender assignment task can be explained if we assume that they rely primarily on morpho-phonological rules for assigning gender to unknown nouns. Neuter nouns ending in *-ma* are more opaque with respect to gender, as ending *-a* usually marks feminine nouns, and ending *-i* is not transparent either in oral speech as it can denote either feminine or neuter nouns. Finally, low scores on masculine nouns in *-is* can be accounted for by assuming that NNS got confused by the phoneme [i] of the ending, which, as stated above, marks feminine and neuter nouns. It is important to note that Gavrilidou and Efthymiou (2003) also report that L1 children assigned feminine gender to neuter nouns ending in *-i* to a large extent and also exhibited lower accuracy on masculine nouns ending in *-as* and *-is* than on masculine nouns ending in *-os*. Furthermore, their conclusion that L1 preschool children rely primarily on morpho-phonological cues and only secondarily on semantic cues is partly based on these findings. The performance in the gender agreement task on the other hand cannot be explained if we assume reliance on morpho-phonological rules. Rather, it seems that performance on different type of endings in this task is interrelated with other factors, such as semantic prototypicality and gender. The pattern of performance of NS implies that they performed worse when there was discrepancy between natural and grammatical gender, i.e. on semantically non-prototypical neuter nouns. This finding is not surprising given the fact that there are studies indicating that NS sometimes perform semantic agreement when there is clash between natural and grammatical gender (cf. Vigliocco and Franck 2001, Chila-Markopoulou 2003). The high performance of NNS on neuter nouns in *-ma* can be attributed to the fact that they overgeneralized the neuter form of the adjective for [-animate] nouns, which is reasonable based on the fact that L2 learners of Greek often overgeneralize the neuter form of the adjectives (cf. Agathopoulou et al. 2008, among others). Furthermore, poor performance of low proficiency levels of NNS on feminine nouns in *-a* and *-i* can be accounted for by the problems the L2 learners faced with the feminine form of the adjective. Finally, the NNS' low performance on masculine nouns in *-as* needs to be explained in more detail. One could assume that they rely on morpho-phonological cues, as Gavrilidou and Efthymiou (2003) also noted that L1 children had lower accuracy on masculine nouns

in *-as* and attributed the fact to morpho-phonological factors and more specifically to the thematic vowel *-a* of these nouns which coincides with the feminine ending *-a*. We do not, however, believe that this is the case, as there are no other indications of reliance on morpho-phonological cues in this task. On the contrary, we believe that more idiosyncratic factors may explain this pattern of performance, as 3 out of the 4 semantically non-prototypical nouns in *-as* yielded a color adjective and the neuter form of the color adjectives is most commonly used.

Concluding, it seems that morpho-phonological cues had a major impact in the gender assignment task (importantly, Gavriilidou and Efthymiou 2003 also tested gender assignment), whereas semantic cues played an important role in both tasks but affected the participants' performance more crucially in the gender agreement task. The fact that semantic prototypicality influenced the performance of both NS and NNS in gender agreement indicates that accuracy in that task is related to performance issues. Furthermore, the indications that the neuter form of the adjective, which is the most easily accessible form, is overgeneralized also point to mapping-accessibility problems. The present study thus indicates that some of the L2 children's agreement errors should be attributed to performance issues, although, clearly, more evidence is needed in order to reach such a conclusion.

ABSTRACT

The aim of our study is to examine the diachronic development of a set of anticausative verbs with respect to the frequency of ACT/NACT (active/nonactive) Voice morphology as well as their participation in causative (transitive) and anticausative structures. We investigate diachronic differences between verbs that synchronically mark anticausative with ACT and other verbs which express anticausative either with ACT or NACT. Significant differences between the verbs are shown in the previous periods with respect to ACT/NACT distribution, while anticausative readings show a similar diachronic development of Voice marking regardless of the Lexical Conceptual Structure (LCS) of the verb class. We propose that this is caused by a change in the features of NACT morphology from a period when syntactic movement (internal Merge) of an internal argument to the subject position needs to be morphologically marked with (NACT) Voice morphology to the stage attested today where syntactic movement does not need to be marked with Voice morphology.

Keywords: Voice morphology, anticausatives, verbs of two forms (“δίτυπιάς”), diachrony

1. Introduction

The aims of our study are to investigate (a) why anticausative readings are primarily expressed with active (ACT) morphology in Modern Greek (MG) verbs, and (b) why, in earlier periods, the active/nonactive (ACT/NACT) alternation was consistent while in MG the relevant alternation appears to be relatively inconsistent. To approach these aims, we will examine the diachronic development of a set of anticausative verbs with respect to the frequency of (a) ACT/NACT Voice morphology and (b) their participation in causative (transitive) and anticausative structures. In this respect, we will search for diachronic differences between verbs that synchronically mark anticausative with ACT exclusively and verbs that express anticausative readings either with ACT or NACT morphology (verbs of two forms, “δίτυπιάς”, according to Theophanopoulou-Kontou 2004).

The outline of the study is as follows: (i) we present the MG classes of anticausatives based on Voice marking and our selection of verbs that either retain the ACT form in both the causative and anticausative version of the alternation or express anticausative either with ACT or NACT. (ii) We examine the frequency of ACT and NACT with these verbs diachronically, the frequency of anticausative interpretations, the transitive uses and the role of the animacy feature on the syntactic subject. (iii) We compare the development of the verbs that are only ACT in MG with the development of the verbs that can have ACT or NACT Voice morphology (*katharise/katharistike* ‘cleaned’). Our proposal will be that ACT spread (from the prototypical use of ACT in unergatives) to all verbs with single-argument representation in the syntactic structure due to or in parallel with a change in the properties of NACT.

1.1 Modern vs. Ancient Greek ACT and NACT uses

With regard to Voice marking, there are three classes of verbs with anticausative readings in MG: (i) verbs that are marked with ACT (*eklise* 'closed-ACT'); (ii) verbs that are marked either with ACT or with NACT (*lerose/lerothike* 'got-dirtied-ACT/NACT'); (iii) verbs that are marked with NACT (*skistike* 'got-torn-NACT').

- (1) *I porta eklise (apo ton aera).*
ART.NOM.SG door:NOM.SG close:ACT.PST.PFV.3SG (by ART.ACC.SG wind:ACC.SG)
'The door was closed (by the wind).'
- (2) *Ta ruha lerosan/lerothikan apo ti boja.*
ART.NOM.PL cloth:NOM.PL get-dirty:ACT/NACT.PST.PFV.3PL by ART.ACC.SG paint:ACC.SG
'The clothes got dirty from the paint.'
- (3) *I simea skistike apo ton aera.*
ART.NOM.SG flag:NOM.SG get-torn:NACT.PST.PFV.3SG by ART.ACC.SG wind:ACC.SG
'The flag got torn by the wind.'

Verbs that denote both internally (*sapise* 'rotted') and externally-caused (*eklise* 'closed', *espase* 'broke') change of state are included in the first class, while externally-caused change of state verbs are included in the second (verbs of two forms/"ditipia" verbs; *katharise* 'cleaned', *tsalakose* 'crumpled', *tripise* 'pierced') and the third class (only NACT; *afksithike* 'increased', *miothike* 'diminished', *skistike* 'got-torn') (Theophanopoulou-Kontou 1983-4, 2004, Tsimpli 1989, 2006, Alexiadou & Anagnostopoulou 2004, Roussou 2009, Alexiadou 2010, Manzini, Roussou & Savoia [to appear]). The third class is consistent and diachronically stable in the use of NACT as a transitivity change marker (Lavidas 2009), and will not be examined further in the present study.

The general picture shows that anticausative verbs differ with respect to (i) Voice (only ACT in causative and anticausative vs. optionality in the use of ACT/NACT in the anticausative form¹) and (ii) Lexical Conceptual Structure (LCS) (internally and externally caused change of state verbs in the first class vs. only externally caused change of state verbs in the other classes). On the other hand, the diachronic pattern of both classes is similar, since both started with only NACT for anticausative readings and ACT strengthened later in their development (Lavidas 2009). In this article, we will examine the role of the animacy feature and the presence or absence of a correlation between the spread of ACT in anticausatives and the changes in the distribution of ACT/NACT regardless of readings, the LCS differences, and the frequencies of causative vs. anticausative uses. Diachronic differences which do not necessarily pertain to Voice marking can be observed within verb classes as well: minimal changes in the stem (*vrasso/vratto* – *vrazo* 'boil') are attested, different stems are used in parallel for some period of time with only one surviving eventually (*tēkō* / *tēkomai* – *liono* 'melt'), and, finally and most frequently, prefixed forms of these verbs are attested in earlier periods but are lost now. We exclude prefixed verb forms from our present study and examine different stems separately.

We initially considered the change in the use of NACT morphology as a potential effect of the differences in the LCS of these verbs (one-place predicates vs. two-place predicates; Levin 1993, Levin and Rappaport Hovav 1995, 2005); however, *klino* and *sapizo* both belong to the first class in terms of disallowing NACT morphology although *klino* is an externally-caused change of state verb while *sapizo* an internally-caused one. Evidence for the differences in the LCS can be provided (1) by considering subject animacy: one-place predicates (internally-caused verbs) prefer inanimate subjects regardless of Voice marking while two-place predicates (externally-caused verbs) should show an interaction between Voice morphology and animacy (they should prefer animate subjects when marked ACT) – and (2) by considering the frequency of transitive uses: two-place predicates should be more frequent in transitive uses than one-place predicates.

In AG Voice morphology changes were consistent in that all anticausative classes of MG were marked with NACT² when the structure was anticausative while all causative uses of the same verbs were marked as ACT (even though NACT was allowed in other cases of transitive uses; Table 1)

¹ but only with inanimate subjects ("ditipias" verbs).

² Ancient Greek has a complex nonactive voice system: "middle" (or "mediopassive") endings in all tenses, and additional "passive" suffixes only in the Aorist and Future tense. "Middle"/"mediopassive" endings are not excluded from a passive reading, and "passive" endings can be used with a non-passive reading, i.e. with an anticausative interpretation or even in a transitive construction. Mainly for this reason (cf. also Lavidas 2009: 79), we call "nonactive" all endings that are different from the active endings and are traditionally called "middle" (or "mediopassive") or "passive".

(Lavidas 2009). NACT in AG can be seen as a marker of the internal argument displacement (or derived subject) with no reference to the presence or absence of an external argument.

AG verbs	Voice morphology
a. all three classes of anticausatives	NACT <i>etákēn, etēkhthēn</i> ‘melted’ <i>ekathērámēn, ekathárthēn</i> ‘cleaned’ <i>ēuksēhēn</i> ‘increased’
b. transitives	both ACT and NACT (self-beneficent interpretation) <i>paraskeuázō</i> <i>naûn</i> <i>prepare:ACT.PRS.1SG</i> <i>ship:ACC.SG</i> <i>‘I prepare a ship.’</i> <i>paraskeuázomai</i> <i>naûn</i> <i>prepare:NACT.PRS.1SG</i> <i>ship:ACC.SG</i> <i>‘I prepare a ship for myself.’</i>
c. causatives	only ACT
d. passives	NACT (few instances of ACT)
e. reflexives	NACT

Table 1 Voice morphology in AG³

2. The Data

The verbs examined are: *klino* ‘close’, *stegnono* ‘dry’, *liono* ‘melt’, *sapizo* ‘rot’, *vrazo* ‘boil’ (Voice non-alternating anticausatives/first class). Our aim was to look for similarities and differences between them. We compared these Voice non-alternating verbs with a Voice alternating verb (*katharizo* ‘clean’; second class; it exhibits “ditipia” i.e. both ACT and NACT in MG) to establish differences diachronically. The periods examined are AG, Hellenistic-Roman Greek (HRG), Medieval Greek (MedG) and MG. *Klino* ‘close’ is considered a Voice non-alternating anticausative in MG although we will show that it is different from the other verbs of the first class and more similar to *katharizo* ‘clean’ (which is a “ditipias” verb) in LCS (both synchronically and diachronically) and the related variables (animacy and transitive uses). Hence, the four parameters of our study are: frequency of ACT vs. NACT Voice morphology, Voice marking with anticausative reading, subject animacy, and frequency of transitive uses.

Since our aim is to compare results from different corpora, we decided to base our study on the whole Institute for Language and Speech Processing (hence ILSP) corpus, available on <http://hnc.ilsp.gr>⁴ and the whole Thesaurus Linguae Graecae (TLG) corpus, available on <http://www.tlg.uci.edu/> (written register, mainly formal):

(i) MG: ILSP corpus;

(ii) AG (8BC – 3BC), HRG (3BC – AD4), MedG (mainly AD12 – AD15): TLG online corpus; AD5 – AD11: early medieval texts were also included but only in an attempt to find the earliest appearance of ACT marking in anticausatives (and are not further discussed in the present paper).

Of course, a lot of limitations and methodological difficulties can be met in such studies: for example, the constant updating of both corpora makes searches not completely repeatable; the small number of examples of the targeted interpretations forces us to collect raw data from the TLG and ILSP as a whole, i.e. not to be sensitive to register, geographical location etc, and not to be fully representative of vernacular Greek. Nevertheless, some relevant trends can be observed. Furthermore, we examined sentences with only 3rd person (singular or plural) forms of these verbs (to avoid any possible person effect) and we had to ignore data from the AG period since most of our verbs (with the specific meanings) first appeared in HRG.

³ Cf., among many others, Goodwin 1978 [1894], Kühner & Gerth 1963 [1898-1904], Gildersleeve 1900, Stahl 1907, Smyth 1984 [1920], Meillet & Vendryes 1924, Humbert 1945, Schwyzler 1943 [1942], Schwyzler & Debrunner 1950, Jankuhn 1969, Duhoux 2000², Allan 2003, Luraghi 2010.

⁴ The ILSP corpus seems to be closer to the TLG corpus that contains a variety of registers, most of them (written and) formal.

Verbs	First Attestation
<i>stegnóō/stegnóno</i>	HRG
<i>tēkō</i>	Homeric Greek; ‘melt’, often prefixed <i>eks-</i> , <i>en-</i> , <i>sun-</i>
<i>leiōō/óno</i>	HRG; mainly with the meaning ‘make smooth, be polished, smoothed, pound fine, emulsify’ / Medieval Greek: ‘melt’
<i>sēpō</i>	Homeric; ‘make rotten’
<i>sapízo</i>	MedG; formed on the basis of the AG 3pl Aorist <i>esápēsan</i>
<i>vráso/tto/zo</i>	HRG; meaning ‘shake violently, throw up’ (cf. MG: <i>ksevrázi/ete</i>), and ‘boil’
<i>klíno</i>	AG (<i>kleiō</i>); but most of the examples with a prefix <i>kata-</i> , <i>ek-</i> , <i>apo-</i> , <i>peri-</i> , <i>sun-</i> [we do not include prefixed classes of <i>kleiō</i> in the present data]
<i>katharízo</i>	HRG (we leave the data of <i>kathairō</i> open for future research)

Table 2 Our corpora: dates and limitations

The criteria we used to identify anticausative readings included the presence of PPs or DPs in the dative/genitive (or subordinate clauses) denoting a Cause argument and not an Agent, and the absence of explicit or implicit agentivity on the basis of the context (examples of sentences with anticausative or passive reading are given in 4a and b). Hence, we coded for explicit (PPs, DPs-dative, etc) and implicit (derived from context) cause, Voice morphology, and subject animacy.

(4) a. anticausative reading

katháper kai hai tōn balaneíōn thúrai automátōs
just-as and ART.NOM.PL ART.GEN.PL bath:GEN.PL door:NOM.PL by-themselves
kleíontai
close:NACT.PRS.3PL

‘Just as the doors of the baths close by themselves.’

(Heron Mech., Pneumatica, 1, 39, 16; AD 1)

b. passive reading

kleísthētai tò stómion hōs hupò daktúlōn
close:NACT(PASS).FUT.3SG ART.NOM.SG mouth:NOM.SG as by finger:GEN.PL
tinōn
some:GEN.PL

‘The mouth will be closed as if by some fingers.’

(Galenus Med., De simpl. med. temp. ac fac. xi., 11, 752, 18; AD 2)

Finally, in order to address the question of LCS differences between the two verb classes, we coded for transitive uses of the verbs under discussion (two-place predicates should prefer transitive uses) and subject animacy (animate/inanimate) in the transitive and anticausative uses (two-place predicate should prefer animate subjects with ACT Voice).

3. Results and Discussion

For ease of exposure, we first analyse data with regard to frequency of ACT and NACT Voice marking and then proceed to the analyses of the other variables tested, i.e. anticausative reading with ACT and NACT verb morphology, animacy of the syntactic subject (both with ACT and NACT verb forms) and, finally, frequency of transitive vs. anticausative readings (with ACT verb forms)⁵.

Starting with the distribution of the morphological marking of Voice, the results show that the frequency of ACT Voice morphology increased and NACT decreased throughout the different periods

⁵ When statistical data are provided, MedG corresponds to the period AD12 – AD15 (and not to the Early Medieval subperiod (AD5 – AD11) as well).

examined, as shown in Graphs 1 and 2, although not all of the verbs have the same equal distribution of ACT/NACT⁶:

Graph 1 Diachronic change in the distribution of the ACT vs. NACT Voice morphology (%): the verbs *katharizo* ‘clean’ and *klino* ‘close’

Graph 2 Diachronic change of the distribution of the ACT vs. NACT Voice morphology (%): the verbs *stegno* ‘dry’, *vrazo* ‘boil’ and *sapizo* ‘rot’

All the verbs presented are shown to favour ACT verb marking in MG, though significant differences between the verbs are shown in the previous periods with respect to their distribution. More specifically, *sapizo* and *liono* show a high preference for the NACT over the ACT marking (HRG: $\chi^2=121.786$, $p<.001$ and MedG: $\chi^2=7.200$, $p=.007$; HRG: $\chi^2=72.377$, $p<.01$ and MedG: $\chi^2=14.087$, $p<.001$ respectively). *Stegno* is more like *klino* and *katharizo*: their distribution of (N)ACT uses does not show extreme tendencies in HRG (though *klino* is more used in ACT ($\chi^2=13.535$, $p<.001$), the other two are equally used); all of them present an increase in the use of ACT in MedG ($\chi^2=5.714$, $p=.017$; $\chi^2=4.745$, $p=.029$; $\chi^2=.333$, $p=.564$ respectively), and they are almost exclusively used in ACT in MG ($\chi^2=395.588$, $p<.001$; $\chi^2=3067.404$, $p<.001$; $\chi^2=45.302$, $p<.001$ respectively). *Sapizo* and *liono* are more used in NACT until MedG ($\chi^2=7.200$, $p=.007$; $\chi^2=14.087$, $p<.001$ respectively), but they undergo an

⁶ Due to the differences in the size of the corpora, only relative frequencies are used (i.e., for example, percentage of ACT vs. NACT endings of a verb in a specific period), and not absolute frequencies.

abrupt change in MG and are exclusively used in ACT. *Vrazo* looks like *katharizo* and *klino*, though no significant differences are revealed when non-parametric chi-square tests are conducted, except for MG, where ACT morphology is significantly preferred over the NACT one ($\chi^2=203.848$, $p<.001$).

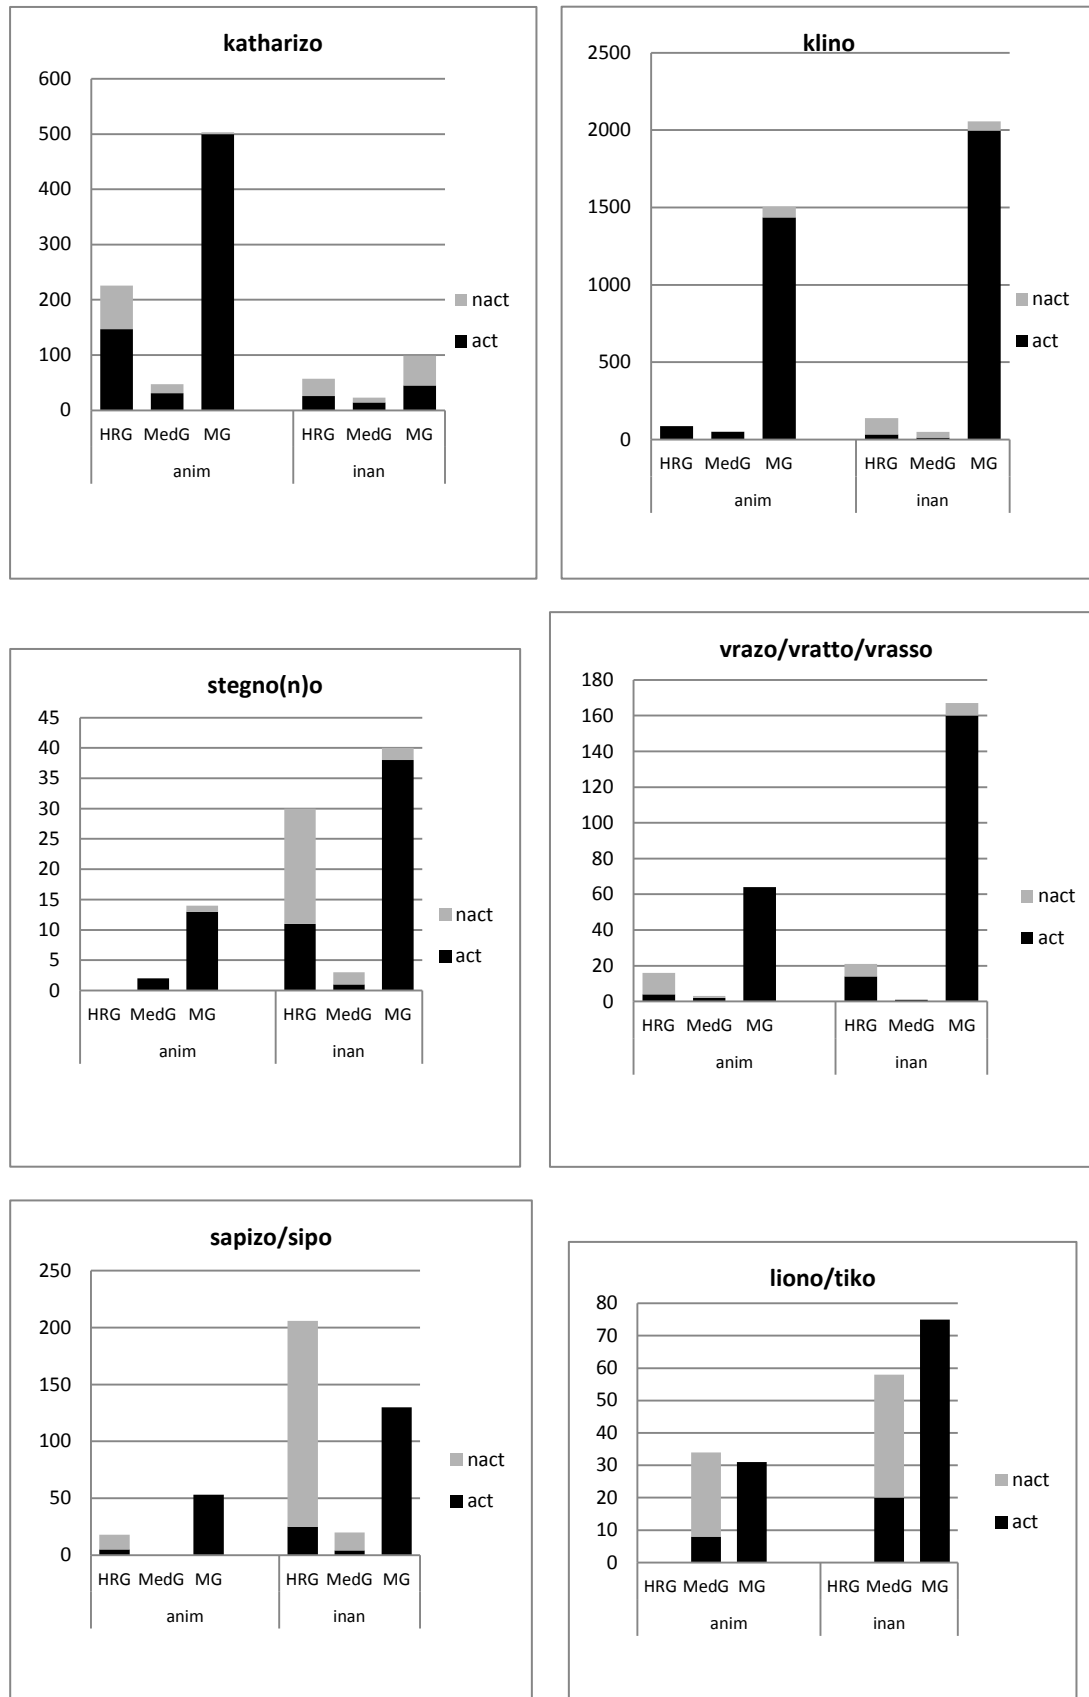

Graph 3 Distribution of the anticausative readings in ACT/NACT Voice morphology diachronically: analyses per verb

The anticausative readings reveal a similar pattern for all verbs examined except for *vrazo*, which is used both in ACT and NACT from the Hellenistic period (ACT:9 vs. NACT:9).⁷ The pattern outlined in the data is that there appears an overwhelming preference for NACT Voice marking in the pre-MG period, totally reversed in MG. More specifically, Pearson chi-square analyses show that from HRG to MedG there is a change (*katharizo*: $\chi^2=5.471$, $p=.019$, $\eta=.240$, Cramer's $V=.019$; *klino*: $\chi^2=4.005$, $p=.045$, $\eta=.215$, Cramer's $V=.045$; *stegno(n)o*: $\chi^2=1.037$, $p=.309$, $\eta=.222$, Cramer's $V=.309$; *vrazo*: $\chi^2=.286$, $p=.593$, $\eta=.117$, Cramer's $V=.593$; *sapizo*: $\chi^2=.838$, $p=.360$, $\eta=.061$, Cramer's $V=.360$; *liono*: $\chi^2=.972$, $p=.324$, $\eta=.050$, Cramer's $V=.324$) which becomes significant only from MedG to MG (*katharizo*: $\chi^2=32.615$, $p<.001$, $\eta=.833$, Cramer's $V<.001$; *klino*: $\chi^2=1.047E3$, $p<.001$, $\eta=.782$, Cramer's $V<.001$; *stegno(n)o*: $\chi^2=11.907$, $p=.001$, $\eta=.539$, Cramer's $V=.001$; *vrazo*: $\chi^2=64.330$, $p<.001$, $\eta=.574$, Cramer's $V<.001$; *sapizo*: $\chi^2=1.678E2$, $p<.001$, $\eta=.937$, Cramer's $V<.001$; *liono*: $\chi^2=1.313E2$, $p<.001$, $\eta=.958$, Cramer's $V<.001$).

One can reasonably wonder whether the change in Voice marking with anticausative structures is a side-effect of another change taking place at the same time. It is also worth looking at the above observation with respect to the distribution of Voice morphology overall per Verb (regardless of readings). In contrast to what we have seen (Graph 2) in relation to the variable frequency of ACT or NACT Voice morphology per verb, all verbs moved from NACT to ACT when used with an anticausative reading, and ACT is almost exclusively preferred with anticausative interpretation in MG.

We now turn to the examination of the distribution of subject animacy with ACT/NACT verb forms: a high frequency of animate subjects, regardless of Voice morphology, is considered evidence for a two-place predicate in terms of LCS (Levin 1993, Levin and Rappaport Hovav 1995, 2005). Even if causativization of a one-place predicate is involved, it is predicted to be less frequent than the basic LCS (intransitive structure).

Graph 4 Distribution of [+/- animacy] of syntactic subjects with (N)ACT verbs (all readings)

Graph 4 shows that the verb *katharizo* is used more frequently with an animate subject (+anim: 776 vs. -anim: 179), *klino* is frequent with an animate subject but preferred with an inanimate subject (+anim: 1644 vs. -anim: 2244) whereas this is not the case for the remaining verbs examined (*stegnono*, *vrazo*, *sapizo* and *liono*), which are more frequently used with an inanimate subject. We should further notice that *katharizo* with an inanimate subject is the only verb that appears as *ditipias*, i.e. the ACT and NACT forms are equally distributed in all three periods examined (ACT: HRG:26; MedG:14; MG:45 – NACT: HRG: 31; MedG:9; MG:54).

Furthermore, the data reveal that in MG, although equally frequently used with ACT and NACT morphology, *katharizo* with an animate subject is more frequent in ACT than NACT ($\chi^2=491.072$, $p<.001$). This preference for ACT vs. NACT, as already suggested, is not supported when an inanimate subject is present ($\chi^2=.818$, $p=.366$). *Klino* is used in ACT with animate subjects (HRG: 86 vs. 0; MedG: $\chi^2=35.852$, $p<.001$; MG: $\chi^2=1274.057$, $p<.001$) (favouring transitive readings –see below, Graph 5), a tendency that remained throughout the periods examined, while, in the presence of inanimate subjects, we observe a significant change: although in HRG and MedG, NACT morphology was preferred (HRG: $\chi^2=35.507$, $p<.001$; MedG: $\chi^2=10.796$, $p<.001$), in MG the verb is more frequently used in ACT ($\chi^2=1824.000$, $p<.001$). According to our data, *stegnono* was more frequently used in NACT with inanimate subjects, though not significantly so (HRG: $\chi^2=2.133$, $p=.144$; MedG: $\chi^2=.333$, $p=.564$), while it is preferred in ACT in MG ($\chi^2=32.400$, $p<.001$). However, the occurrences are very few throughout the periods examined. In the presence of an animate subject, the verb was (and is) very rarely used, almost exclusively with ACT (HRG: 0 (act) vs. 0 (nact); MedG: 2 (act) vs. 0 (nact); MG: 13 (act) vs. 1 (nact)). *Vrazo*, *sapizo* and *liono* present a similar pattern: in HRG and MedG the verbs were used both in ACT/NACT with animate subjects (although their diachronic frequencies differ) but are used only with ACT in MG (*vrazo*: 64; *sapizo*: 130; *liono*: 31). More specifically, *vrazo* was more frequent with NACT in HRG ($\chi^2=4.000$, $p=.046$) but very rare in MedG (2 (act) vs. 1(nact)), *sapizo* was more frequent with NACT in HRG ($\chi^2=118.136$, $p<.001$) but totally absent in MedG and *liono* was more frequent with NACT in MedG ($\chi^2=9.529$, $p=.002$). In the presence of inanimate subjects, the verbs present a different pattern: in HRG and MedG, *vrazo* was more frequent in ACT, but not significantly so ($\chi^2=2.333$, $p=.127$; only one occurrence in ACT found in MedG), while *sapizo* and *liono* in NACT ($\chi^2=118.136$, $p<.001$ and $\chi^2=7.200$, $p=.007$; found only in MedG: $\chi^2=5.586$, $p=.018$, respectively); in MG all of them are more frequently used in ACT (*vrazo*: $\chi^2=140.174$, *sapizo* (n=130) and *liono* (n=75) found only in ACT).

Graph 5 Distribution of anticausative vs. transitive uses with ACT verbs

Diachronically, if we compare (MedG vs. MG) the change of preference in anticausative vs. transitive use with ACT (Graph 5), we observe that this change has occurred from MedG to MG, since statistically significant differences are observed for (almost) all the verbs between these periods (*klino*: $\chi^2=39.399$, $p<.001$, $\eta=.107$, Cramer's $V<.001$; *stegnono*: $\chi^2=2.008$, $p=.156$, $\eta=.195$, Cramer's $V=.156$; *sapizo*: $\chi^2=23.558$, $p<.001$, $\eta=.360$, Cramer's $V<.001$; *liono*: $\chi^2=34.126$, $p<.001$, $\eta=.499$, Cramer's

$V < .001$); *vrazo* underwent this change earlier, from HRG to MedG, though statistically no significant differences are found, due to the small size of the data ($\chi^2 = .286$, $p = .593$, $\eta = .117$, Cramer's $V = .593$); *katharizo*, on the other hand, presents a similar pattern throughout the periods examined. Moreover, the differences between anticausative vs. transitive uses are statistically significant in most of the verbs: in HRG the transitive uses are more frequent with *klino* ($\chi^2 = 109.298$, $p < .001$), *stegnono* ($\chi^2 = 5.333$, $p = .02$) and *liono* ($\chi^2 = 134.552$, $p < .001$) while *katharizo* is exclusively transitive ($n = 173$); *vrazo* and *sapizo* show no statistical differences; in MedG transitive uses remain more frequent in *katharizo* ($\chi^2 = 33.800$, $p < .001$) *klino* ($\chi^2 = 40.323$, $p < .001$) and *liono* ($\chi^2 = 17.286$, $p < .001$), while no significant differences are found in *stegnono*, *vrazo* and *sapizo*. Finally, in MG the reverse pattern is attested: anticausative readings are significantly more frequent in *klino* ($\chi^2 = 40.323$, $p < .001$), *stegnono* ($\chi^2 = 9.680$, $p = .002$), *vrazo* ($\chi^2 = 108.586$, $p < .001$), *sapizo* ($\chi^2 = 158.562$, $p < .001$) and *liono* ($\chi^2 = 20.266$, $p < .001$), while transitive uses remain more frequent only with *katharizo* ($\chi^2 = 354.420$, $p < .001$).

In all, a between-verb analysis yields a significantly different pattern in the verbs *katharizo* and *klino* vs. all the others; *vrazo*, *sapizo* and *liono* show similar tendencies, while *stegnono* differs from *katharizo*, *klino* and *sapizo* but not from MG *liono*. In other words, *klino* and *katharizo* show stability with respect to the readings of ACT verb forms: they are dominantly used as transitives throughout the three periods examined. However, given that *klino* is a very frequent verb in MG, with many metaphorical uses, anticausative readings are also very frequent (antic vs. trans: $\chi^2 = .015$, $p = .904$). *Sapizo*, *liono* and *stegnono* were used transitively in HRG and MedG, while they receive more frequently an anticausative reading in MG. Finally, *vrazo* was equally used with transitive and anticausative readings in HRG, but it favours the anticausative reading since MedG.

Graph 6 Distribution of overt vs. null non-referential objects in transitive structures

With respect to the presence of an overt vs. a null (always, non-referential) object in the transitive uses we should notice that null non-referential objects are very rare in all the periods examined: they appear more frequently only with *sapizo* in HRG (overt: 12 vs. null: 6; $\chi^2 = 2.000$, $p = .157$) and they tend not to exist at all with all verbs but *vrazo* in MG (overt: 24 vs. null: 11; $\chi^2 = 4.829$, $p = .028$). Further statistical analyses are not, however, conducted due to the existence of very limited results in the majority of the verbs.

Overall, diachronically, the verbs examined show variation regardless of class in the distribution of Voice with all interpretations. Moreover, anticausative readings show a similar development of Voice marking (a shift from NACT to ACT) regardless of class. A relationship is also confirmed between subject animacy and transitive uses and LCS and between ACT with transitive or anticausative use and class LCS.

4. Conclusions

The question that arises is how to account for the instability and inconsistency in MG with regard to the first and the second class of anticausative verbs. The first proposal would be that the use of ACT only affected the anticausative reading of one-place predicates *at the LCS* initially (i.e. not *katharizo* ‘clean’ and *klino* ‘close’) and then spread to the other verbs. However, no LCS effect is found when looking at the anticausative reading diachronically. ACT appears to have spread to all verbs with a single argument at the syntactic level and probably on the basis of the (prototypical) use of ACT in unergatives (single argument verbs without argument movement). This implies a change in the properties of NACT morphology as such: NACT has changed from a marker with a double role, that is marking syntactic movement (internal Merge) of an internal argument to the subject position or of marking argument absorption (or blocking or suppression – according to the preferred analysis of detransitivisation) into a marker with a single role, that of argument absorption (subject is interpreted as object and another syntactic argument is absorbed/suppressed/blocked by the NACT morpheme). In MG, movement (internal Merge) is not marked through Voice morphology, while absorption is of a theta-role/argument in AG and of Case (structural) in MG. Accordingly, we would expect verbs of the second class (“ditipias” verbs), that are two-place predicates, to show NACT consistently (and not an ACT/NACT alternation). Most verbs of the second class have been introduced to the language much later (after HGR; *lerono* ‘get dirty’, *tsalakono* ‘crumble’: AD 12). It appears that two-place predicates could follow the ‘rule’ of one-place predicate when the syntactic derivation includes the internal argument only (Borer 2005). That means that ACT/NACT variation is not random: when the implicit argument is to be activated in the parse, then NACT is used, and NACT passives and NACT “anticausatives” share the same derivation. On the other hand, when the implicit argument needs not be activated, then ACT is used. On-going changes in the language show a convergence with verbs of the second class (class of verbs of two forms/“ditipias”) from the other two classes: verbs of the first class begin to be used with NACT Voice as well (*liono*), verbs of the third class begin to be used with ACT Voice as well (*eskise* besides *skistike* and *marane* besides *marathike*; examples 5a, 5b) (Fotiadou 2010, Roussou & Tsimpli 2007):

- (5) a. *I* *zaxari* *lionete* *ja* *na* *jini* *siropi*
 ART.NOM.SG sugar:NOM.SG melt:NACT.PRS.3SG for to become:3SG syrup:NOM
 ‘The sugar is melted to syrup.’
 b. *Ta* *maranes* *ta* *luludia*
 them:ACC.PL wilt:ACT.PST.PFV.2SG ART.ACC.PL flower:ACC.PL
 ‘You made the flowers wilt.’

Needless to say, we have to leave many questions open: for example, what caused the change in the properties of NACT. Possible directions to look for answers for this change are the replacement of structural and lexical case in earlier periods of Greek by structural case alone, or changes in the interaction between lexical and morphological aspect which might have affected the use and function of NACT Voice morphology.

PHONETIC VOWEL REDUCTION IN STANDARD MODERN GREEK

Angelos Lengeris

Aristotle University of Thessaloniki, Greece

lengeris@enl.auth.gr

ABSTRACT

This study examined phonetic vowel reduction in Standard Modern Greek by comparing the spectral and temporal characteristics of the five Greek vowels spoken by the same speakers in two speaking styles, namely conversational and read speech. Frequencies of the first two formants (F1 and F2) and duration were measured and the Euclidean distance from the centroid of the vowel space was computed for each vowel. Results showed extensive vowel reduction and variability in conversational speech compared to read speech. Across speaking styles, unstressed vowels were shorter and closer to the centre of the vowel space than stressed ones.

Keywords: Greek, phonetic vowel reduction, conversational speech

1. Introduction

Phonetic vowel reduction is a process whereby an intended vowel target is not reached. Reduced vowels are shorter and occupy a more central position in the vowel space compared to non-reduced ones. This gradient subphonemic process, often referred to as vowel undershoot, should not be confused with phonological vowel reduction, an obligatory, categorical substitution of sounds whereby vowel quality distinctions are neutralized in unstressed syllables (e.g. English *photographic* /fəʊtə'græfɪk/ vs. *photography* /fə'tɒgrəfi/). This study provides an in depth examination of phonetic vowel reduction in Greek by investigating the effect of speaking style and stress on the spectral and temporal characteristics of Greek vowels.

Factors that have been found to contribute to phonetic vowel reduction include *rate of speech* (Lindblom, 1963), *stress* (Delattre, 1969), *context* (Lindblom, 1963; Moon & Lindblom, 1994) and *speaking style* (Koopmans-Van Beinum, 1980; Moon & Lindblom, 1994). According to the Hyper-Hypo (H&H) theory (Lindblom, 1990), speech communication involves a balance between the speaker's attempt to minimize articulatory effort (i.e., speaker constraints) and the listener's need to understand what is said (listener constraints); depending on the communicative situation, speech production thus exhibits a wide range of variation along a continuum of hypo- (reduced) to hyper- (non-reduced) speech. Speakers are free to hypo-articulate in ideal listening conditions (e.g. quiet environments) but tend to hyper-articulate in adverse listening conditions (e.g. background noise) or when they think the listener might have difficulty understanding their speech (e.g. when addressing a person with a hearing loss, a child or a non-native speaker).

Despite acknowledging style-induced modifications in the speech signal, most research on vowels has examined CVC syllables, word lists, or short utterances that are read aloud under well-controlled conditions ('laboratory speech'). This choice is motivated by the fact that the use of laboratory speech allows designing and conducting controlled experiments. However, since laboratory speech differs in a highly systematic way from the type of speech speakers use in their everyday life, it remains questionable whether laboratory speech findings can generalize to conversational, spontaneous speech.

Relatively few studies have examined phonetic vowel reduction in conversational speech (Koopmans-Van Beinum, 1980 for Dutch; Deterding, 1997 for English; Harmegnies & Poch-Olivé, 1992 for Spanish), demonstrating shorter vowel durations and 'shrinkage' of the vowel space in conversational speech compared to read speech. Limited research is also available on the acoustic characteristics of Greek vowels. According to Dauer (1980), only high vowels reduce in Greek while unstressed vowels do not change in quality. However, this finding is not confirmed by more recent studies that have begun to explore phonetic vowel reduction in Greek (Baltazani 2006, 2007; Fourakis

et al., 1999) using read speech materials. These studies show an overall reduction of the vowel space in Greek unstressed syllables compared to stressed ones. Nicolaidis (2003) was the first to examine the acoustic characteristics of Greek vowels in spontaneous speech using monologues produced by two Greek male speakers. Her results show extensive variability and overlapping formant distributions especially in the centre of vowel space, resulting in less distinct vowels than previously reported in the Greek literature. The current study extends Nicolaidis' (2003) study in two ways: first, by examining a larger number of speakers and consequently a larger number of vowel tokens and, second, by comparing the spectral and temporal characteristics of Greek vowels in two speaking styles, namely conversational and read speech. The conversational speech materials were drawn from recordings of natural conversations between each participant and the author. Read versions of these conversations were recorded from the same speakers one week after the first recording. That way, identical materials in two speaking styles were elicited, spoken by the same speakers under the same recording conditions. The main goal of this study is therefore to examine the extent of phonetic vowel reduction in Greek, a language with a simple 5-vowel system which does not employ phonological vowel reduction.

2. Method

2.1 Participants

Eight native speakers of Standard Modern Greek, all post-graduate students at University College London, with a mean age of 24 years (range = 22-27 years) participated in the study. Participants reported no speech, language or hearing disorders and none had spent a period of more than one year in the UK at the time of the recordings. In order to avoid extensive variability due to anatomical differences between male and female speakers, only male speakers were recruited.

2.2 Recordings

Speech recordings took place in an anechoic chamber at the University College London with a sampling rate of 44.1 kHz, using a Sony 60ES DAT recorder with a B&K Sound Level Meter Type 2231 fitted with a 4165 microphone cartridge, placed at a distance of 50 cm from the speaker's mouth.

As already mentioned, conversational speech materials were drawn from recordings of natural conversations (semi-directed interviews) between each participant and the author. Each conversation lasted approximately ten minutes. The author chatted with each participant prior to the recording to make him feel relaxed. The conversations revolved around participants' hobbies, studies, etc. Based on speech naturalness and fluency, approximately five minutes were selected from each speaker to be further analyzed.

Conversations were transcribed orthographically by the author after removing repetitions and pauses and the orthographic versions were recorded from the same speakers one week after the first recording. Participants were instructed to read the paragraphs at a comfortable speaking rate as if they were asked to read aloud a passage in the classroom. They were also instructed to read the sentence again if they made a mistake when reading the materials. As a result, identical materials in two speaking styles were recorded by each participant. There was no way to perfectly control for prosodic context since it is impossible for speakers to reproduce the same intonation patterns.

Data were analyzed using the SFS speech analysis software (Huckvale, 2008). Vowels preceded or followed by other vowels were excluded from the analysis. Segmentation was made manually, taking the waveform and the wide-band spectrogram into consideration; each vowel was defined by the beginning and the end of its formant structure. Acoustic measurements of duration and first (F1) and second (F2) formant frequencies were made automatically using SFS scripts, then checked manually and corrected. In case of missing vowels in one speaking style (most commonly in conversational speech), the corresponding vowel in the other style was excluded from the analysis. For purposes of data presentation and statistical analyses, values in Hertz were converted to the auditory Bark scale. The formula proposed by Traunmüller (1990) and given in (1) was used, where Z is frequency in Bark and f is frequency in Hertz:

$$(1) \quad Z = \left[\frac{26.81f}{(1960 + f)} \right] - 0.53$$

Figure 1 Mean duration (ms) of Greek vowels in read speech (left) and conversational speech (right) in both stress conditions

3. Results

3.1 Effects of speaking style and stress on vowel duration

Figure 1 shows the mean duration of each Greek vowel in read and conversational speech in both stress conditions. As can be seen, Greek vowels were shorter in conversational than in read speech. In addition, across speaking styles, unstressed vowels were shorter than stressed ones. Vowel durations were submitted to a three-way analysis of variance (ANOVA) with Speaking style (read, conversational), Stress (stressed, unstressed) and Vowel (5 levels) as factors. There was a significant main effect of Speaking style [$F(1,3460) = 58.253, p < 0.001$], confirming that Greek vowels were shorter in conversational speech than in read speech and a significant effect of stress [$F(1,3460) = 156.046, p < 0.001$] confirming that unstressed vowels were shorter than stressed ones. There was also a significant main effect of Vowel [$F(4,3460) = 26.946, p < 0.001$]. Pairwise comparisons (Bonferroni adjusted) showed that, across speaking styles and stress conditions, the low central vowel /a/ was produced with the longest duration, the high vowels /i/ and /u/ with the shortest durations and the mid vowels /e/ and /o/ were in between. Similar results are reported in the literature for Greek vowels (e.g. Baltazani, 2006; Fourakis et al. 1999; Nicolaidis, 2003) and other languages (for a review, see Lehiste, 1970). There was also a significant Speaking style \times Stress interaction [$F(1,3460) = 22.54, p < 0.001$], indicating that vowels in read speech were shortened to a larger degree when unstressed than vowels in conversational speech (25% vs. 15% respectively). Finally, a significant Vowel \times Stress interaction [$F(4,3460) = 7.54, p < 0.01$] indicated that not all vowels were shortened to the same degree when unstressed; /a/ was shortened to a larger degree than the mid vowels /e/ and /o/ and the high vowels /i/ and /u/. Mean durations and standard deviations for the five Greek vowels in two speaking styles in both stress conditions are given in Table 1. Focusing on conversational speech materials, vowel durations were found to be somewhat shorter than those reported in Nicolaidis (2003) who provides the following duration values (pooled over stressed and unstressed conditions) for vowels in spontaneous speech): /i/ = 69.1 ms, /e/ = 80.9 ms, /a/ = 85.4 ms, /o/ = 78.4 ms and /u/ = 59.8 ms. One possible explanation is that speech in conversation examined in the current study is less careful and hence faster than speech in monologues examined in Nicolaidis' (2003) study.

Vowel	Read speech		Conversational speech	
	Stressed	Unstressed	Stressed	Unstressed
/i/	71.34 (23.77)	51.83 (17.86)	54.74 (22.76)	50.14 (23.64)
/e/	85.98 (27.48)	61.43 (23.63)	70.53 (22.51)	55.21 (21.64)
/a/	92.94 (29.25)	69.76 (22.63)	76.32 (25.62)	60.32 (19.33)
/o/	78.44 (20.54)	65.16 (18.42)	61.26 (19.24)	55.31 (17.89)
/u/	76.18 (22.94)	55.11 (13.55)	60.09 (10.43)	52.02 (16.65)

Figure 2 Mean F1 and F2 frequencies (Bark) of Greek vowels spoken in read speech in stressed (black squares) and unstressed position (grey diamonds)

Figure 3 Mean F1 and F2 frequencies (Bark) of Greek vowels spoken in conversational speech in stressed (black squares) and unstressed position (grey diamonds)

3.2 Effects of speaking style and stress on formant frequencies

Mean F1 and F2 frequencies (converted to the Bark scale) of the five Greek vowels in read and conversational speech are plotted in the vowel space in Figures 2 and 3 respectively and are also given in Hz (standard deviations in parentheses) in Table 2. A visual inspection of Figures 2 and 3 reveals that Greek vowels in conversational speech show a tendency towards reduced vowel spaces (i.e., they occupy less peripheral positions) when compared to vowels in read speech. Moreover, across speaking styles, unstressed Greek vowels are reduced towards the centre of the vowel space compared to stressed ones. These results agree with Koopmans-Van Beinum (1980), Deterding (1997) and Harmegnies & Poch-Olivé (1992) who compared vowels in conversational and read speech. The results are also in agreement with Fourakis et al. (1999) and Baltazani (2006, 2007) who found a reduction of the Greek vowel space in unstressed position using read speech materials.

Vowel	Read speech				Conversational speech			
	Stressed		Unstressed		Stressed		Unstressed	
	F1	F2	F1	F2	F1	F2	F1	F2
/i/	385 (71)	1995 (86)	376 (82)	1918 (102)	385 (80)	1895 (97)	376 (86)	1872 (104)
/e/	522 (74)	1742 (82)	489 (96)	1715 (86)	492 (87)	1690 (91)	470 (89)	1643 (95)
/a/	644 (84)	1421 (81)	628 (104)	1450 (90)	609 (93)	1444 (92)	592 (109)	1432 (93)
/o/	502 (86)	1165 (103)	500 (101)	1190 (102)	470 (95)	1179 (112)	471 (102)	1208 (117)
/u/	362 (74)	1102 (118)	372 (83)	1126 (116)	376 (76)	1200 (124)	403 (114)	1206 (119)

Table 2 F1 and F2 frequencies in Hz (standard deviations in parentheses) of Greek vowels in read and conversational speech in both stress conditions

To test these observations statistically, the Euclidean distance for each vowel token was calculated from the *centroid*¹ of each speaker's vowel space. The formula given in (2) was used, where $\overline{F1}$ is the mean of each speaker's F1 values and $\overline{F2}$ is the mean of each speaker's F2 values. The smaller the Euclidean distance, the more centralized a vowel token is.

$$(2) \quad ed = \sqrt{(F1 - \overline{F1})^2 + (F2 - \overline{F2})^2}$$

Table 3 displays the mean Euclidean distance of the five Greek vowels in read and conversational speech in both stress conditions. Euclidean distances were submitted to a three-way ANOVA with Speaking style (read, conversational), Stress (stressed, unstressed) and Vowel (5 levels) as factors. The ANOVA yielded three main effects: of Speaking style [$F(1,3460) = 19.543, p < 0.001$] with vowels in conversational speech being closer to the centroid, of Stress [$F(1,3460) = 9.434, p < 0.01$] with unstressed vowels being closer to the centroid and of Vowel [$F(4,3460) = 322.545, p < 0.001$]. These results confirmed a reduction of the vowel space not only in terms of quantity as shown in section 3.1 but also in terms of quality when moving from (a) conversational to read speech and (b) stressed to unstressed position.

A final point of interest concerns a comparison of variability in F1 and F2 frequencies in conversational and read speech. As can be seen in Table 2, standard deviations of F1 and F2 were consistently larger in conversational speech compared to read speech which, combined with the centralization of F1 and F2 values found in the data, results in less differentiated vowels in conversational speech than in read speech (see Nicolaidis, 2003 for a similar finding concerning Greek vowels in spontaneous speech).

¹ The *centroid* of the vowel space is the grand mean of all formant measurements taken for each speaker.

Vowel	Read speech		Conversational speech	
	Stressed	Unstressed	Stressed	Unstressed
/i/	2.13 (0.53)	2.04 (0.61)	1.91 (0.57)	1.90 (0.61)
/e/	1.09 (0.51)	1.06 (0.57)	1.05 (0.52)	0.97 (0.57)
/a/	1.34 (0.52)	1.23 (0.60)	1.22 (0.58)	1.19 (0.60)
/o/	1.81 (0.73)	1.73 (0.71)	1.82 (0.78)	1.73 (0.79)
/u/	2.62 (1.05)	2.35 (0.85)	2.24 (0.98)	2.10 (0.89)

Table 3 Euclidean distance (Bark) for Greek vowels in read and conversational speech in both stress conditions (standard deviations in parentheses)

4. Discussion

This study examined the spectral and temporal characteristics of Greek vowels in two speaking styles in stressed and unstressed position with the aims of (a) adding to our existing knowledge on the acoustic characteristics of Greek vowels and (b) revealing style-induced differences. The styles under investigation were conversational and read speech (the read version of conversational speech materials). If we consider speaking style as a continuum where conversational speech stands at one end of the continuum and isolated syllables (or words) at the other, the speaking styles to be compared are relatively close to each other. Nonetheless, it was hypothesized that significant differences between these speaking styles in terms of duration, formant frequencies and Euclidean distance of the centroid of the vowel space would be found.

As far as duration is concerned, vowels in conversational speech were significantly shorter compared to vowels in read speech in both stress conditions. In addition, stressed vowels were longer than unstressed ones across speaking styles. Finally, the results confirmed the well-documented phenomenon of low vowels being inherently longer than high vowels (e.g. Lehiste, 1970); across speaking styles and stress conditions, the open central vowel /a/ was found to be the longest vowel, followed by the mid vowels /e/ and /o/, which were in turn followed by the high vowels /i/ and /u/.

In order to test whether vowel space reduced in conversational speech, the Euclidean distance for each vowel token was calculated from the centroid of the vowel space. Vowels in conversational speech were found to occupy a more central position in the vowel space than vowels in read speech with unstressed vowels being closer to the centroid in both speaking styles (Koopmans-Van Beinum, 1980; Deterding, 1997; Harmegnies & Poch-Olivé, 1992). These findings are in agreement with the target-undershoot model (Lindblom, 1963; Moon & Lindblom, 1994) and the H&H theory (Lindblom, 1990). Within this framework, speech production depends on the communicative situation and can vary along a hyper- to hypo- continuum. As previously mentioned, the conversational speech materials for this study were elicited in a sound isolated chamber that ensured ideal speaking and listening conditions. The conversation between the participants and the author was fairly friendly and informal. In this experimental setting, speakers are expected to produce reduced speech in order to economize articulatory effort. The read speech materials for the study were elicited under the same recording conditions. However, the participants read a passage instead of conversing freely and were instructed to read the way they would read aloud a passage in the classroom if the teacher asked them to. In this experimental setting, conversely, speakers are expected to produce less reduced vowels, closer in acoustic quality and quantity to the target values. It is important to mention that vowels in read speech in this study were found to be less peripheral when compared to formant values given for Greek vowels spoken in isolated sentences (e.g. Baltazani, 2006; Fourakis et al., 1999), indicating that these vowels were reduced too but to a lesser degree than vowels in conversational speech. Future research could compare vowels in three speaking styles, namely conversational speech, continuous read speech and words isolated or embedded in a carrier sentence. It would also be interesting to test Greek native speakers' perception (e.g. vowel identification and goodness ratings) of Greek vowels spoken in conversational speech when context (i.e., lexical information) is removed.

In summary, the results of this study provide strong evidence for the existence of phonetic vowel reduction in Greek and demonstrate two ways in which vowels in conversational speech differ from vowels in read speech; conversational speech vowels are shorter in duration and less peripheral in the $F1 \times F2$ vowel space. These findings add to the existing evidence in the literature that read speech (used commonly in speech production experiments) differs in a highly systematic way from the type of speech used in our everyday communication.

Acknowledgments

I would like to thank an anonymous reviewer for valuable comments on an earlier version of the manuscript.

MODAL AND FUTURE PERIPHRASES WITH *EIMAI* IN THE HISTORY OF GREEK AND ITS DIALECTS

ΠΕΡΙΛΗΨΗ

Είναι γνωστό διαγλωσσικά ότι περιφραστικές ρηματικές δομές που σχηματίζονται με τη χρήση ενός βοηθητικού ρήματος με την αρχική σημασία ‘είμαι’ ή ‘γίνομαι’ όχι μόνο εκφράζουν συχνά δεοντική ή επισημική τροπικότητα αλλά και αποκτούν κάποτε (εξειδικευμένες ή μη) μελλοντικές χρήσεις. Με αφετηρία τη διαπίστωση ότι η κοινή νεοελληνική αλλά και πολλές, ιδίως ανατολικές, νεοελληνικές διάλεκτοι διαθέτουν τέτοιες δομές επιχειρείται εδώ η ανίχνευση της παρουσίας και η περιγραφή της σημασιολογικής διαδρομής και γραμματικοποίησής τους σε προγενέστερες φάσεις της ελληνικής με έμφαση στην ύστερη μεσαιωνική περίοδο.

Keywords: copula, obligation, ability, possibility, predestination, scheduled / expected future

1. Introduction: *είμαι* as modal/future marker

Many languages possess structures expressing modality of obligation that are formed with the auxiliary verbs ‘be’ or ‘become’ or with affixes that are derived from these verbs (For a catalogue of such languages, see Bybee, Perkins and Pagliuca, 1994:182-3). For example, both Greek and English have modal periphrases expressing obligation with *be to* and *είμαι να* respectively:

- (1) - *I am to go* to the doctor
- *Είναι να πάω* στο γιατρό

The common semantic basis of the two structures is that “the agent has been set or scheduled to do something by outside forces” and for this reason is obliged to act. The difference between these structures and the equivalent but more frequent deontic constructions with *have to* and *έχω να* is that the latter express a more general sense of obligation, not limited to situations where something has been planned or arranged. In addition, in the cases of *be to* and *είμαι να*, the obligation of the agent is more relaxed or remains open (Bybee, Perkins and Pagliuca, 1994: 184).

How does it happen that the meaning of obligation comes to be expressed by a structure based on a verb whose prototypical meaning involves existence, being, situation? According to the three authors (184), the sense of obligation also comes partly from the infinitival complement; more analytically, the structure with the copula ‘to be’ shows that the agent is linked to an action, the time reference of which may be either past, present or future. Thus the action may be either complete, in which case it may be expressed with a past participle, e.g. *είμαι γραμμένος* / *I am written*, current, in which case it is often expressed by a present participle or a gerund, e.g. *είμαι γράφων* / *I am writing*, or projected, in which case it may be realized with an infinitive, e.g. **είμαι γράφειν* / *I am to write*. The application of this typological schema in Greek means of course that the linking of the agent with a future action also involves a complement clause – expressing purpose or volition – as a syntactic equivalent to the infinitive, e.g. *είμαι (για) να γράφω* (see also footnote 1). In almost all the above examples, *είμαι/be* can be replaced by the possessive auxiliary *έχω/have*. The fact that these are interchangeable is a syntactic indication that ‘be’ can acquire a suggestion of possession. This may also be observed in various other syntactic environments (e.g. with spatial markers, possessive modifiers etc.): if an object ‘is to me’ (also on me, near me, of John, of Mary etc.), then it ‘belongs to me’ (to John, to Mary etc.). And of course there is a close relationship between possession and obligation; if an action belongs to me, I am

under obligation to bring it to completion (For the stages between possession and obligation, see Heine, 1993:42; for obligation in Greek, see Newton and Veloudis, 1980).

Closely linked with the idea of obligation are the concepts of being expected, scheduled or predestined to take place. Crosslinguistically, these meanings too may sometimes be expressed by structures with ‘to be’. Less commonly, ‘to be’ may be used in similar structures that express the modality of ability (For a catalogue of languages which express the abovementioned modalities using the verb ‘to be’, and for a theoretical discussion of the subject, see Bybee, Perkins and Pagliuca, 1994: 186-7 and 249-51).

It is known that future tenses very often develop from structures expressing modalities of obligation or pre-arranging (Bybee, Perkins and Pagliuca, 1994: 258-64), given that both strongly imply the speaker’s intention to carry out an action, and by extension a prediction concerning the realization of this action. Similarly, modality of ability can develop into root possibility, then subsequently intention, and ultimately future (265-6). Thus it is not surprising that typologically the verb ‘to be’ is a common source of future tenses (253).¹

Greek is among the languages that make use of this crosslinguistically widespread means for expressing a fairly broad range of modalities (obligation, predestination, ability, root possibility, epistemic possibility, intention etc.), including future tense. All the above observations underline the high degree of syntactic and semantic flexibility possessed by this verb, and justify its characterization as a highly generalized marker for the expression of modal and temporal distinctions.

2. Corpus - method - aim

Starting from the obvious fact that Modern Greek, both in its standard and (much more so) dialect forms, possesses such verbal constructions with *είμαι*, this paper focuses on earlier stages of the history of the Greek language, from the Classical and Hellenistic periods to approximately 1500 AD or a little later, with particular emphasis on the vernacular literary texts of late medieval period. The sheer amount of material available has consequences both for the method that I follow here, basically qualitative, and for the aim of this paper: I attempt, within the framework of grammaticalization theory, to formulate working hypotheses concerning the origin, function and development of the modal structures with the present tense of the copula *είμαι* that we find in Greek.

3. Analysis of the material

3.1 Classical Greek

The best-known use of *είμαι* in a modal periphrasis in Ancient Greek is found in the already impersonal structure *ἔστι* + infinitive. Indeed, this structure seems to cover a large part of the range of modalities that corresponds to Modern Greek *μπορεί*:

(2) εἴ τις [...] εἶχε [...] οὐλὰς ἐν τῷ σώματι [...] ζῶν, καὶ τεθνεῶτος τὸ σῶμα ἔστιν ἰδεῖν ταῦτα ἔχον

If someone had scars on his body while yet alive, you can see that his body still has them after his death.²

(*Gorgias* (Plato), 524c; 4th c. BC)

In example (2), the original modality of ability gives rise to a meaning of root possibility: the agent is able, and external conditions do permit it. The same stage, or perhaps a step further in the direction of epistemic possibility, appears to be represented in the following example; the general conditions are fulfilled, or the situation described in the proposition may represent the truth:

¹ See also the following predicates which lead together with *είμαι* to the future projection of an action: a) result clauses, in the construction *είμαι ὥστε* (see below, example 4 and footnote 3), b) prepositional phrases, in the constructions *είμαι πρὸς* (*γὰρ*, *σε* etc.) + noun (These structures appear in the Hellenistic and subsequent periods, e.g. [ἦν]ωχλήθην ἰσχυρῶς, νυνὶ δὲ πρὸς τῷ ἀναλαμβάνειν εἰμί ‘I fell gravely ill, but now I am nearing recovery’ (*p.zen.pestm.51* (3); 257 BC), *εἶναι πρὸς σωτηρίαν* ‘he is going to be saved’ (*Spaneas*, O 207) etc.), c) genitive articular infinitives, in the construction **είμαι τὸν γράφειν* (see below example 5).

² The translations are mine (except where indicated otherwise), and are as faithful as possible to the original.

(3) τοιάδε μέντοι τῶν φρενοπλήκτων βουλευμάτων ἔπη τ' ἔστιν ἀκοῦσαι
You may hear such words and thoughts from furious people.

(*Prometheus Bound* (Aeschylus), 1054-5; 5th c. BC)

The frequentative meaning implicit in utterance (3) ('Every time that anyone is furious, they think and speak like that.') highlights the shift of the modal verb towards epistemic modality (see Traugott 1989:43, and especially Βελοῦδης 2010:59, where reference is made to the close relationship between weak epistemic modals, frequentative meaning, and prophetic future).

Two points about the modality of *ἔστι* in Ancient Greek must be borne in mind here. The first is that in precisely these constructions, the accent of the auxiliary moves obligatorily to the penultimate syllable, which is an indication not only that it is increasingly syntactically bound to the following infinitive, but also that it is behaving as a clitic. That these structures are in the early stages of grammaticalization can also be seen from the analogous accent shift observed in periphrastic quantifiers with the 3rd person singular of the auxiliary, e.g. *ἔστιν ὅς* 'someone', *ἔστιν ὅπου* 'somewhere', *ἔστιν ὅτε* 'sometimes' etc., or after some grammatical words (such as *οὐκ*, *καί*, *ἀλλά* etc., e.g. *οὐκ ἔστι* 'it is not', cf. *τοῦτο ἐστί > τοῦτ' ἔστι* 'in other words' etc.). The second point is semantically and syntactically important. I quote the next distich from Sophocles's *Philoctetes* (5th c. BC) together with its English translation (Jebb, 1898:656-7):

(4) ἄρ' ἔστιν ὥστε κἀγγύθεν θεῶν λαβεῖν καὶ βαστάσαι με προσκύσαι θ' ὥσπερ θεόν;

Is there any way that I might have a closer view of it – and handle it, and salute it as divine?

Here Neoptolemos is not wondering about his ability to see or his chances of seeing the bow of Philoctetes, but whether it is allowed, whether he has permission to see it – permission which is given immediately afterwards. Bybee, Perkins and Pagliuca (1994:199) note that the modality of permission is a branch of root possibility. From a syntactic point of view, what is different here is that the auxiliary is combined with a result clause, or rather with the result marker *ὥστε* which is prepositioned before the infinitival complement.³

3.2 Hellenistic Koine and early medieval Greek

A third syntactic possibility, already available in the Hellenistic period, is exemplified by the following example from the Septuagint (3rd-2nd c. BC):

(5) καὶ εἶπεν· ἐὰν κραταιωθῇ Συρία ὑπὲρ ἐμέ, καὶ ἔσεσθέ μοι εἰς σωτηρίαν, καὶ ἐὰν κραταιωθῶσιν υἱοὶ Ἀμμὼν ὑπὲρ σέ, καὶ ἐσόμεθα τοῦ σῶσαί σε

And he said: if Syria becomes stronger than me, then you will (be about to) save me, and if the sons of Ammon become stronger than you, then we will (be about to) save you

(2 Samuel 10.11)

From a morphosyntactic point of view, what is important about the structure *ἐσόμεθα τοῦ σῶσαί σε* (literally: 'we will be of to save you') is that 'be' remains inflected, while the complement has the genitive of purpose of the articular infinitive (see also the parallel expression *ἔσεσθέ μοι εἰς σωτηρίαν* in the preceding line, where in place of the articular infinitive we have as a complement a prepositional phrase showing purpose, too). From the point of view of semantics, it seems that this structure is just a step away from the immediate or expected future. In LSJ this example is included in the entry *εἰμί* for the meaning 'to be about to' (C.2.f), while in the Latin and English translations in the Digital Library of Perseus, the periphrasis is rendered by the futures 'auxiliabor tibi' and 'we will come and help you' respectively. Notwithstanding the fact that the future reading of this structure may be affected by the presence of the synthetic future *ἐσόμεθα*, it is more likely that the structure in question actually conveys the readiness/imminence of the subject to act. Whatever the case, we are dealing with an agreement by the terms of which mutual help is expected or prearranged for the near future in the face of an external threat (for the terms 'immediate' and 'expected/scheduled' and the close relationship between them, as well as with the simple future, see Bybee, Perkins & Pagliuca, 1994:244-7, 249-51).

³ It is not by chance that, as Jebb (1932) observes in his comments on this verse, similar result structures are found with other premodal verbs such as *θέλω* or *δυνατόν (ἐστί)*, e.g. *ἀδύνατον ὑμῖν ὥστε Πρωταγόρου τοῦδε σοφώτερόν τινα ἐλέσθαι* (*Protagoras* (Plato), 338) 'It is impossible for you to choose...'.

A new development in this period is the identification of 3sg. *ἔνι* (alternative form of 3sg. *ἔνεστι*, from the prefixed verb *ἔνειμι* ‘to be in’) with *ἐστί*, resulting in their parallel use (Mandilaras, 1973:77). The two types also coincide in their impersonal uses with the general meaning of ability / root possibility, although the structures with *ἔνι* are rare and relatively late-attested (there are only three examples, all in private papyri from the end of the Hellenistic and beginning of the early Medieval periods):

- (6) ἐπι δὲ οὐκ ἔνι ἀπελθῆν ᾧ τοις τέσ\σαιρες/

Because I can’t (it is impossible for me to) leave with four animals. (?)

(sb.18.13598 (9); 6th–7th c. AD)

See also *bgu.4.1024* (5, 20-1); 360 AD and *p.cair.masp.2.67199*; 520–530 AD. In contrast, the impersonal structures with *ἔστι* are much more common and occur regularly throughout the period in question, e.g. *χιτωνάριον δὲ τῷ παιδαρίῳ οὐκ ἔστιν εὔρεῖν* ‘I can’t find a little tunic for our little child’ (*p.cair.zen.4.59644* (12), mid-3rd c. BC; see also *psi.4.297*; 5th c. AD etc.).⁴

In the material from the papyri I also found an example of the periphrasis *ἦν* (= *ἦ*; subjunctive) + infinitive in an embedded purpose clause with *ἵνα*:

- (11) καὶ οὕτως ὄρμασα<ι> τῷ σὲν ζυγὴν μαχαίρην καλὸν καὶ πρόσοψιν λέων ἔχοντα ἵνα ἦν
εὐζηλότερον γενέσθαι καὶ θαυμάζομεν (leg. θαυμάζωμεν)

And so I decorated your good penknife with a lion’s face, so that it can (in order to) be more enviable and we (can) admire it.

(o.claud.2.279 (5-9); 2nd c. AD)

The important thing here is that, functionally, the structure seems to have been generalized: it is nothing more than a subjunctive / subordination marker (*ἦν γενέσθαι* = *γέννηται*), presumably as a consequence of the falling together of the two forms of the auxiliary (*ἦ* / *ἦν*). The same conclusion is reached by Markopoulos (2009:149-55) regarding the structure *να ἔχω* + infinitive which appears in late Byzantine texts.

3.3 Late Medieval Greek and Modern Greek Dialects

Almost the same syntactic pattern seen in example (5), differing only in that the infinitive (but not its article) has been replaced by a *να*-clause, appears more than a thousand years later in the *Ermoniakos* (14th century). The relatively conservative character of the language of this text is what makes possible a comparison with the equivalent Hellenistic structure. On the level of form, *εἶναι* now appears in place of *ἐστί* (for the development of the morphology of *εἶμι*, see Καψωμένος 1953). At the point which interests us, a disheartened Patroklos conveys to Achilles the wretched image of the battle with the Trojans and, having referred to a long list of dead and wounded, emphasizes the fact of the imminent death of two more heroes:

- (12) ο δε Σίσυφος και Νέστωρ συν γαρ τῷ Λοκρῷ τῷ Αἴᾳ εἶναι γουν του ν’ ἀπεθάνουν [...] και
προς κίνδυνον οι πάντες εἶναι γαρ του να γενώσιν

Sisyphus and Nestor, together with the Locrian Ajax, are about to die, and everyone is about to find themselves in danger.

(*Ermoniakos*, P 245-56)

It is obvious that the two structures with *εἶναι του να* + subjunctive have the meaning of immediate / expected future, although from these particular examples it is not possible to confirm the impersonal syntax of the auxiliary. In the same text we also find two archaic structures of the type *εἶναι* + infinitive; this time the old modality of ability / possibility has been replaced by a meaning of preordained or predestined future similar to that expressed by the Modern Greek structure *μου (σου, του etc.) μέλλει να*:

⁴ For more examples, including one with the future *ἔσται* and two with the optative *εἴη*, see Mayser 1906 (II, 1: 165, 307, 339).

- (13) και το κυρωθέν καθάπαξ ου γαρ είν' αναλυθήναι
And that which has been sealed (by fate) now and forever is not destined to be erased
(B 88-91)

(See also *Ψ* 287, where we find the same structure with the same modality). Ambiguity between possibility and preordained future is found in the works of Sachlikis (14th c.), the earliest representative of Cretan literature (Vitti, 1960):

- (14) μη λυπηθής την πολιτικήν εις όσα και αν κλάψη
ότι ποτέ το κλάμα της δεν είναι να την βλάβη
Don't pity a prostitute, however much she cries
because her tears can never (are never going to) do her any harm
(367-8)

Here the periphrasis with *είναι*, which now takes a subordinate clause (*να* + subjunctive) as a complement, expresses the fact that not only it is impossible for tears to harm the prostitute, but also that this is not destined to happen, which is emphasized by the use of the temporal adverb *ποτέ* (see also *καθάπαξ* in the previous example).

The meaning of imminent / near or preordained / predestined future can be clearly discerned in another poem by Sachlikis, as well as in a number of 14th-15th century sources of Cretan, Cypriot and more generally south-eastern origin, especially when the situation described involves concepts such as fate, death, illness etc. (see also examples 12 and 13): *κι όταν παγαίνουν κι έρχονται και ρωτούν πώς ιστέκει, λέγουν το δια να μάθουσιν αν ένι ν' αποθάνη* 'And when they come and go and ask how he is, they say it to find out whether he is going to die' (*Sachlikis* (Wagner, 1874), 129-30; Crete), *από της πείνας της πολλής όλοι <εί>ναι ν' αποθάνουν* 'Because of the great hunger everyone is going to die' (*Diegesis Apolloniou*, 118; maybe from Cyprus), *λοιπόν, παιδί μου, σαν θωρώ, δεν είναι πλια να φθάσω* 'so, my child, as I see it I am not going to live anymore' (*Rimada Apolloniou*, A 1789; see also A 1784-5, A 407-8), *και λαλούν τον: «είναι να γίνει μέγαν σκάνταλον»* 'And they say to him: "there's going to be a big scandal"' (*Boustronios*, A 125r 5; Cyprus; see also A 125r 11-2, A 24v 9-14, A 92v 5-6), *ουδένας γοιον εμέν δ' είναι να μοιάση* 'there will not be anyone like me' (*Love Poems*, κα' 12; Cyprus; see also ν' 7-8 and ξε' 6-7) etc.

What all the above cases have in common is the fact that the auxiliary is in the third person, appearing in its usual forms *ένι, είναι, είναι(ν)*. In contrast, I have noted only two instances where the auxiliary is declined for person: the first is from the chronicle of Machairas:

- (15) λαλείς πως είσαι να βάλης εις νομήν τον αφέντην μας
You say that you are going to put our master in charge.
(491.28-9; Cyprus, 15th c.)

Dawkins ascribes lexical meaning to the auxiliary: 'you wish to put', but this interpretation finds little support in the preceding theoretical discussion or in the material available from Greek. It is most likely that we are dealing either with immediate or scheduled future, or, at least, with the modality of intention.

The second case, which is also the only example where *είμαι* is combined with the purposive complementizer *ίνα* instead of *να*, is from the *Thanatikon tis Rhodou* by Georgilas (211; circa 1500):

- (16) αμμή εγώ θωρώντα σε είμαι δια ν' αποθάνω
But I, seeing you, deserve to die

However, this structure cannot easily be ascribed future reference.⁵ In fact it is very reminiscent of the equivalent Modern Greek expressions *είναι (για) να τον κλαίνε, είναι να τρελαίνεσαι* etc. where the periphrasis expresses the meaning 'is justified' or 'deserves' (for these expressions and their meanings see LKN, entry *είμαι*).

In texts from the same period (15th – early 16th century) and the same general area (Crete – Cyprus), I have only rarely encountered structures which could be considered to express simple obligation (without the additional meaning of prescheduled future). These are examples 17-20, but in none of

⁵ See also the slightly later (mid-16th century) *αν δεν το κάμω σαν θωρείς, είμαι για να παγώσω* 'If I don't do it as you think right I deserve to freeze' (*Aitolos (Aisopou Mithoi)*, 125 12).

these cases is it possible to exclude a reading from the point of view of ability / root possibility or other modalities:

- (17) Το φυσικόν της αρχοντιάς δεν είναι να κρατήζη
την χρείαν τ' ανθρώπου περιπλιός όντε τη θε ζητήξει
(*Falieros (Istoria kai Oniro)*, 158-60; 15th c.)

The meaning of this couplet, according to van Gemert (1980:147, 187), is that the nobleman, because of his nature, should not (it is not appropriate for him to) refuse help to someone in need, especially if he asks for it.

- (18) δια τρεις αφορμές ένι να φύγωμεν θυμού, μίσου και φάμας
(*Machairas*, 255.11-2; 15th c.)

Dawkins translates (18) as follows: 'There are three ways we may take to avoid wrath, hatred and scandal'. However, as these three ways are not mentioned in the text that follows, I take the meaning to be 'We should avoid (it) for three reasons: wrath, hatred and scandal', in which case the periphrasis has clearly deontic meaning.

Similarly, in the next two examples, hidden behind deontic modality we find the meanings 'it is not right', 'it is not justified', 'does not deserve' (see also 16 above):

- (19) και δεν είναι να τους αποθαρρούμεν. Διати μίαν φοράν ήύραμέν τους δια παράβουλους
And we should not trust them. Because we have once found them to be oath-breakers.
(*Boustronios*, A 108r 5-6; beginning of the 16th c.)

- (20) το λοιπονίν δεν είνε να το θαυμαστή τινάς τούτον το γίνην, ότι αξ αυτόν μου εγίνην
So no-one should be surprised at what happened, because it happened because of me.
(*Machairas*, 251.21-2; 15th c.)

As can be seen from the above examples, all the structures with *είμαι* come from medieval texts that belong to the so-called southern-south-eastern group of dialects. It is characteristic that I could not find even one example of modal use of the present tense of the copula outside this area (e.g. in the *Chronicle of the Morea* or the *Chronicle of the Tocco family of Kefalonia* etc.), with the exception of the archaic infinitive constructions from *Ermoniakos* (examples 12 and 13). Indeed, the relatively frequent appearance of the structures with *είμαι* in the arc Crete-Dodecanese-Cyprus supports the hypothesis that in precisely these areas it is possible to find examples not simply of semantic generalization / reduction (e.g. the use of the copula in place of a modal marker) or decategorization (e.g. the fact that the form used is almost always impersonal) as seen in the above examples, but also cases of phonological reduction of the auxiliary and its coalescence with other grammatical morphemes, for which see below. The fact that all these different aspects of the phenomenon are present shows that the structures in question present an increased degree of grammaticalization, and that we can indeed consider them to be periphrases (for the terminology, see Hopper & Traugott (2003), Bybee, Perkins & Pagliuca (1994), Lehmann, 2002 etc.; for the criteria defining periphrasticity, see Vincent (1987), Bertinetto (1990), Haspelmath (2000) etc.).

In the following examples the auxiliary shows signs of phonological reduction and coalescence with the negative particle:

- (21) «δένα (ed: δεν 'ν' να) βρεθεί και ο Σαπλάνες έχει στο Κολόσσιν κανέναν πράμαν δικόν του»
It will not / is not going to be found that Saplanes has any property of his own at Kolossi.
(*Boustronios*, A 104v 5-6; beginning of the 16th c.)

(See also the same structure in A 130v 9-10; also *νύκταν ημέραν κόβγεις τους και δεν να σε κοζήσουν* '[Death,] you reap day and night and no-one can (is going to) change your mind' (*Georgilas*, 227; circa 1500). In all three examples I think it preferable to reconstruct the complex *δε(ν) εν να > δε(ν)α* with dissimilatory deletion of the first nasal, where *εν* is a common medieval form of the 3rd person singular alongside *έν(ι/αι)* and *είν(ι/αι)* (see Καψωμένος, 1953), rather than to propose a simple future meaning for *να*, the position of which immediately following the negative *δεν* would be in any case problematic. However, the phonological reduction undergone by the auxiliary in this structure cannot really be taken as proof of the grammaticalization of the periphrasis *είναι να* + subjunctive in particular, because in various Modern Greek dialects today, including those in question, we quite

regularly find forms of the negative particle *δένι*, *δέναι* (= *δεν έν(ι/αι)*) (Τζιτζιλής, to appear (a)), so we must conclude that the coalescence of *δεν ένι* is not confined to the periphrases examined here. What these examples show is a general tendency for decharacterization or bleaching of *είναι*. The example given below, however, is a case where the phonological reduction of the auxiliary can indeed be understood as an indication of the grammaticalization of the structure *είναι να* + subjunctive. It comes from Crete:

- (22) Αν απεθάνει η Τάρσια ποιος ένα (ed: *έ' να / έν' <ν>α*) μας γυρεύει
If Tarsia dies, who will interrogate us?

(*Rimada Apolloniou*, A 1213; 15th c.)

The editor of the text takes the meaning of this structure to be simple future (p. 217), and in his comments on the language of the Cypriot Boustronios he adopts the etymology from *(θ)έ(λει)ν να > εν να*, which is the preferred form of the future in Cypriot today, alongside *θεννα*. However, I believe that the degree of phonetic reduction presupposed by this etymology is much greater than that presented in the sources from the southern / south-eastern dialects from this period (see Markopoulos (2009), where it is shown that at least until the 15th century the basic form of the future is *θέλω* + infinitive). Another thing that leads us to reject the interpretation of *εννα* as deriving from the volitional *θέλω* is the large number of periphrases with 'be' in the texts from Cyprus, Crete and the Dodecanese. Taking this into account, the modern futures with *εννα* + subj. in the dialects of Cyprus, e.g. *εν να φάω* 'I will eat' (Χατζηιωάννου, 1999:92) and the Dodecanese, e.g. *εννα χτυπήσεις* 'you will hit' (Παπαχριστοδούλου 1986:181, Rhodes), *γιάαινε κ' εννα 'ρτεί κ' εκείνος* 'Go and he will come with you' (Μηνάς 2002:65, Karpathos) etc. are more plausibly (and more economically) explained as deriving from constructions with the copula rather than the volitional auxiliary. This hypothesis is supported by the existence of futures with 'be' in a number of dialects from Asia Minor, including that of Farasa (Αναστασιάδης, 1976:188-9), e.g. *αρέ ε να νάρτου* 'I'll come soon' (*ε* is a marker of immediate future or obligation⁶ in contrast to the simple future particle *α(ν)*; for the likelihood that *ε* is to be identified with the medieval *εν*, see Τζιτζιλής, to appear (b)), as well as the Cappadocian dialects of Ulagac and Axos (Janse, to appear), e.g. *να έρτομ' δέ 'ναι* 'we won't come' (Ulagac), *να πάμ' δέ 'ναι* 'we won't go' (here *(έ)ναι* is only present in an environment of negation with *δεν*), Propontis Tsakonian, e.g. *μα γράψ' < είμα να γράψου* (Λιόσης 2010) 'I will write', and probably also in the dialect of Silli, for which Κωστάκης (1968:162) gives the form *εννα* (= *θα*). We encounter the same structure in the neighbouring Cyclades, also with the meaning of immediate future, e.g. *να πάου είμαι στο χωριό* 'I'll go soon' (Μάνεσης 1997, 1:307; Mykonos). Here the fact that the copula follows the main verb and is finite, on the model of the simple future as seen in example *να τσι φάς θες* 'I'll beat you' (Μάνεσης 1997, 1:348), excludes the possibility of interference from Standard Modern Greek.

4. Conclusions

In a previous paper (Liosis 2010) I discussed structures of counterfactual modality with the imperfect of *είμαι* in modern Greek dialects, applying the typological division made by Τζιτζιλής (to appear (a)) based on the verb used in each dialect to express this modality. Thus dialects may be divided according to whether they use *ήθελα*, *είχα* or *ήμουν*. In the last category belong, not by chance, Cypriot, Dodecanesian and Cretan, as well as many dialects from Asia Minor (those of Cappadocia, Farasa, Silli, and Propontis Tsakonian). I believe that this picture is confirmed in the light of the data from the medieval texts; the periphrases with the present tense of *είμαι* are generally found in the same areas, are more or less grammaticalized, and cover a broad range of modalities, which theoretically and typologically precede the future (e.g. ability, obligation, possibility), or are later non-future developments (e.g. epistemic modality), or can be described as specialized futures (immediate, scheduled, predestined future). In some cases they have been grammaticalized to the point where they have replaced the simple future.

⁶e.g. *τα ζύα ε να κοπούν σήμουρον* 'the wood must be cut today' (see also the equivalent negative deontic structure from Pontic Greek *κ' έν να γίνεται αέτσ* 'it must not happen like that' (Παπαδόπουλος 1958, 1:288)).

ABSTRACT

In Modern Greek kathe, the lexical paradigm for every, forms expressions with ambiguous interpretations. In this paper we present the different readings kathe phrases give rise to and a way of deriving these different readings through implementing the theory presented in Roussou & Tsimpli (2006) for indefinite phrases. More specifically, it is demonstrated that the different readings attributed to the phrase in question are crucially related to the sentence domain each time the kathe nominal phrase is merged in. When merged and interpreted in dC, the phrase receives a universal distributive “strong” interpretation. When merged in dv, the phrase is bound to receive a “weak”, Free Choice-like interpretation. In dT the phrase may receive either of the above interpretations. Which interpretation the phrase will receive depends on the aspect of the verb and Focus. Focus seems to be related to dC and to the “strong” quantificational reading. I argue that in the case of the ambiguous quantificational expressions in hand the distributive property of kathe interacts with properties of the head of the domain it is merged in and that the relevant readings pertaining to quantification do not involve the Determiner Phrase (DP) as such alone.

Keywords: universal quantification, distributivity, Free Choice, indefinites.

1. Introduction: (In)definites and universal quantification

Since Heim (1982) (in) definites are viewed as variables that should be bound by relevant operators. “Universal” distributive determiner phrases (such as *every*, *each*) have been spared from similar skepticism (unlike collective *all*, cf. Brisson 1998). However, the idea that distributive universal quantification, involving a sorting key and a distributive share (terms by Choe 1985) mainly results from the lexical semantics of the quantifier or determiner of the Quantifier Phrase (QP) or Determiner phrase (DP) which acts as the sorting key has been repeatedly challenged in recent literature.

With the lexical semantics of the “universal” determiners placed under scrutiny, a somewhat different approach rears its head. It has been argued by many that *every* NPs in one way or the other should be treated as similar to other (in)definites, e.g. as variables bound by external operators. The fact that distributivity may ensue with plain plural (in)definites, for example, has been considered as one indication that distribution is not related to a particular determiner forming a DP / QP (Szabolcsi 2010:113):

- (1) (The) six friends watched a movie together and had a glass of wine.

In the above sentence “a glass of wine” is interpreted distributively; we infer that a total of (at least) six glasses of wine were consumed by the six friends, not just one. No overt distributive operator is visible, though.

In this spirit it has been claimed that the lexical semantics of the determiners which form the quantifying DPs or Quantifier Phrases (QPs) are not responsible for the (universal) distributive reading (Szabolcsi 2010, Beghelli & Stowell 1997, Matthewson 2001, among others). The distributive reading is considered to be the result of a sentence-level operator not related to the determiner. All the DP that receives the distributive reading has to do is to merge in the designated syntactic position. In a nutshell, neither the determiner nor the DP are the major culprits; on the contrary, it is a sentence-level operator

that does all the work¹. Evidence for relevant syntactic positioning and the resulting different interpretations comes from Hungarian (e.g. Szabolcsi 1997) and other languages (cf. references for KiLega and Palestinian Arabic in Beghelli and Stowell 1997).

Apart from that, distributivity itself is not viewed as a uniform notion. Different kinds or “degrees” of distributivity have been recognized in the literature. There are a number of differences between strong *every* and stronger *each* - *strong* in Milsark’s (1974) sense, *stronger* as in Ioup’s (1975) hierarchy. According to Heim & Kratzer (1998) *each* is presuppositional, while *every* is not. Tunstall (1998) similarly characterizes *each* as a total distributive; *every* is a partial distributive. According to Beghelli & Stowell (1997) *each* is obligatorily distributive whereas *every* is optionally distributive. Furthermore, as it has been claimed by Schein (1993) and adopted by many semantics researchers ever since (e.g. Kratzer 2003) plurality and any distributivity related to it seem to involve events (Davidson 1967). In this sense again, distributivity is not a matter of the DP alone.

Much of the above discussion and *each-every* distinction have been adopted for relevant Modern Greek paradigms -phrases *kathe* and *o kathe*. Lazaridou-Chatzigoga (2009) and Etxeberria and Giannakidou (2010) distinguish between *kathe* (*every*) vs. *o kathe* (*each*). According to Giannakidou (1998) *kathe* is non-veridical, whereas *o kathe* is veridical. The latter phrase is also attributed an indiscriminative Free Choice (FC) reading (Giannakidou 2012). Considering that Free Choice Items (FCIs) have been regarded as indefinites, this use may be indicative of the indefinite, non-inherently universal nature of the paradigm *kathe* and that is precisely where the main focus of the present paper lies on. I present the different uses of the (*o*) *kathe* DPs and, building on the insights in recent literature discussed, I propose a syntactic analysis for the Greek *kathe* DPs. The phrase’s different distributive readings are attributed to the position the phrase occupies within the sentence and its interaction with (im)perfective aspect and focus.

The discussion is organized as follows: In section 2 we see some facts and core data about the ambiguity of the (*o*) *kathe* DP. In section 3 we review Roussou and Tsimpili’s (2006) proposal on the interpretation of indefinites which we will use as the basis for our analysis. In section 4 we present the data and analysis. In section 5 we conclude.

2. The ambiguity of *kathe* DPs

Modern Greek *kathe* is a distributive determiner (Holton et al. 2007) equivalent to the sorting key (Choe 1985) or distributive-key universal (Gil 1995) *every* determiner.

(*O*) *kathe* DPs are (most commonly) interpreted as universal distributive DPs as in (2, 7). However, when combined with (a certain type) of nominals in particular contexts, they seem to render an FC-*any* interpretation as in (3, 4, 5, 6) below:

- (2) O kathe ipopsifios pire apo ekato evro.
the every candidate receive.past.3sg. from a hundred euro
“Each candidate received a hundred euros.”
- (3) Anighi maghazi o kathe asxetos ke halai tin aghora.
open.pres.3sg. shop every irrelevant and ruin.pres.3sg. the market
“Just any amateur opens a store and ruins the market.”
- (4) Akoma ke o kathe tixeos perastikos tha iksero na su pi ghia tin akropoli.
even and any random passer-by would know.3past.3sg subj. say about acropolis
“Even just any random passer-by would know a few things to say about the Acropolis.”

¹ Szabolcsi (2010) further argues that *every* NPs could be viewed on a par with indefinites on the basis that they both exhibit three common traits: they can be both referentially dependent as they can also be referentially independent. Their distributive scope is clause bounded in both cases. They differ in how the choice function involved in their interpretation is picked (ibid: 105).

Beghelli and Stowell (1997) argue that *every* NP supplies just the domain of quantification and not the universal distributive operator. The latter is not to be found in the determiner’s lexical semantics. It is rather related to a specific position at LF.

Kratzer (2005) puts forth the idea that universal Ds are not inherently universal but agreement markers which participate in a quantificational concord phenomenon similar to negative concord as analyzed in Ladusaw (1994). This idea is also found in Butler (2004) who proposes a feature-based approach for universal quantification.

- (5) Esi bori na min tin skotoses, dhen kseris omos ti bori na katathesi o kathe martiras.
you may subj. not her kill.past.2sg. not know.pres.2sg. what may subj. testify.3sg. any witness
“You may not be the killer, but you can’t be sure what any witness might testify.”
- (6) Tora beni sto dhiadhiktio kathe aniliko ke kani ipoklopes sto Pentagono! # Ine kati poli
sinithismeno.
now get.pres.3sg. in the internet any underage and make.pre.3sg hacking to the Pentagon. Be.
pres.3sg very common.
“Any underage person may nowadays get on the internet and hack the Pentagon. # It is very
common.”
- (7) Kathe aniliko beni sto dhiadhiktio ke kani ipoklopes sto Pentagono. Ine kati poli sinithismeno.
every underage get.pres.3sg. in the internet and make.pre.3sg hacking to the Pentagon. Be.
pres.3sg very common.
“Every underage person gets on the internet and hacks the Pentagon. It is very common.”

The different readings *o kathe* DPs receive are evident in (2, 3, 4, 5), where we encounter an *each* as well as a *just any* and *any* meaning. The different readings *kathe* DPs receive are found in (6, 7). In (4) the item in question is accompanied by words that may be viewed as indicative of the FC indiscriminative reading: *akoma ke* (*even though*), *tixeos* (*random*). The *every* and *each* interpretations anticipated based on the standard view appear only in (2, 7). We observe that in sentences (3-6) where the DP in question receives a Free Choice (FC *any*) interpretation we have a [–perfect(ive)] grammatical aspect on the verb².

Another common trait in sentences (3-6) is that the FCI *kathe*-DP subject is in a postverbal position. Note that the meaning differentiation between (6) and (7) seems to result from the positioning of the subject *kathe* DP in the sentence. The universal distributive reading arises in (7), where the *kathe* DP appears to be in the C domain. In (6), on the other hand, the phrase in question is in a postverbal position in the domain of v, yielding an FC *any* reading. This is not the only difference between the two phrases, however. In (7) the universal strong *kathe* DP seems to carry Focus, whereas in (6) the FCI version does not. Furthermore, if the phrase in question in (6) is pronounced as Focused, its reading becomes strong and universal. Focus seems to be a distinctive feature between the two readings.

The above data clearly indicate that *kathe* DPs receive a Free Choice interpretation³ together with the anticipated universal distributive one (also cf. Margariti 2007). The sections that follow sketch an explanation of the above observations.

3. Background analysis: Roussou & Tsimpli (2006)

Roussou & Tsimpli (2006) in discussing the availability of VSO in Greek and its (relative) unavailability in Italian present a mechanism for deriving the interpretation of subjects (and more loosely all arguments) depending on the domain they occur in.

They divide the clause in three main domains: dC, DT and dv, defined by the heads C, T and V respectively (ibid: 322). The interpretation of a subject indefinite DP varies depending on the domain in which it is merged in. The properties of the head of the domain the DP is each time merged in affect the interpretation of the DP (ibid: 325). They further assume that clitic positions are available in all three domains, forming an iterative ‘clitic-shell’ that appears at the periphery of all domains, adopting a proposal in Manzini & Savoia (2004). In their notation, CL1 and CL2 stand for two clitic positions, roughly corresponding to subject and object clitics, respectively. They propose the following schema

² We have a [–past, –perfect] T specification in (3, 5, 6) and a modal context in (4). According to Roussou & Tsimpli (1996) all verb specifications in Greek but [+past, +perfect] may yield a modal interpretation. This is the case here for (3, 6); we have a modal interpretation, as evident from the English translation. Note that the relation between modality and the [–past, –perfect] specification is in line with Giannakidou’s (2011) claim that [+past, +perfect] is the only true tense in Greek.

³ A few words on what we take Free Choice items (e.g. *whichever*) to be are relevant at this point. Free Choice Items (FCIs) have been argued to be either universal or existential; we opt for the second view and consider FCIs to be existential indefinites in the sense of Heim (1982), following among others Kadmon & Landman (1993), Horn (2000, 2005) and Giannakidou (2001) and Vlachou (2007) for Greek FCIs in particular. If this line of research is on the right track, together with the proposal put forth in Szabolcsi (2010) about the uniformity of *every* expressions with indefinites, we could envisage a unified account for diverse items such as *every*, *any*, *whichever*, and *a*.

for the clause structure, where CL1 and CL2 may be realized by either a clitic or a full DP (their (16), pp. 325):

- (8) [a CL1 – CL2 C [b CL1 – CL2 T [c CL1 – CL2 V]]]

The interpretation of the subject DP is influenced by the properties of the head of the domain it appears in. In dV the event and aspectual properties of the predicate affect the DP. In dT it is the temporal properties of the clause that are relevant, while in dC discourse properties call the shots (ibid: 325).

The theory predicts a number of discrepancies between the three domains, which always pertain to the particular features of the head of each domain.

More specifically, CL1 (“Subject”) and CL2 (“Object”) in dC may alternate in order (SO, OS). Both positions may be lexically realized within this domain. The first in line is the Topic, the second the Focus (following Rizzi 1997).

In dT, CL1 (“Subject”) and CL2 (“Object”) cannot alternate in order. In the presence of a lexicalized CL1, CL2 can only be a clitic. Finally, CL1 and CL2 in Greek can be full argument DPs in dv and alternate in order. Greek allows for a morphological distinction between Nom (S) and Acc (O), primarily due to the full inflection of the definite article at D (while Italian does not have that). Quantification is viewed in connection with the C head and Focus, following previous literature that wants focus in the periphery to be quantificational, in opposition to topic (ibid: 335).

A few words about the general Greek syntax assumed by the two authors and also endorsed by our analysis: For starters, V-to-T movement always takes place. Also, Spec,TP is always projected while preverbal subjects are not always dislocated. The latter assumptions are in pace with Spyropoulos and Revithiadou (2007), contra Philippaki-Warbuton (1987), Tsimpli (1990), Alexiadou & Anagnostopoulou (1998), Spyropoulos & Philippaki-Warbuton (2001), Kotzoglou (2005), among others. They also assume that T-to-C movement may also take place - contra Kotzoglou (2005) and Agouraki (2010) (for Standard Greek) for that matter.

An example of their analysis can be found below (ibid: 328, (their 17(a) and 17 (b)):

- (9) (a) [T Estile [CL1 o Petros [CL2 to ghrama [V tv]]]]
sent-3S the Peter the letter
“Peter sent the letter.”
- (10) (b) [C Estile [CL1 o Petros [CL2 [T tv [CL1 [CL2 to ghrama [V tv]]]]]]]10
sent-3S the Peter the letter
“Peter did send the letter. / Did Peter send the letter ?”

4. Analysis of the subject *kathe* DP in relation to dC, dT and dv

Roussou and Tsimpli (2006) examine Greek DPs with the definite article *o*, *i*, *to* and Bare NPs. We will see how their proposal works with the distributive yet ambiguous *kathe* DP in subject position. Before continuing with the analysis, allow us a last observation. In (6, 7) we saw that the readings for the phrase in question alternated according to its pre /postverbal positioning (of the subject). Here allow us to observe that sentences that are perfectly grammatical with a *kathe* DP as a postverbal subject become ungrammatical when we change the tense specification on T from [–past, –perfect] or [+past, – perfect] to [+past, +perfect]. The data below provide us with a more lucid illustration of the [– perfect] vs. [+perfect] differentiation:

- (11) Me enoxli / me enoxlouse / (* me enoxlise) *kathe* pikramenos vradhiatika sto tilefono.
me annoy.pres.imperf.3sg./ me annoy. past.imperf.3sg. /me annoy past.perf.3sg. any
troubled individual on the phone.
“Any troubled individual can / could annoy me on the phone at night.”
- (12) Den thelo na mou tilefoni /(* na mou telefonisi) *kathe* mathitis mes sto vradhi.
Not want. pres.imperf.3sg. to me.gen call. pres.imperf.3sg. / to me.gen. call.perf.3sg. any
student in the night.
“I don’t want any student to call me up in the middle of the night.”

Based on the above data and adopting Roussou and Tsimpli (2006), we make the following predictions regarding the interpretation of the *kathe* DP in relation to the domain in which it is merged:

If the *kathe* DP is merged at dv, we expect its features to be related to the aspect and event properties of the predicate. I propose that this translates into our distributive DP being interpreted as distributive over events. This concept maybe viewed as similar to that of “domain-widening” for FCIs (Kadmon and Landman 1993). It is the FC interpretation for the *kathe* DP, the only possible when it is merged in the dv domain.

In our analysis we take *kathe* to be lexically specified for distributivity. It is the domain in which this distributive feature is expressed that determines whether this distribution will involve a distribution over events (with plural indefinite reading, and a “usual” reading, as we will see) or a choice over events (Free Choice reading) in dv or distribution over individuals, which, in combination with Focus, will render an exhaustive, universal reading in dC.

If the *kathe* DP is merged in dT, an FC interpretation of the DP in question is attainable only if it has a [–past, –perfect] T specification. A [+past, +perfect] Tense specification makes the [+distributive] feature of *kathe* DP over events impossible, as it only allows the predicate to have the interpretation of an accomplished single event. Thus, the [+distributive] feature in this case may only involve the subject. T is widely assumed to have a special relationship with the subject, in general. Except for this, the DP in question may be interpreted both as a universal and as an FC when in dT. We can assume a lower Focus position in this domain as in Belletti (2004), providing the DP with a [+Focus] feature.

If the *kathe* DP is merged in dC, it can receive both interpretations: A universal, if C is [+Foc] and a topicalized FC or plural indefinite one if C is [–Foc] (provided that T is [–past, – perfect].)

Let us now check how the proposed analysis works with our data: We will examine two sentences: one with a T [– past, – perfect] and another one with a T [+past, +perfect] specification. Each one of them facilitates one of the two readings better than the other for reasons other than syntactic. Let us see a T [– past, – perfect] VSO sentence first (transliterations provided only once for easiness of exposure):

- (13) [T Anighi [CL1 *kathe anerghos* [CL2 *maghazi* [V tv]]]
 [T open.3sg. [CL1 any unemployed [CL2 shop [V tv]]]
 “Any unemployed person may open a shop.”
 “Unemployed people tend to open shops.”
- (14) [C Anighi [CL1 *kathe anerghos* [CL2 [T tv [CL1 [CL2 *maghazi* [V tv]]]]]]]
 “Do unemployed people tend to open shops?”
 “Can whichever unemployed person open a shop?”
 “Does every unemployed person open a shop?”
 “Every unemployed person does open a shop.”

In (13) the CL1 subject *kathe* DP is in dv. Only the FC interpretation is available. In (14) V is in C either because it is focused or because C is [+Q], in which case we have a yes-no question. The *kathe* DP in CL1 in dT may be interpreted as an FC. Alternatively, if we assume a low Focus position in the IP domain (for subjects) as in Belletti (2004), then it can have a universal reading. Let us now check a VOS sentence:

- (15) [T Anighi [CL2 *maghazi* [CL1 *kathe anerghos* [V tv]]]
 “Any unemployed person may open a shop.”
 “Unemployed people tend to open shops.”

In Greek dv CL1 and CL2 may alternate in order due to the fact that Greek DPs, primarily due to the definite article, may check both case and agreement features. Again only the FC reading is available. SVO order is next:

- (16) [CL1 *kathe anerghos* [CL2 C [T anighi [CL1 [CL2 *maghazi* [V tv]]]]]
 “Every unemployed person can open a shop.”
 “Whoever is unemployed can open a shop!”

The subject is in dC, C is [+Foc] and the interpretation is universal. If C is [–Foc] then the interpretation of the CL1 DP here is FC, similar to a Free Relative clause in this case.

- (17) [CL1 *kathe anerghos* [CL2 [T anighi [CL1 [CL2 *maghazi* [V tv]]]]]
 “Every / any unemployed person can open a shop.”

The subject is in dT, the object in dv. In this case, the subject may receive both a universal and an FC interpretation. If it is specified as [+Foc] by a low Focus, then it is universal. If not, it is situated in Spec, TP where it receives an FC (or even a generic-like) interpretation. OVS order is to be checked last:

- (18) [CL2 maghazi [CL1 [T anighi [CL1 [CL2 kathe anerghos [V tv]]]]]]
 “As for shops, any unemployed person can open one.”
- (19) [CL2 maghazi anighi] [CL1 kathe anerghos C [...T tv ...[V tv]]]
 “It is a shop that every unemployed person opens.”

In (18) the DP is in dv, so it receives an FC interpretation. In (19) the DP is in CL1 at the second [+Focus] position in dC, receiving a Universal interpretation. In CL2 we have remnant movement of the IP. A bold proposal, this reading remains problematic, though (as OVS in general).

It is now time we turned to the T: [+past, +perfect] specification. VSO order is examined first:

- (20) *[T pire [CL1 kathe paidi [CL2 mila [V tv]]]
 [T take.past.3sg [CL1 every child[CL2 apples[V tv]]]

The CL1 subject *kathe* DP cannot occur in the dv, where only the FC interpretation is available. In other words, no FC interpretation is available when T has a [+past, +perfect] specification because, according to our initial stipulations, we cannot have distribution over events.

- (21) [C Pire [CL1 kathe paidi [CL2 [T tv [CL1 [CL2 mila[V tv]]]]]]]
 “Did every child take apples?”
 “Every child did take apples.”

V is in C either because it is focused or because C is [+Q], in which case we have a yes-no question. The *kathe* DP in CL1 in dT may not be interpreted as an FC for the reason we just saw. If we assume a low Focus position in the IP domain (for subjects) as in Belletti (2004), then it has a universal reading. VOS is examined next:

- (22) *[T Pire [CL2 mila [CL1 kathe paidi [V tv]]]
 (23) [C Pire CL2 mila] [CL1 kathe paidi [T tv [CL1 [CL2 [V tv]]]]]
 “Every child did take apples.”

The FC reading is not available in the above structure. The universal reading could come up if we assume Remnant movement and CL1 is in dC or, alternatively, in dT in the presence of a low Focus. Let us check the SVO sentence now:

- (24) [CL1 kathe paidi [CL2 C [T pire [CL1 [CL2 mila [V tv]]]]]
 “Every child took apples.”
- (25) [CL1 kathe paidi [CL2 [T pire [CL1 [CL2 mila [V tv]]]]]
 “Every child took apples.”

In (24) the subject is in dC, C is [+Foc] and the interpretation is universal. FC is uniformly not permitted. In (23) the subject is in dT, the object in dv. In this case, the subject may receive a universal interpretation, if it is specified as [+Foc] by a low Focus. Finally, the OVS order:

- (26) *[CL2 mila[CL1 [T pire [CL1 [CL2 kathe paidi [V tv]]]]]
 (27) [CL2 mila pire] [CL1 kathe pedi C [...T tv ...[V tv]]]

The DP is in CL1 at the second [+ Focus] position in dC, receiving a Universal interpretation. In CL2 we have remnant movement of the IP (25).

Reviewing findings and discussion of our analysis, adopting Roussou and Tsimplici's (2006) theory, universal quantification rendered by *kathe* DP is connected to the [+ distributive] feature specification of the *kathe* D and the [+Focus] specification of C in the dC or dT (low focus) domain. The [+ distributive] feature of *kathe* in dV interacts with the event and aspectual features of the V in dv. The [+distributive feature] of *kathe* in dT may also interact with tense features of T. The [+distributive feature] of *kathe* in dC can interact with the [+Focus] feature of C giving an exhaustive reading (cf. the

feature specification of identificational Focus as [+exhaustive], [+contrastive] from E. Kiss 1998). This combination renders the universal reading for the DP⁴.

Summarizing, the *kathe* D is always specified as [+distributive]. Distributivity does not equal universal quantification, however. *kathe* DPs may receive either a universal distributive or an FC (existential) or an indefinite reading. An FC *kathe* DP has the features [–Focus, –perfect] whereas a Universal *kathe* has [+Focus, +perfect] or just any of the two. *kathe* Agrees with [+Focus] on C either in the C domain (dC) in SVO structures or in the T domain (dT) in VSO structures, assuming a low Focus position in the IP area as in Belletti (2004).

5. Conclusions

We have tried in the limited space allowed to sketch an account of the different readings *kathe* DPs exhibit in the framework of Roussou and Tsimpili's (2006) explanation of the Greek VSO. We have attributed the different readings *kathe* DPs receive to the positioning of these phrases in different syntactic domains and to the interplay between the features of the different heads and the [+distributive] feature on *kathe*. This is the only point of departure from the proposals in recent literature on *every* (such as Szabolcsi 2010 and the others cited in section 1), as we argue for a D indeed specified for distributivity, carrying a distributive operator in its lexical semantics. However, the *kathe* D does not contribute a universal operator. In line with these proposals, universal quantification remains mainly the area of responsibility of a sentence level operator in the C domain. More over, the existence of a non overt distributive operator heading (*or occupying the Spec of*) a DistP (e.g. for plain (in)definite distributive readings) is not refuted by the present analysis. In line with the basic tenets of the “deconstructing *every*” recent approaches, we have shown that syntactic positioning does play a crucial role in the emergence of the quantificational readings and that Greek *every* exhibits a behavior very close to indefinites. A number of technical and general issues still remain open for future research and clarifications.

⁴ Among the other issues that the analysis proposed here touches on is the strong preference in Greek for preverbal subjects in transitive constructions and post-verbal subjects in intransitive ones (Laskaratou 1984, 1989), while in subjunctive clauses subjects with neutral intonation can only be postverbal (Spyropoulos and Revithiadou 2007). This may explain why for instance VOS with *take* in (22) is not the most neutral order, while it is with *open* in (15). The fact that the FC *kathe* DP is closely related to a [–past, –perfect] tense specification on T could also be related to a T feature on D, like the *uT* feature on D, which Pesetzky & Torrego (2001) propose as instantiating the nominative case.

LANGUAGE CONTACT IN THE MIDDLE AGES: RHODES UNDER THE HOSPITALLERS*

Theodore Markopoulos

University of Patras, Greece

theomark@upatras.gr

ΠΕΡΙΛΗΨΗ

Το άρθρο διερευνά την έκταση της γλωσσικής επαφής μεταξύ των ελληνόφωνων και των λατινόφωνων (κυρίως Ιταλών και Γάλλων) στη Ρόδο κατά την διάρκεια της κυριαρχίας των Ιπποτών (1310-1522). Υποστηρίζει ότι οι κοινωνιογλωσσικές συνθήκες που επικρατούσαν εκείνη την περίοδο στην πόλη της Ρόδου ευνοούσαν την γλωσσική επαφή ανάμεσα στους δύο πληθυσμούς και την ανάπτυξη διγλωσσίας / πολυγλωσσίας, ιδιαίτερα στον ελληνόφωνο πληθυσμό, που αποτελούσε και την πλειοψηφία. Επιπλέον, επισημαίνεται η επίδραση της γλωσσικής επαφής στα ελληνικά κείμενα της εποχής που γράφτηκαν στη Ρόδο, όχι μόνο στο λεξιλογικό επίπεδο (κάτι αναμενόμενο), αλλά και στο μορφοσυντακτικό.

1. Introduction

Although the diachronic developments of the Greek language have been the subject of investigation for many decades (or even centuries), there is one aspect of the history of the language whose study remains in its infancy: language contact. The historical study of a language is commonly dominated by a political agenda, and in the case of Greek this was translated into a far-reaching attempt to prove the continuity of the language since ancient times, as well as the paucity of external interference (i.e. language contact) in its shaping throughout the centuries. Fortunately, this politically-motivated perspective has receded recently, and as a result, the study of language contact as an important factor for the history of Greek has been gaining ground, partly as a result of the global rise of such studies in the last three decades.

Nevertheless, systematic investigations into language contact phenomena in Medieval Greek are still rare, possibly due to the fact that this period remains under-represented in the diachronic studies of Greek in general. However, there have been recent attempts to tackle such issues for Late Medieval Greek as well (cf. e.g. Markopoulos, 2010, Μανωλέσσου, 2008, Terkourafi, 2005), which is only to be expected if the sociolinguistic situation of the period (ca. 11th-15th/16th c.) is taken under consideration: This was a time when Greek speakers came into close contact with a variety of other languages, as the political situation in the Greek-speaking world after the capture of Constantinople by the Crusaders in 1204 facilitated language contact between Greek- and Romance-speaking populations, which is the main area of interest of this paper.

One such predominantly Greek-speaking area where the local population came into contact with speakers of Romance varieties is arguably the island of Rhodes, which constitutes the focus of this paper. To be more precise, the aim of the article is:

- a) to illustrate the sociolinguistics of the language contact situation that developed on the island from the 14th c. onwards, and
- b) to look into the possible linguistic outcomes of this situation, by highlighting various possible instances of contact interference while paying close attention to a particular morphosyntactic phenomenon, namely the double marking in the comparatives of the adjectives.

* This article is the result of a Marie Curie research project called “Language contact in the eastern Mediterranean in the Late Middle Ages: the Greek perspective”, conducted at the University of Uppsala. Warm thanks are owed to the members of the Greek seminar at Uppsala, as well as to the audience of the Komotini conference, for their helpful comments.

2. Historical background

Rhodes constituted basically a unique political situation, as it was ruled for two centuries (1310-1522) by the Knights of the Order of St. John, commonly called the Hospitallers, who represented a significant political and military power in the Levant from the 12th c. onwards. After their expulsion from the Holy Lands, the Hospitallers were in search of a new strategic stronghold in the eastern Mediterranean. They managed to acquire such a base on 1310, when they captured Rhodes, and consequently most of the Dodecanese, although they were mostly interested in Rhodes and Kos, keeping for themselves the role of distant overlord for most of the other neighbouring islands. They also possessed a stronghold on Asia Minor (Petrouni / Bodrum), and held Smyrna for a limited period of time.

The Hospitallers managed to hold Rhodes against the Ottoman empire for two centuries, before finally having to abandon it on 1523 after a prolonged siege. Thankfully, they were allowed to take their archives when leaving the island, which are still held in Malta. It is only in the past few years that this huge collection of documents had started to be systematically investigated, and very little has been done concerning: a) the situation of the Greek-speaking population under the Hospitaller rule,¹ and b) the language situation on Rhodes. This paper, as already stated, seeks to address these issues by focusing first on the sociolinguistic situation, and secondly on linguistic features of texts produced on the island, in an attempt to establish the extent of language contact phenomena on Hospitaller Rhodes.

3. Language contact: the sociolinguistic facts

3.1 General remarks

The little that is known with regard to the sociolinguistic aspects of life during the Hospitaller rule concerns the town of Rhodes, the capital of the island. Consequently, the discussion that follows (based mostly on Luttrell, 1982, 1992, 2003, 2007, Borchardt et al., 2007, and Τσιρπανλής, 1991) concerns the town itself, which is the most interesting social environment from a language contact perspective anyway, since it represented the multiethnic, multilingual port-city of the late medieval Mediterranean where contact between various populations must have thrived, at least with respect to specific registers (such as maritime talk). Moreover, settlements of Romance speakers in the Rhodian countryside must have been rather sparse, rendering thus the town as the only or at least the major point of language contact on the island.²

The Knights themselves lived in the *collachium*, a walled area inside the town. It is clear, however, that not only Knights lived in that area, as other Latins and Greeks lived there side-by-side. The town (*burgo*) was populated by Greeks (artisans, traders etc.), which apparently constituted the clear majority of the inhabitants, but an unknown number of Latins also lived there: Italians (Genoese mainly), French, Catalans etc. in a variety of professions, such as traders, notaries, and mercenaries. The well-documented presence of Turks, Armenians and Jews in the town should be noted as well.

The Greeks were in relatively good terms with their Latin overlords, as we can tell from the fact that no open uprising against the Knights has been recorded (only a minor one in Kos, in the early 14th c.). This peaceful co-existence was probably fuelled by the ever threatening presence of the Ottoman empire, as well as by a system of political representation put in favor of the Greeks by 1380 at the latest.

So, all in all, some facilitating factors for language contact between Greeks and Latins in the Hospitaller Rhodes can be isolated: a) They lived side-by-side in the close quarters of the town, and this spatial proximity may well have ended in closer communication between the two parties, b) Various commercial activities involved both parties, c) There was very limited social unrest, which

¹ A. Luttrell, M. Heslop and G. O'Malley are currently working on a project about the countryside of Rhodes during the first century of the Hospitaller rule, which should shed some light on this issue. The publication of the volume coming out of the project is very eagerly anticipated.

² This is a point worth recalling when talking about the influence of this medieval language contact situation in the modern Greek dialect of Rhodes. In other words, absence of interference phenomena in the modern dialect, represented mostly by countryside varieties, is only to be expected given the situation in late medieval Rhodes, and cannot be taken as proof for a supposedly limited influence of language contact in the dialect of Rhodes as a whole.

otherwise could have resulted in a communication “breakdown” between the two linguistic and cultural groups.

3.2 The Latin side

Almost nothing has been done to determine whether language contact between Greeks and Latins had any effect on the Romance languages as spoken (and written) on the island. It is fair to say though that, given the cultural integration of the two groups observed at the latest stages of the Hospitaller rule (cf. further below), Greek interference on Romance varieties of Rhodes seems more than plausible. The topic goes beyond the scope of the paper, but some preliminary remarks are in order here.

First of all, there is ample evidence to suggest that a smaller or larger part of the Latin population residing in the town of Rhodes learned Greek. Pre-eminent among them was the group of notaries working for the Knights: some of them could translate from Latin (or Italian) into Greek or vice versa, as can be seen from 15th c. documents, which are really important in establishing any language contact phenomena on the island (cf. section 3). Moreover, the co-habitation of the town by Greek- and Romance-speakers led inevitably to mixed marriages, whose offspring, being of mixed descent, may well be bi- or multi-lingual. This could only strengthen knowledge of Greek among the Western population of the island.

What about the Knights themselves? It should be borne in mind that the Knights were a multilingual group, with French being the dominant language among them initially, and Italian being also used widely. They had no great scholarly reputation, and apparently were not very eager to pick up Greek: they were unfamiliar with the local language in their majority. On the other hand, there is evidence that at least some of them learned to speak Greek, while Master Juan Fernandez de Heredia was interested both in ancient and in medieval Greek texts (cf. Luttrell, 1960). As expected, knowledge of Greek among the Knights must have widened with the passage of time, as the two dominant groups of the island (Latins and Greeks) overcame many of their cultural differences to create a community with tighter cultural and financial bonds. This is manifested in the rather surprising fact that at the very end of a 16th century manuscript (Montp.S.Medic. 4056), containing among others the poems of the 14th century Cretan poet Sachlikis, the following note is found:

- (1) «Ετελειωθει ο ζαχλικης δια χειρος εμου φρα νοελ δε λα μπρω εκ της ροδων καβαλλαρεις τελος. Ει χηρ μεν η γραμματα σεπτειται ταφω η γραφη δε μενουσα εις χρονους πλιροστατους».
 “Sachlikis was finished by my hand, fra Noel de la Broue, knight from Rhodes. End. The hand that writes decays(?) in the grave but what is written lives forever long”

This Knight, Noel de la Broue, is otherwise unknown to us, as he is not included in the Knights’ catalogues that remain from that period. Nevertheless, this note illustrates the partial cultural osmosis argued for above: at the later stages of the Hospitaller rule, some Knights were not only able to speak Greek, but also interested enough in medieval Greek literature as to copy/write a manuscript containing such works. The fact that the manuscript is full of phonological and syntactic irregularities (Παναγιωτάκης, 1987) does not undermine this conclusion, but simply points out the fact that Noel de la Broue was not a learned man, a scholar in Greek, but must have learned Greek in his everyday-spoken- affairs, providing an example of the results that the multilingualism in town must have brought about.

To sum up, there is solid evidence to argue for bi-/multi-lingualism from the part of Latin speakers on Rhodes, including a –rather modest- number of Knights. The effect of this contact situation on the Romance varieties spoken on the island remains unknown. Multilingualism must have spread with time, as the Latin speakers came closer in cultural terms with the Greek majority of the population. However, it should be stressed that, contrary to the massive shift from Italian - French to Greek that occurred in Crete and Cyprus respectively, no such development can be seen in the case of Rhodes. Apparently, the cultural osmosis between Latins and Greeks did not have the necessary time to give such drastic linguistic results.

3.3 The Greek side

There is plenty of evidence in favour of the idea that a considerable number of Greeks were at least bilingual, i.e. they spoke a Romance language (Italian and/or French) as an L2. It is important to note that this instance of bilingualism must have encompassed various aspects of social life:

i) Household: It is well known that many Greeks made their living as servants in Latin houses. Many of them were slaves imported from other Greek-speaking areas. It is easy to imagine that at least a number of them had a passive familiarity with a Romance language, in order to be able to communicate and perform the daily chores. In this way, they were part of the households, and they had the opportunity to practice their L2 knowledge every day.

ii) Marine life: A lot of Greeks were *marinari*, in other words they were obliged to serve for a length of time in the ships of the Hospitallers. It is more than plausible that they learned some sort of marine language while they served. It is also noteworthy that some Greeks even collaborated with Latins in their maritime activities, and obviously this presupposes an open channel of communication between them. This involvement of Greeks with Western sea-traders is very well exemplified in the interesting case of Michael of Rhodes (cf. Long et al., 2009). Michael was a Greek citizen of Rhodes, and we know of him because he wrote in Italian (Venetian) a manuscript containing a portolan, a treatise on shipbuilding and some personal notes from his travels.³ He ended his career as a galley commander for Venice, a feat that would have been impossible without his solid knowledge of the Italian dialect.

iii) Other professions: Many of the citizens in the *burgo* might also have developed some bilingual skills, depending on whether their profession was of any relevance to the Knights or to the wider Latin community. One such individual was apparently Ayme Cassien, a Greek falconer in the service of the Hospitallers. We hear about him indirectly, through a well-known falconry book written by Jean de Fransières (late 15th c.), *Le livre de fauconnerie*. According to de Fransières, he partly based his own book on a previous similar treatise by Ayme Cassien, who must have written his own work in the early 15th century in French.⁴

The case of Ayme Cassien is reminiscent of the story of Michael of Rhodes: they were both bilinguals, with a solid knowledge of French and Italian, respectively, which helped them make their way into the world. It is not difficult to imagine that the group of bilingual Greek speakers with similar aspirations and professional achievements must have been larger, although it is not easy to determine its exact size.

iv) Another such group, perhaps the most important one from a language contact perspective, consists of the notaries who worked in the service of the Knights. There is evidence of a Greek notary already from the mid-14th century, who was appointed to translate various mandates and court decisions from Latin (or French / Italian) into Greek. It is unfortunate that most of these translated documents have not survived, but the few remaining can shed important light on the written variety of the period. It is obvious that this variety was partly based on the Latin / French “*officialese*”, containing various loanwords and calques. Since the notaries must have also served for the writing down of contracts and agreements among the town-dwellers (at least), the variety they used must have constituted an important part of the ‘norm’, influencing thus other spoken and written varieties.

Greeks were also needed for communication and diplomatic relations between the Knights and the Ottoman rulers. All correspondence was conducted in Greek, and various agreements were translated from Greek into Latin / Romance, providing us with interesting material (cf. further below).

On the whole, there is considerable evidence of multilingualism from the Greek part of the population, on various social channels. The knowledge of Italian and / or French could mean a brighter future for the Greeks of Rhodes, and it is probable that a considerable number of them attempted to take advantage of it.

4. Language contact: linguistic facts

It has been established that multilingualism was enough widespread among the Greek population (particularly in the town of Rhodes) for contact interference phenomena to appear on the Greek variety of the island. Unfortunately, this is not very easy to substantiate, since the extant material is very thin and one has to work with admittedly much less than required in order to draw any solid conclusions. To be more precise, the only literary material surviving from the Hospitaller Rhodes are the writings of E. Limenites (“The plague of Rhodes” and possibly 1-2 other works), and some folk songs originating probably from the Dodecanese. As to the non-literary material, the archive of the Knights (as already

³ His manuscript is interspersed with short prayers in Greek, hence our certainty about his native language and his religion.

⁴ This is not really known, but is very possible since the profile of de Fransières does not match with him speaking Greek; furthermore, it is unlikely that he would have failed to mention the fact that he translated Cassien’s treatise from Greek into French (cf. Wistedt, 1967).

stated) contains mostly documents in Latin, and very few documents in Greek. Still, they constitute our basic source of non-literary material, together with documents related to the diplomatic contacts between the Knights and the Ottoman Turks surviving in the Turkish archives.

The question is, given the sociolinguistic situation described above, what would be the expected result of this case of language contact? Obviously, one can expect a considerable amount of lexical borrowings from Romance languages into Greek, given the partial/full bilingualism of the Greek speakers and the social prestige of the Romance languages on the island. And this is exactly what is found in Limenites, which contains a great number of loanwords, such as: *μπουρνάλα* (sword < It. *pugnale*), *φέστα* (fest, <It. *festa*), *μανιγόρδος* (gravedigger, <It. *manigoldo*) and many more. The same applies to the non-literary documents, where Italian loanwords abound, e.g. *βηζαρίσει* (= notify), used as a translation of the It. *notifichera* (Τσιρπανλής, 1968, B'): it is noteworthy that *βηζαρίσει*, itself a loanword, is given as the Greek equivalent of an Italian word, which illustrates its already established status in the Greek lexicon of the period.

More interestingly, one could also expect some morphosyntactic interference, especially in three different instances: a) in the Greek variety spoken as a second language by Romance speakers (cf. e.g. Thomason, 2001 on interference through shift and the possibility of syntactic transfer even prior to lexical borrowing), b) in translations from Italian / French into Greek, possibly as an effect of the specific genre, and c) in the case of full bilingual Greek speakers, where syntactic calquing might have been an option in certain communicative circumstances.

The second instance is represented in (2) below, an example taken from a document that survives in both an Italian and a Greek version, where the preposition «*από*» is used as an equivalent for the Italian preposition «*de*»: but this equivalence does not hold in this syntactic environment:

(2a) «... και να δίδη πάντοτε μαντάτον από κουρσάρικα κατελάνικα»

(2b) «... e che sempre auisi dele fuste de corsari Catellanj...»

“and to always give notice about Catalan corsair ships”

(Τσιρπανλής, 1968, A' 13)

This semantic correspondence does not hold in this context, though: the Greek preposition, contrary to the Italian one, was not normally used to convey the meaning of ‘reference’, so the example illustrates nicely a case of syntactic interference.

Another possible instance of syntactic interference can arguably be seen in the case of the analytic comparatives of the adjectives. There is some controversy regarding the emergence of the comparative marker ‘*πιο*’ in Greek and whether it is a loanword from the equivalent Italian ‘*piu*’ or whether the whole analytic comparative construction in Greek was built on the Italian model. Jannaris (1897) assumed an Italian origin, although he gave no arguments for this assumption, and no real progress has been made since concerning the issue (cf. Χειλά-Μαρκοπούλου, 1990). Regarding the earliest known examples of this analytic comparative construction, Kriaras’ dictionary gives examples of ‘*πλια/πια* + Adjective (either positive or comparative degree)’ for the formation of the comparative and superlative starting from the late 16th century.⁵

There is some interesting evidence on this construction in the non-literary documents coming from Rhodes. The diplomatic correspondence between the Master Pierre d’Aubusson and the Ottoman rulers contains three instances of the new analytic comparative formation, two of which involve the use of the comparative form of the adjective together with ‘*πια*’, as in (3):

(3) «...διατιν το τέλος τις πραξης αυτις θοροντα υνεη πρμα πια καλιωτερα να τελιοθη μετα τον...»

“because the end of this affair, as we believe, is something that should better end with him... = because we believe this issue should end with his participation”

(Lefort, 1981 / 21, d. 1489)

This example is taken from a document written possibly by a Latin, since it contains not only numerous grammatical and syntactic problems, but also some writing peculiarities that support the theory of a non-native scribe. According to my knowledge, together with the other two similar instances in the same archive (Lefort, 1981: 15, 18), it constitutes the earliest attestation of such construction by a margin of at least a century. Is it coincidental that it occurs in Rhodes during this

⁵ The form ‘*πιο*’ must derive from the earlier attested ‘*πια*’, which in its turn may have derived from the form ‘*πλια*’. It is not clear whether the Italian form ‘*piu*’ constituted the phonological model for the derivation of ‘*πια*’ from ‘*πλια*’. This paper is mostly interested in the syntactic/semantic equivalence of the two constructions, so the phonological issue will be left aside.

period of language contact, when Italian was the dominant Romance language on the island?⁶ It is also telling that all of Kriaras' examples come from Crete or Cyprus, i.e. areas of strong contact situations between Greek and Italian. Note that the literary texts from Rhodes contain two more instances of this construction, the one involving the positive degree of the adjective ("The plague of Rhodes", 123) and the other the comparative degree ("Love songs", 42).

It has been convincingly demonstrated (Heine & Kuteva, 2006) that the development of an analytic comparative construction is very common in situations of language contact across Europe. The double marking of the comparison (i.e. with a comparative marker being added to an adjective in the comparative degree) can be considered as one of the common stages of this development, which eventually wears off. This description fits well with the Greek data, strengthening the plausibility of a language contact account for this construction.

In this scenario, the L2 Greek speakers probably formed this construction, through interference from their L1 (Italian). Their imperfect learning is probably manifested in the double marking of comparison, which was subsequently restricted with the diffusion of the construction in the native Greek population. Obviously, much more evidence is needed in order to argue convincingly for a contact account for this morphosyntactic development in Greek; but it has been shown that the earliest attestations of an analytic comparative construction can be found in the material from Hospitallers' Rhodes, which, given the morphosyntactic and sociolinguistic context of these attestations as explained above, can be supportive of a language contact origin.

On the whole, the evidence for lexical borrowing is solid, while morphosyntactic interference is much more difficult to prove, especially with such a limited material. However, there is evidence of such an effect on a small scale, while large scale effect (for instance, the emergence of a new comparative construction) is also likely, but not certain yet. Further investigation is needed and more examples of such developments are to be found in order to substantiate the case for morphosyntactic interference from Romance languages in the Greek variety spoken in the late medieval (town of) Rhodes.

5. Conclusions

The Hospitaller rule favoured in many ways the development of a multilingual society in the town of Rhodes itself. Therefore, it comes as no surprise that, according to the available sociolinguistic evidence, a situation of rather intense language contact between Greeks and Latins must have developed inside the *burgo* of Rhodes. This assumption is corroborated but only partly by the linguistic record, which is poor, but it still contains evidence that language contact influenced the variety of Greek spoken (and more clearly written) on Rhodes, primarily (but probably not exclusively) on the lexical level. An interesting case of possible morphosyntactic interference has been isolated, namely the emergence of the analytic comparative involving the marker 'pio', but more evidence is needed to argue convincingly for a contact – related development.

By the early 16th century, the cultural osmosis that must have gone a long way on Rhodes was also evident in the use of language on the island. Two inscriptions bear witness to this development: the phrase 'PALI THARO' (=courage again) used as a personal motto by the Knight Jacques de Bourbon in a coat of arms of the late 15th century; and a cannon cast of the early 16th century found with the signature 'ΤΕΩΠΓΙΟΣ ΛΑΜΠΙΑΔΗΣ ΝΤΕ ΡΟΔΩ', with the exceptional mixture of a Romance preposition (NTE – de) with the highly archaizing Greek Dative ending '-ι' in the word 'ΡΟΔΩ'. As always, language contact had some unexpected results.

ABSTRACT

This paper discusses methods for automatic acquisition of bilingual corpora from the Web. Given the vast number of documents available online, the Web could be considered an excellent pool for extraction of valuable data for linguistic purposes. Therefore, methods for creating such corpora, especially when targeting less-resourced languages like Greek, can be of great value. Besides presenting a general workflow for constructing collections from the Web, this article describes our work to produce collections of English/Greek comparable documents in the “Political News”, “Technological News”, “Sport News”, and “Renewable Energy” domains and parallel resources in the “Environment” and “Labour Legislation” domains.

1. Introduction

There is a growing literature on using the Web for constructing large comparable and parallel collections. Such resources can be used by linguists studying language use and change (Kilgarriff and Grefenstette, 2003), and at the same time be exploited in applied research fields like machine translation, cross-lingual information retrieval, multilingual information extraction, etc. Moreover, these large collections of raw data can be automatically annotated and used to produce, by means of induction tools, a second order or synthesized derivatives: rich lexica (with morphological, syntactic and lexico-semantic information) and massive bilingual dictionaries (word and multiword based) and transfer grammars.

We adopted two different strategies in order to acquire large-scale collections from which many parallel sentences could be extracted. The first method, used for the “Political News”, “Technological News”, “Sport News”, and “Renewable Energy” domains, employs a focused crawler, i.e. an engine which starts from a few seed URLs and “travels” on the Web to find web pages in the targeted languages and relevant to specific domains (Menczer et al, 2004).

The second approach, used for acquiring parallel resources in the “Environment” and “Labour Legislation” domains, exploits a similar crawler that targets known bilingual web sites and extracts pairs of documents that are likely translations of each other. Both approaches integrate tools for text normalization, language identification, and text classification. Following the crawling process, our system filters stored pages in order to discard duplicates and keep only documents rich in textual information. The implemented components for corpus acquisition are available as web services at <http://nlp.ilsp.gr/soaplab2-axis/>.

The organization of the rest of the paper is as follows: In Section 2, we refer to recent related work. In Section 3, we describe in detail the proposed workflow to construct comparable corpora. A modification of this workflow with the purpose of acquiring parallel data is presented in Section 4. Conclusions and future work are discussed in Section 5.

2. Related Work

Several publications concerning the exploitation of comparable and parallel corpora can be found in the related literature. A framework for exploiting comparable and parallel corpora for generating named entity translation pairs was introduced by Hassan et al. (2007). Tao and Zhai (2005) presented a method for examining frequency correlations of words in different languages in comparable corpora in order to

find mappings between words and achieve cross-lingual information integration. Munteanu (2006) attempted to extract parallel sub-sentential fragments from comparable bilingual corpora using a signal-processing approach for producing training data sets for MT systems.

On the other hand, the number of available publications that address the issue of building such corpora is very limited. A report on different methodologies used to collect small-scale corpora in nine language pairs and various comparability levels was reported by Skadiņa et al. (2010) and the collected corpora were investigated for defining criteria and metrics of comparability. Resnik and Smith (2003) considered the Web as a parallel corpus and proposed a method based on the similarities of the HTML source in order to detect parallel web pages. A similar approach was implemented recently by Esplà-Gomis and Forcada (2010) and was delivered as the open source project called Bitextor¹.

Early approaches were based on readily available resources. Sheridan and Ballerini (1996) introduced an approach for multilingual information retrieval, applying thesaurus-based query-expansion techniques over a collection of documents provided by the Swiss news agency. Braschler and Scäuble (1998) presented a corpus-based approach for building comparable corpora using the TREC CLIR data while Talvensaaari et al. (2007) presented a study which described how a comparable corpus was built from articles by a Swedish news agency and a U.S. newspaper. An initial work on acquiring comparable corpora from the web was reported by Utsuro et al. (2002). They collected articles in Japanese and English from News web sites and attempted to align them based on their publication dates. Ion et al. (2010) presented a customizable application that could be used for building comparable corpora from Wikipedia and the web by merging and organizing different web crawlers. Talvensaaari et al. (2008) used a focused crawling system to produce comparable corpora in the genomics domain in English, Spanish and German languages. Even though our work follows the same methodological approach, two critical differences are: i) less-resourced languages are targeted, which significantly increases the challenge of this task and ii) a number of different topical domains are crawled extensively to produce the final results.

3. Building Comparable Corpora

Based on the assumption that documents in different languages and in a specific narrow domain could be considered comparable, we adopted a strategy consisting of two separate monolingual domain-specific crawls, one for each language. Given that each crawl provides documents relevant to the narrow domain, we believe that several parallel sentences or phrases could be extracted from the final bilingual collection. The workflow for acquiring monolingual domain-specific data is illustrated in figure 1 and each module and required resource of the focused monolingual crawler (FMC) is discussed in the following subsections. FMC is available as web service at <http://nlp.ilsp.gr/soaplab2-axis/> under the name *ilsp_fmc*.

3.1 Construction of Topic Definitions

A critical issue in focused web crawling is the creation of the topic definition, since each web page visited by the crawler should be classified as relevant to the topic or not with respect to this definition. To this end, we adopted a strategy followed by many researchers (Ardö and Golub, 2007; Dorado, 2008), i.e. to use triplets (<term, relevance weight, topic-class>) as the basic entities of the topic definition. The relevance weight is a manually given score, positive or negative; a positive score indicates the relevance of a given term to the topic; a negative score denotes terms that are likely to occur in documents of similar and/or irrelevant domains. For example, the term “biodiversity” is closely related to the “Environment” domain and so has a large positive weight, while the term “heavy metal” could have a low positive weight denoting that this term is a common term in documents about deterioration of the environment, or a negative weight since this term is frequently met in documents about music genres. Topic-classes correspond to possible sub-categories of the target domain. For instance, “labour law and labour relations” and “personnel management and staff remuneration” could be two sub-classes of the “Labour Legislation” domain. By using the topic-classes each document under consideration is not only classified as relevant to the domain or not, but it is further categorized into a specific sub class. Introducing sub classes in a topic definition effectively prevents the bias of the

¹ <http://bitextor.sourceforge.net/>

collection to a specific sub class (i.e. by applying a post-processing task that selects equal amount of documents from each sub class).

Topic definitions can be constructed by manually selecting a representative set of words or multiword expressions. Online resources (e.g. Eurovoc multilingual thesaurus² was employed in our work) provide sets of terms in different languages assigned in specific thematic categories and therefore can greatly assist in this process. Alternatively, a topic definition can be automatically extracted by small topic-specific corpora using tf-idf and term extraction algorithms.

3.2 Construction of Lists of Seed URLs

Similarly, an initial seed URL list for the English language was assembled during the topic definition construction. To expand this list, we employed a custom version of the BootCat toolkit (Baroni and Bernardini, 2004). Using random tuples (i.e. n-combinations of terms) from the terms included in the topic definition, queries were run on the Google search engine and the resulting URLs were added to the seed list.

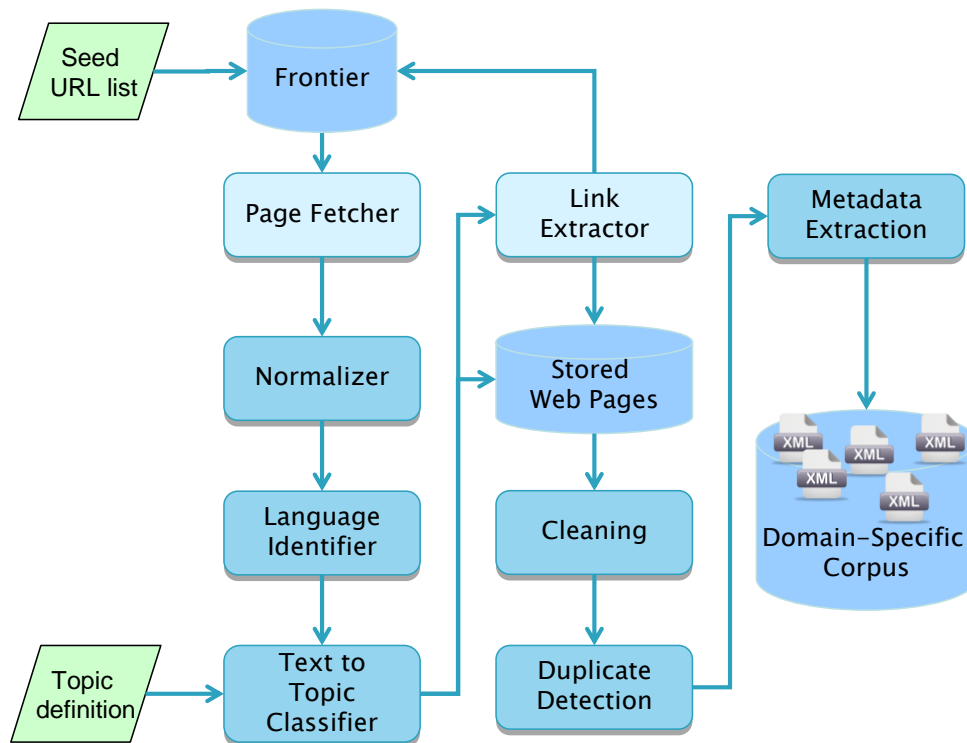

Figure 1 Workflow for acquiring monolingual domain-specific data

3.3 Focused Monolingual Crawling

The focused monolingual crawling is an iterative procedure that includes several steps of processing the content of the visited web pages. The schedule of the FMC is called the Frontier; the list of URLs to be fetched in each iteration. Initially, the Frontier contains the seed URLs. Then, the FMC visits these web pages, extracts their links and estimates a relevance score for each of these links (see subsection 3.3.3 below). Next, the links are sorted according to these scores and the most promising links (i.e. the

² <http://eurovoc.europa.eu/>

links originated from very relevant pages, or contain terms in their surrounding texts) are selected and fill the Frontier for the next iteration.

3.3.1 Text Normalization

The text normalization phase involves detection of the formats and text encodings of the downloaded web pages as well as conversion of these pages into a unified format (plain text) and text encoding (UTF-8).

3.3.2 Language Identification

In the language identification phase, each downloaded web page is analysed and its language is identified. Documents that are not in the target language are then discarded. Lingua:Identify, an open-source and flexible language identifier based on n-grams, is used for this task. Lingua:Identify did not originally support the Greek language; we provided the author of the tool with a small corpus of Greek texts (taken from JRC Acquis) and a new version of the identifier was released and used throughout the subsequent work. In order to remove parts of text that are not in the targeted language, the embedded language identifier applied at paragraph level as well. Any paragraph that is not in the targeted language is annotated paragraph as “out of interest”.

3.3.3 Text Classification

The next process in the proposed pipeline is a text-to-topic classification module. Each crawled, normalized and in-target language web page is compared with the topic definition by exploiting a simple string-matching algorithm. By adopting the method described in (Ardö and Golub, 2007), the score of relevance s for each web page is calculated as follows:

$$s = \sum_{j=1}^4 \sum_{i=1}^N \frac{w_j^l \cdot w_i^t \cdot n_{ij}}{l_j}$$

where N is the number of terms in the topic definition, w_j^l denotes the weight assigned to each location j of the HTML page (i.e. 10 for *title*, 4 for *metadata*, 2 for *keywords* and 1 for *main text*), w_i^t is the weight of term i , n_{ij} denotes the number of occurrences of term i in the location j , and l_j is the number of words in the location j .

The calculated score models the likelihood that the page under consideration contains text relevant to the target domain. Therefore, if the score of relevance is under a predefined threshold, the page is classified as irrelevant and discarded. Otherwise, the page is stored and its links are extracted and added to the list of scheduled to be visited links. The selection of a high threshold, although it ensures that the acquired pages contain rich in-domain content, have proven to sometimes “choke” the crawler since it is often the case that pages which meet this criterion cannot be found without first visiting less relevant web pages. To overcome this shortcoming, we adopted the “tunneling” algorithm according to which the crawler will not give up probing a direction immediately after it encounters an irrelevant page but will continue searching in that direction for a pre-defined number of steps. This allows the focused crawler to travel from one relevant web cluster to another when the gap (number of irrelevant pages) between them is within a limit.

Since it is not feasible to find all the web pages that exist in the Web and are relevant to a specific domain, the recall of the embedded text to topic classifier is not a critical measure. On the contrary, precision is of significant value, since the constructed corpus consists of documents that have categorized as relevant. In order to favor precision we made the classifier stricter by introducing an additional relevance score which is based on the amount of unique terms that exist in the main content of the page.

3.3.4 Boilerplate Removal

Web pages often need to be cleaned from elements that are irrelevant to the content (see figure 2) like navigation links, advertisements, disclaimers, etc. (often called boilerplate). Since we aim to collect comparable corpora useful for linguistic purposes, such parts of the HTML source are usually redundant. Therefore, they were detected and marked as “boilerplate” by employing the Boilerpipe tool (Kohlschütter et al., 2010), which uses a set of shallow text features (link density, number of words in text blocks, etc.) for classifying individual text elements in a web page as boilerplate.

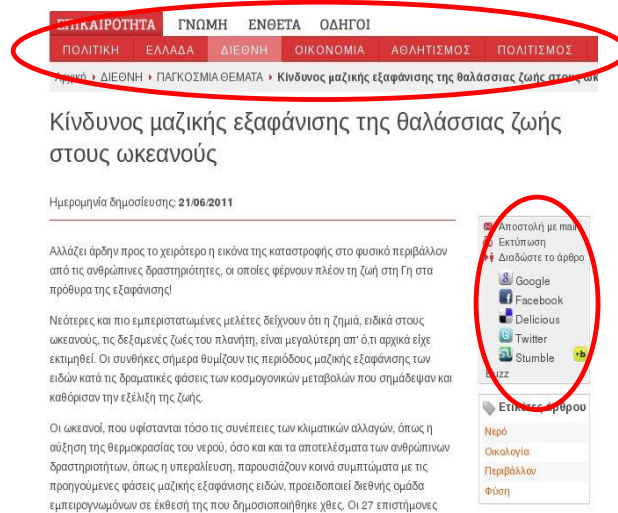

Figure 2 Boilerplate of a web page

3.3.5 Duplicate Detection

In (near) duplicate detection each new candidate document is checked against all other documents appearing in the corpus (i.e. by document similarity measures) before being added to the collection. An efficient algorithm for deduplication, which is implemented as an open source tool, is SpotSigs (Theobald et al., 2008). The algorithm represents each document as a set of spot signatures. A spot signature is a chain of words that follow frequent words as these are attested in a corpus. SpotSigs classifies documents with respect to the cardinality of their set of spot signatures and so significantly reduces the time complexity.

3.3.6 Metadata Extraction

In this task, the HTML source of the stored web pages is scanned and the available metadata (i.e. original URL, keywords, title, etc) are extracted. In addition, the structure of the web page is detected and a special attribute (i.e. title, listitem or heading) is added to each paragraph. Parts of such an XML file are presented in the following example:

```

3.4 Acquired Comparable Corpora

We employed the described workflow for automatic collection of comparable corpora. Texts were collected in the domains of Renewable Energy (RE), Political News (PN), Sport News (SN) and Technological News (TN) and in two languages: English (EN) and Greek (EL). To strengthen the comparability rank of the collected corpora, further sub-categorization was enforced on all domains. Table 1 shows the subclasses selected for each domain. Table 2 illustrates the quantities of the acquired resources in the selected language pairs and domains.

By comparing the number of tokens in EN and EL for each domain, one could observe the great variation of the corresponding ratios (i.e. 0.9/19 << 10.2/25.7 << 13.5/8.8). This occurs due to the fact that the crawler acquires resources in the selected language pairs and domains without taking into account the rank of comparability of the acquired documents. Therefore, the acquired collections include both strongly and weakly comparable documents. A particular tool that identifies

strongly/weakly comparable documents could be used to construct specific collections as subsets of the acquired data.

Domain	Subclasses
RE	Wind power Hydropower Solar energy Biomass Biofuel Geothermal energy
PN	Ireland bailout Google faces competition inquiry Leaving the euro
TN	iPad models, presentations and reviews iPhone models, presentations and reviews Facebook and privacy issues
SN	Football and the Barcelona – Real Madrid match (29/11/2010) Tennis and the ATP World Tour Final between Federer and Nadal Ice hockey and the Vancouver 2010 Winter Olympics tournament

Table 1 Domains and subclasses

Language pairs (L1-L2)	Domain	# of tokens in L1 (Mt)	# of tokens in L2 (Mt)
EN-EL	RE	19	0.9
EN-EL	PN	25	25.8
EN-EL	TN	25.7	10.2
EN-EL	SN	8.8	13.5

Table 2 Quantitative information for acquired comparable data. (figures in Mega tokens (Mt)).

4. Building Parallel Corpora

This section describes the required modifications of the proposed workflow in order to acquire parallel documents from the web. To this end, another component called Focused Bilingual Crawler (FBC) was implemented and is available as web service at <http://nlp.ilsp.gr/soaplab2-axis/> under the name *ilsp_bilingual_crawl*. The first requirement concerns the seed URL list; these lists should consist of links pointing to web pages that are relevant to a predefined domain and originated from multilingual web domains. In general, the construction of such lists is a time-consuming process, which is being performed manually. Then, the crawler starts from an initial URL, and in a spider-like mode finds the links within these pages pointing to pages inside the same web site, visits the new pages and so on.

Following the same processing steps, each web page is normalized and its language is identified as explained in subsections 3.3.1 and 3.3.2 respectively. If the detected language is one among the targeted languages, the web page is further processed by the text-to-topic classifier. Since the document could be in any of the two languages, the topic definition should be bilingual (i.e. the new list of terms is the union of the two corresponding monolingual topic definitions).

To this end, the collected documents are in the targeted languages, originated from the same web site and are relevant to the selected domain. In order to identify pairs of web documents that could be considered as translations of each other, an additional module is required. A well-known tool that meets this need is Bitextor (Esplà-Gomis and Forcada, 2010). For each candidate pair of documents, the relative difference in file size, the relative difference in length of plain text, the edit distance of web page fingerprints constructed on the basis of HTML tags, and the edit distance of the lists of numbers occurred in the documents are examined. If all measures are under the corresponding thresholds, the pair under consideration is considered a pair of parallel documents. Based on the “nature” of the documents and the effectiveness of Bitextor, it is very likely that the resulting pairs consist of parallel documents.

4.1 Acquired Parallel Corpora

In order to examine the effectiveness of the modified workflow in acquiring parallel data from the web, we used it for constructing parallel corpora for the English-Greek language pair, in two domains (“Environment” and “Labour Legislation” as a wide and a narrow one, respectively). Table 3 illustrates the amount of data collected by using the proposed method.

Since the identification of web domains containing pages in the targeted languages and relevant to the selected domains is a time-consuming task and was done manually, only a few web domains were found to be crawled. However, the amount of acquired data was a good start for adapting an SMT system in these domains. In fact, training a baseline SMT system with the collected in-domain data improved the translation quality as reported in (Pecina et al., 2011).

	ENV	LAB
# of web domains	6	4
# of document pairs	147	126
# of tokens	17,033	13,169

Table 3 Quantitative information for acquired parallel data.

5. Conclusions and Perspectives

We have presented a method for acquiring comparable and parallel corpora from the web. Each module of the proposed workflow is detailed in both cases. The components (i.e. FMC and FBC) that have been implemented for these tasks are available as web services at <http://nlp.ilsp.gr/soaplab2-axis/>. By employing these tools, we collected documents in three domains for the English-Greek language pair. Although one of the targeted languages is less-resourced (i.e. Greek), the amount of acquired resources might be a useful collection for extracting a sufficient number of parallel sentences to train/adapt/test an SMT system. In order to verify this assumption, we aim to examine the collected resources and calculate the number of translation equivalents that could be extracted. A next step will be the evaluation of an SMT system adapted to the selected domains by using the web-crawled data.

Future work also concerns the enhancement of each module applied on each separate task. For example, we plan to combine the text-to-topic classifier with the cleaning tool in order to identify parts of texts which are in general domain and discard them.

L2 GREEK DETERMINER SYSTEM: EVIDENCE FROM TURKISH ADULT LEARNERS

Vasiliki Mavridou

Democritus University of Thrace, Greece

vicky_mav77@yahoo.com

ABSTRACT

This study investigates the status of determiners in L2 Greek of Turkish adult learners in view of the 'Interpretability Hypothesis' (Tsimplici 2003, Tsimplici & Dimitrakopoulou 2007). This hypothesis argues that L2 uninterpretable features, when unavailable in L1, are inaccessible to the L2 learner even in advanced L2 development. Our assumption is that mismatching parametric values between Greek and Turkish with respect to (un)interpretable features on determiners might cause learnability problems. Four groups of learners at different proficiency levels were tested. The results indicate that learners could dissociate different article environments and that optionality in article use is not a permanent problem.

1. INTRODUCTION

1.1 Interpretability Theory in L2 grammars

Our analysis is based on the Minimalist Program (Chomsky, 1995, 2005) and on recent theory of L2 development upon the way LF-interpretable and uninterpretable features affect learnability (Tsimplici 2003; Tsimplici & Mastropavlou 2008). Proposals of L2 development (hereon L2A) based on interpretability in correlation with the age factor argue that, if L1 and L2 differ in the values of a particular set of parameters in terms of interpretable and uninterpretable features, or if this set of parameters is absent (not grammaticalised) in the L1, the uninterpretable features will give rise to different developmental patterns even in advanced stages of L2A. This is a version of the 'no access to UG' hypothesis and of the Failed Functional Features Hypothesis (Hawkins & Chan, 1997; Smith & Tsimplici, 1995; Tsimplici & Roussou 1991), namely the Interpretability Hypothesis (Tsimplici 2003; Tsimplici & Dimitrakopoulou 2007). Contrary to 'full access to UG' L2A theories (Lardiere, 1998, 2000; Schwartz & Sprouse, 1996; Haznedar & Schwartz 1997; Vainikka & Young-Scholten, 1996; White, 1989, 2003; a. o.), the Interpretability Hypothesis argues for no access to language particular L2 properties and predicts persistent problems for the L2 learner with respect to L2 parametric values that differ from his L1. And although this is assumed to be the case even in post-critical age L2A, prolonged exposure to L2 input is assumed to lead to progressive targetlike performance. Additionally, given the unavailability of functional features, L2 behaviour is argued to show transfer of L1 parametric values (Tsimplici 1997), optionality/ variability in the use of L2 morphosyntactic elements and also misanalysis of the L2 input, that is, non-target feature specification in terms of production of representations that would diverge both from the L2 native speaker and their L1s (Tsimplici & Mastropavlou 2008).

The present study attempts to provide further evidence for the Interpretability Hypothesis on the basis of L2 behavior in Greek determiners. More specifically, this paper investigates the Greek article system in Turkish adult speakers by focusing on definite and indefinite DPs. With respect to the L2A of D elements in Greek L2, it is assumed that there should be a distinct pattern of development differentiating the definite from the indefinite article, in which pattern the definite article would be more problematic for L2 learners than the indefinite. Our assumption is based on the fact that, Turkish, being the speakers' L1, has mismatching parametric values with Greek with respect to the features of definiteness and specificity on determiners, and this might cause learnability problems. More clearly, it is argued that the specification of LF-interpretable feature of [-definiteness] on the indefinite article, and absence thereof on the definite article, gives rise to a different learnability pattern in Greek L2 grammars. Finally, it is questioned whether the inaccessibility of uninterpretable features leads to a

misanalysis of the definite article in advanced L2 grammars or gives evidence of real variability/optionality in use.

1.2 Features of the learners' L2 (Greek)

Greek is a language with a morphologically rich determiner system, including a definite and an indefinite article, which inflect for case, number and gender. Agreement is always required between the noun (N), any adjectives appearing in the DP and the determiner (D), as shown below:

DEFINITE NP	INDEFINITE NP
O psilos tixos.	Enas psilos tixos.
the-masc.sing.nom high-masc.sing.nom wall-masc.sing.nom	One-masc.sing.nom high-masc.sing.nom wall-masc.sing.nom
'the high wall'	'a high wall'

Table 1 Agreement in definite and indefinite NPs

The morphological paradigm showing formal features (number, gender, case) on Greek articles is presented in Table 2:

	DEFINITE ARTICLE						INDEFINITE ARTICLE					
	MASC.		FEM.		NEUT.		MASC.		FEM.		NEUT.	
CASE	SING.	PL.	SING.	PL.	SING.	PL.	SING.	PL.	SING.	PL.	SING.	PL.
NOM.	o	i	i	i	to	ta	enas	-	mia	-	ena	-
GEN.	tu	ton	tis	ton	tou	ton	enos	-	mias	-	enos	-
ACC.	to(n)	tus	ti(n)	tis	to	ta	ena(n)	-	mia	-	ena	-

Table 2 The definite and the indefinite articles in Greek

There are also cases where zero article (Clairis, Babiniotis 2005) must be used, i.e. no article is needed. Absence of the article in such cases is not considered as omission. Rather, it serves a specific function, that of generic reference. The sentences below illustrate zero, definite and indefinite article use in association to the function served and Table 3 summarizes the referential status of every article type:

- (i) Ipiame Ø krasi ke faghame Ø kreas. – generic reference
'We drank wine and ate meat.'
- (ii) Ipiame to krasi ke faghame to kreas. – specific reference
'We drank the wine and ate the meat.'
- (iii) Ipiame ena krasi ke faghame ena kreas. – un-specific reference
'We drank some wine and ate some meat.'

	REFERENCE		
ARTICLE TYPE	Generic	Specific	Non specific
Definite article	YES	YES	NO
Indefinite article	YES	NO	YES
Zero article	YES	NO	YES

Table 3 The referential status of Greek articles

Moving to an analysis of Greek articles in Minimalist terms, the analysis proposed by Tsimplici and Stavrakaki (1999) is adopted. It has been argued that the definite article differs from the indefinite one in terms of feature-specification, in that, while the definite article hosts uninterpretable features only (case and *phi*-features), the indefinite article is also intrinsically specified/marked for the interpretable feature of [-definiteness] (Karanassios 1992, Tsimplici and Stavrakaki 1999). Table 4 summarizes the properties of articles in Greek based on their respective feature-specification:

Articles	Interpretable features	Uninterpretable features
Definite article	Ø	[case], [agreement]
Indefinite article	[-definite]	[case], [agreement]

Table 4 Properties of articles in Greek

1.3 Features of the learners' L1 (Turkish)

Coming to Turkish, it is argued to lack a D system in that it does not have a determiner system distinguishing between definite and indefinite articles (Kornfilt 1997). In Turkish, specificity and definiteness depend on other factors, such as case, word order, stress and modality (Göksel & Kerslake 2005, Enç 1991, Kornfilt 1997), as shown in the examples below:

CASE

- (i) Aylin şapka sevir. ('Aylin loves hats.') – non-specific reference
hat-NOM
- (ii) Aylin şapkayı sevir. ('Aylin loves the hat.') – specific reference
hat-ACC

WORD ORDER

- (i) Pencereden hırsız kaçmış. ('A burglar/ Burglars escaped from the window.') - non-specific
- (ii) Hırsız pencereden kaçmış. ('The burglar escaped from the window.') - specific

STRESS

- (i) MektupLAR imzalandı. 'Letters were signed.' – non-specific
- (ii) Mektuplar imzalanDI. 'The letters were signed.' – specific

MODALITY

- (i) Bebek süt iç^{er}.
drink-AOR
'Babies drink milk.'/ 'A baby drinks milk.' - generic
'The baby drinks milk.' - non-specific
- (ii) Bebek süt iç^{iyor}.
drink-PROG
'The baby is drinking (some) milk.' - specific
'The baby drinks milk.' - specific

2. PREDICTIONS

As pointed out earlier, this study aims to investigate the L2A of the Greek article system by Turkish native adult learners and our assumptions are based on the Interpretability hypothesis put forward in Section 1. On the basis of (i) the relationship between feature-interpretability and learnability, (ii) the uninterpretable features on the Greek definite article, and (iii) the absence a definite article in the learners' L1, i.e. Turkish, the following predictions are made:

- 1) Definite article omissions in obligatory contexts are expected due to L1 transfer.
- 2) Indefinite article omissions in obligatory contexts are expected to be less than definite article omissions in the respective definite contexts due to the role of interpretability in developing L2 grammars.
- 3) A distinct pattern of development differentiating the two articles, the definite being more problematic for L2 learners than the indefinite, is expected.
- 4) Zero article contexts are expected to be nativelike due to L1 transfer.
- 5) In interchangeable i) definite/ indefinite/ zero article, ii) definite/ zero article and iii) indefinite/zero article contexts, higher rates of zero article use are expected due to L1 transfer.
- 6) In interchangeable definite/ indefinite article contexts, preference to the indefinite article is expected.
- 7) Correct use of all articles is expected to increase with proficiency but not reach nativelike levels due to age constraints.

3. THE STUDY

3.1 Participants

Our data come from forty native Turkish speakers who volunteered to take part in the study. All speakers were, at the time, university students learning Greek as L2 in the Department of Modern Greek Studies in the Istanbul University of Istanbul. No student had any previous knowledge of Greek before entering the specific university, in which both Greek and Turkish are used as means of instruction. For the purposes of our research, the subjects are divided into four groups according to their year of studies (assumed as L2 Greek proficiency level), as is depicted in Table 5:

Subjects (N=40)	L2 Proficiency level
Group 1 (N=13): 1 st year students	1
Group 2 (N=10): 2 nd year students	2
Group 3 (N=3): 3 rd year students	3
Group 4 (N=14): 4 th year students	4

Table 5 Classification of the subjects in terms of L2 proficiency

3.2 Tasks

Data was collected in the period of April–May 2010 and come from spoken production in the form of one-to-one interviews, which were tape-recorded and transcribed by means of the CHILDES program. The interviews consisted of three parts: i) filling-in of and discussion upon a personal questionnaire regarding biographical details relevant to the subjects' exposure to L2, ii) story-telling by means of descriptions of sets of pictures each forming a story that the student had to narrate. Each participant was asked to describe two sets of pictures upon a random selection from a group of eight sets, iii) isolated picture description upon random selection of 12 out of 36 pictures. The interviews lasted 10-15 minutes, depending on the fluency of the participants.

Our study focuses on the errors observed in the spoken production of the Turkish learners with regard to their use of the Greek definite, indefinite and zero articles. Errors are based on obligatory and interchangeable contexts. Thus, a classification of the contexts on which our research was based is shown below:

- i) definite article obligatory contexts
- ii) indefinite article obligatory contexts
- iii) zero article obligatory contexts
- iv) definite, indefinite and zero article interchangeable contexts
- v) definite and zero article interchangeable contexts
- vi) indefinite and zero article interchangeable contexts
- vii) definite and indefinite article interchangeable contexts.

Errors are classified according to one of the three types: i) omission, ii) substitution and iii) overgeneralization. Results are then analyzed comparatively for all groups. The examples below¹ taken from our data illustrate how the learners i) failed to supply the article required (i.e. omission errors), ii) incorrectly substituted one article for another in obligatory contexts (i.e. substitution errors), or iii) overgeneralized one article type in zero article contexts (i.e. overgeneralization errors):

(i) OMISSION ERRORS

a. definite article omission

S1: *(o) idhjos adras ke *(i) ghineka ine sto estiatorio.
 (the) same man and (the) woman are in-the restaurant
 "The same man and the woman are in the restaurant."

(i) b. indefinite article omission

S22: Afti stelni *Ø dhorο *tin mama

¹ Asterisks show problematic contexts, whereas the items in parentheses are not produced by the L2 speaker.

She sends – gift the mum
 “She sends (a) gift (to) (her) mum .”
Correct: Afti stelni ena dhoro stin mama tis.
 she sends a gift to+the mum her
 “She sends a gift to her mum.”

(ii) SUBSTITUTION ERRORS

a. definite article substitution (and omission)

S2: ... stelno *Ø ghrama *ena baba su ke *Ø mama su.
 Send - letter *a dad your and - mum your
Correct: ...stelno (to) ghrama (ston) baba su ke (stin) mama su
 send (the) letter (to-your) daddy and (to-your) mummy
 “I send the letter to your daddy and mummy.”

b. indefinite article substitution

S25: mia ghineka ke *o adras ine mesa (s)to treno.
 a woman and the man are in the train
 “A woman and *the man are in the train.”
Correct: mia ghineka ke enas adras ine mesa sto treno
 a woman and a man are in the train
 “A woman and a man are in the train.”

(iii) OVERGENERALISATION ERRORS

a. overgeneralization of definite article in zero article context

S25: Pai *(se) ena katastima *ton paputsion
 goes to a store of-the shoes
 “He goes to a store of *the shoes”.
Correct: pai se ena katastima Ø paputsion
 goes to a store shoes
 “He goes to a shoe store.”

b. overgeneralization of indefinite article

S2: edho exi *ena pedhja.
 here there-are *a children
 “Here there are *a children.”
Correct: edho exi Ø pedhja.
 here there-are children
 “There are children here.”

(iv) INTERCHANGEABLE CONTEXTS

a. definite/ indefinite article and zero/ definite/ indefinite article interchangeable contexts

o/enas adras pini Ø /ton/ena kafe.
 The/a man drink-3rd.sing Ø /the/a coffee
 “A/The man drinks -/the/a coffee.”

b. zero/ definite/ indefinite article interchangeable context

Aftos dhjavazi Ø/ tin/ mia efimeridha
 He reads Ø /the/a newspaper
 “He is reading -/the/a newspaper.”

4. THE RESULTS - DISCUSSION

In what follows, the results from our research are presented in discussion with the predictions made in Section 2. The results were based on the total number of obligatory and interchangeable contexts for every group of students (see Table 6). Error analysis followed each type of context and statistical analysis was computed to assess the relationship between the groups of students (i.e. year of study/ proficiency level) and their performance.

Subjects	Total NPs	Obligatory contexts			Interchangeable contexts
		Def. art NPs	Indef. art NPs	Zero art. NPs	
1 st year	550	162	63	70	255
2 nd year	368	128	27	40	173
3 rd year	172	45	12	33	82
4 th year	458	166	38	52	202
TOTAL	1548	501 (32,4%)	140 (9%)	195 (12,6%)	712 (46%)

Table 6 Definite, Indefinite, Zero article obligatory and interchangeable contexts

With regard to Prediction 1, according to which definite article omissions in obligatory contexts are assumed to be expected due to L1 transfer, we notice high rates of correct use for all groups (see Figure 1), what accounts for learnability of the definite article to a great extent. The results are significant for all groups at the 0.05 level ($F=14,399^a$, $p<.002$) and there is positive correlation between the groups and their performance (Pearson's $r=0.099$, $p=0.026$).

Figure 1 Definite article correct use and error rates in obligatory contexts

Error analysis in the above contexts (see Figure 2) reveals definite article omissions in all groups, which makes Prediction 1 to be confirmed. The results are significant for all groups ($F=29,071$, $p<.000$) and there is positive correlation between the year of study and the errors made in definite article contexts (Pearson's $r=0,198$, $p<.031$).

Figure 2 Error analysis in definite article obligatory contexts

Moving to Predictions 2 and 3, we check, first, whether indefinite article omissions are less than definite article ones or not in respective obligatory contexts (Prediction 2), and secondly, whether a distinct pattern of development that differentiates the definite from the indefinite article takes place or not (Prediction 3). Figure 3 below shows that in indefinite article obligatory contexts performance of all groups -with the exception of the 3rd - is slightly better compared to definite contexts, what is in line with our expectations. The results are significant for all groups ($F= 17,182^a$, $p<001$). Moreover the year of study and performance in definite / indefinite article correct use are strongly related and dependent (Pearson's $r = -0,77$, $p < .035$).

Figure 3 Correct use of definite and indefinite articles in obligatory contexts

With respect to errors (see Figure 4), the results confirm Prediction 2, since all groups omitted definite articles very frequently, whereas indefinite article omissions are observed only in beginners. Therefore, in indefinite contexts native-like performance seems to be achieved with proficiency, what was not the case in definite ones.

Figure 4 Error analysis in definite and indefinite article obligatory contexts

The results also show that a distinct pattern of development separating the two articles takes place and as such, Prediction 3 is confirmed. However, despite the slight divergence existing in the

development of the two articles, the fact that both are used correctly to a great extent in obligatory contexts shows that definite article development is not that problematic compared to that of the indefinite. Thus, it can be assumed that L2 learners seem to be able to assign the feature of definiteness, existing in their L1, at advanced stages of L2 development. The results are very significant for all groups ($F=46,696^a$, $p<.000$).

Moving to Prediction 4, we should check what the case is in zero article obligatory contexts and whether performance in these contexts is nativelike due to L1 transfer or not. Data from these contexts reveal almost targetlike behaviour for all groups (95%), which goes along to our expectations. Statistical analysis however revealed that the relation between the groups of students (i.e. year of study/ proficiency level) and their performance in these interchangeable contexts is not very strong and the results are not significant, since the correlation coefficient is not very highly significantly different from zero (Pearson's $r=0.062$, $p<0.388$).

At first glance, L1 transfer could account for these results, since Turkish is an articleless language. However, error analysis in these contexts shows overgeneralization of definite (89%) rather than the indefinite (11%) article, which makes L1 transfer accounts sound problematic. Assuming that L1 transfer does play a role in L2A, then it would be expected that students would overgeneralize the indefinite rather than the definite article in these contexts, since in Turkish, lacking itself an indefinite article, the numeral *bir* 'one' is used instead.

Turning now to a discussion of the results in interchangeable contexts (Predictions 5 and 6), we will examine which article students prefer in contexts where one article or the other could be used interchangeably without meaning effects. Figures 5 to 8 below depict schematically the results for all types of interchangeable contexts.

i) Starting with definite/ indefinite/ zero article interchangeable contexts (Figure 5), the results confirm our predictions, since all groups tend to prefer the zero article. Second comes preference to the definite article, although we would expect students to cline to indefinite article use, based both on the feature specification of the two articles in Greek and on the fact that Turkish, as mentioned before, uses the numeral *bir* as an indefinite article. Statistical analysis revealed that the strength of association between the groups of students and their performance in these contexts is not very high and the results are not significant (Pearson's $r=0.041$, $p<0.747$).

Figure 5 Article distribution in definite/ indefinite/ zero article interchangeable contexts

ii) In interchangeable definite/ zero article contexts (see Figure 6), the results show students' preference to zero article use, not unexpectedly. Both feature-specification and L1 transfer account for the results, although the latter can only partly do so, because there is great intergroup variation. Quite unexpectedly, 2nd year students seem to prefer definite article use and 4th year students show clear optionality in zero and definite article use. This gives precedence to the view that a misanalysis of the definite article does occur in advanced L2 grammars and that L2 learners assign the feature of definiteness (existing in their L1 grammars) to L2 parametric features non-existing in their L1. Statistical analysis revealed that the relationship between the two variables (year of study and

performance in definite/ zero article interchangeable contexts) is not very strong and the results are not significant (Pearson's $r = 0.063$, $p < 0.615$).

Figure 6 Article distribution in definite/ zero article interchangeable contexts

iii) Article distribution in contexts where indefinite and zero article can be used interchangeably (see Figure 7) shows that all groups tend to show preference to zero article use, what goes along with our predictions. Again the relationship between the groups of students and their performance in indefinite/ zero article interchangeable contexts is not very strong and the results are not significant (Pearson's $r = 0.041$, $p < 0.725$).

Figure 7 Article distribution in indefinite/ zero article interchangeable contexts

iv) In definite/ indefinite article interchangeable contexts (see Figure 8), most learners tend to use the indefinite rather than the definite article, which is also in line with our expectations. What is also common for all groups in these contexts, is the fact that they all show article omissions (see zero article rates), assumedly, due to L1 transfer. Statistically speaking, the results are not significant (Pearson's $r = 0.005$, $p < 0.932$).

Figure 8 Article distribution in definite/ indefinite article interchangeable contexts

Closing our discussion with Prediction 7 (see Figure 9), it has been assumed that correct use of all articles would increase with proficiency but not reach nativelike levels, due to age constraints. As expected, article use in L2 Greek seems to somehow develop in correlation to L2 proficiency and, as such, Prediction 7 is largely confirmed. Data show that 4th year students outperform all other groups in all article contexts -with the exception of the definite ones, where 2nd year students perform slightly better-. Results also reveal that, with the exception of the 3rd group, proficiency-based development is clearer in definite and indefinite article contexts, whereas in zero article contexts all groups behave almost targetlike. More specifically, definite article development seems to be later compared to that of the indefinite, which in turn is later than that of the zero article. Thus, whereas nativelike performance seems to take place only for the zero and the indefinite articles in general, we can assume that prolonged exposure to input seems to lead to successful production even for the definite article.

Figure 9 Development with proficiency in definite, indefinite and zero article obligatory contexts

The first reason to account for this non-native behavior in definite article development is non-target feature-specification of determiners in the L2. A second reason is the age factor. However, we would

expect the development taking place to be even more minimal in degree, since all participants were adult L2 learners who, having exceeded critical age for L2A, are supposed to have reached a steady state in the development of certain L2 parameters non-existing in their L1. This goes along with L2A theory which argues that uninterpretable features are subject to critical period constraints and therefore inaccessible to L2 learners, whereas interpretable features are always accessible (Tsimpili 2003). If this hypothesis is correct, then we would expect indefinite article use to be by far targetlike and definite article use to be problematic due to its non-target feature-specification in the L2 lexicon. Contrary to our assumptions, in this study the definite article appears to somehow develop even in adult L2 grammars. We can thus assume that, in many respects, our learners can impose interpretable features such as [referentiality] or [specificity], existing in their L1, on the Greek article and that, as such, L2 use resists age constraints but does not become nativelike.

5. CONCLUSIONS - IMPLICATIONS

The discussion in this paper is based on the interpretability distinction on articles in L2 Greek. It has been argued that the definite and the indefinite articles should pattern differently, since they are differently specified in terms of interpretability, in that, whereas the former is not inherently specified for definiteness, the latter is intrinsically marked as [- definite]. Our data come from four groups of adult L2 learners with diverse L2 proficiency levels. The learnability theory we follow suggests that all groups should show evidence for differential performance in interpretable versus uninterpretable features on the grounds that the latter are difficult to access in any developmental process other than normal L1 development.

The study yielded several findings concerning L2A of Greek articles. With respect to obligatory contexts, the findings suggest that all groups of learners were able to dissociate different article environments by supplying the required article at a higher rate than other articles. Thus, learners seem to have an understanding of the Greek article system and attempt to use articles correctly instead of using them randomly.

Moreover, our learners show some predicted differences in article use. With respect to the definite article, although no group performs targetlike, results show that prolonged exposure to input can lead to successful production in non-natural contexts. Coming to the indefinite article, our Turkish learners seem to be able to distinguish indefinite earlier than definite contexts, since performance in the former is comparatively better than in the latter. Thus, although there is evidence for acquisition of both articles, that of the definite seems to be somehow more delayed. Delayed and problematic behavior in definite article use is argued to stem both from L1 transfer and inaccessibility of uninterpretable features. However, results show proficiency-based development for all articles, which suggests, on the one hand, that even the definite article can be sufficiently acquired with proficiency and as such, uninterpretable features are accessible to the advanced L2 grammar, and on the second, that becoming more proficient helped learners eliminate potential L1 effects. As for optionality in article use, some fluctuation between the definite and the indefinite article in obligatory contexts is observed even in advanced groups.

With respect to interchangeable contexts, that is, cases where one article or the other could be used interchangeably in the same context with no communication effect, results, although interesting, are not significant based on the statistical analysis and thus generalisations are not to be made. Analytically, in all such contexts where zero article use could be an option, all groups of learners show preference to zero article, not unexpectedly. On the other hand, in definite/ indefinite article interchangeable contexts, L2 learners seem to fluctuate between the two articles showing some preference to the indefinite rather than the definite article.

To sum up, in line with what was supported in previous L2 research, the learners of this study are able to distinguish between [+/- definite] features that govern the article use in L2 Greek despite the absence of an article system in L1 Turkish. In addition, although the learners' accuracy in the use of articles increased with L2 proficiency, perfect mastery of the Greek article system does not seem to be an easy case for them. Our conclusions suggest that learners' variable performance does not reflect a potential underlying grammar deficit. Rather, they seem to misanalyze the Greek definite article as an element bearing a specificity feature in order to partly regulate its distribution.

Abstract

A longitudinal case study involving three successful language learners, (1 bilingual boy, 1 bilingual girl and 1 monolingual girl) was conducted in order to observe how language learning strategies develop across languages and whether bilingual learners' use of strategies differs quantitatively and qualitatively from that of monolinguals when learning English L3. The study also investigated the effect of the bilingual learners' gender on strategy use. The data was collected through combined research methods: the SILL questionnaire (Oxford, 1990), the LSUI inventory (Cohen, Oxford & Chi, 2006), semi-structured interviews, verbal reports (Cohen, 1996) and task product analysis (Bialystok, 1990a; Abraham & Vann, 1996). From the results of the study it can be stated that the bilingual learners used more strategies more frequently than the monolingual one. Differences were also observed in strategy use between the male and female bilingual learner with the female using overall more strategies. As for the quality of strategy use, our findings suggest that the bilinguals showed willingness to take risk and practice naturalistically and have the necessary tools to foster and promote autonomy beyond the classroom and the teacher's control.

Keywords: case study, monolingual, multilingual, language learning strategies, SILL, cross-linguistic

1. Introduction

The last decade has seen a significant amount of research into multilingualism and third language acquisition (De Angelis, 2007; Aronin & Hufeisen, eds., 2009; Cenoz, 2009, etc.). Various models of multilingualism acknowledge the importance of language learning strategy development and use (e.g., Herdina & Jessner, 2002), yet there is very little evidence of how language learning strategies influence third language learning and what their role in cross-linguistic influence among L1, L2 and L3 is. This paper focuses on the study of language learning strategy development and use of three learners of English. The participants were tutored by one of the researchers for three years and successfully completed their B2 and C2 level international English examinations. They were 1 bilingual boy aged 10-13, with L1 Greek and L2 Serbian, 1 bilingual girl aged 12-15, with L1 Russian and L2 Greek, and a control participant, 1 monolingual girl aged 11-14 with L1 Greek, all of whom received tutorials individually, for 3 hours a week over a period of 3 years. It was noticed that the two bilingual learners used a different approach to third language learning from numerous monolingual learners the researchers had taught and that there were striking similarities between the two of them. Thus, a systematic observation was set up consisting of combined methods of research with the aim to identify the possible differences in language learning strategy use and speculate on the causes.

2. Literature review

Our study explores two areas that have been gaining popularity in foreign language research: language learning strategies (LLS) and multilingualism.

Although the concept of ‘language learning strategies’ is not easily definable, listing their essential features allows comparability across studies and gives results a greater explanatory power. According to recent research (Cohen, 2005, Griffiths 2008, Oxford 1990, 2011) the main characteristics of LLS are the following. First of all, they are mental activities which serve the completion of a certain goal. They are also used to regulate learning and form strategy clusters which are evaluated via a series of metacognitive strategies. Strategies also include a socioaffective aspect, they are chosen by learners themselves and can contribute to the promotion of successful learning. Finally, they can be taught and can help teachers expand their role in class.

In general, it is agreed that the use of LLS is positively related to language proficiency overall or in specific skills. Research has shown that successful language learners use more strategies more frequently than students with lower proficiency (Griffiths 2003, Lan & Oxford 2003, Psaltou & Kantaridou, 2009). What differentiates higher proficiency students is also the metacognitive knowledge to opt for appropriate strategies and use them in an orchestrated fashion that meets both the task demands and their own learning strengths (Cohen & Macaro, 2007). Therefore the difference in strategy use, as far as proficiency is concerned, is both quantitative and qualitative.

As for the role gender plays in strategy use, most findings confirm the existence of significant gender differences, with females reporting using overall more strategies than male learners (Green & Oxford 1995, Dreyer & Oxford 1996, Peacock & Ho 2003, Gavrilidou & Papanis 2009).

For a long time multilinguals were viewed as the sum of two or more monolinguals and their linguistic knowledge of two or more languages was strictly measured against the language proficiency of monolinguals in each of these languages. Eventually, this view changed and multilingualism is now viewed as a complex phenomenon (Herdina & Jessner, 2002; Cenoz, 2003; Aronin & Hufeisen, 2009, etc.). It must be admitted that although bilingualism and multilingualism share many important features, third language acquisition is different from second language acquisition in that it is not only L1 that influences L2 acquisition but vice versa, and similarly L3 can influence L2 and L1. Generally, cross-linguistic influence in multilinguals is far more complex and diverse. The advantage of a bilingual over a monolingual learner has been stressed by researchers as bilinguals already have access to two language systems and are generally aware of the processes involved in acquiring a language and can draw from that experience. However, they may be at a disadvantage as well because of phenomena such as code mixing or attrition. It could also be assumed that bilinguals follow a different route and learn L3 in a different way than monolinguals. (Cenoz, 2009)

There are findings that show that multilinguals are more flexible when switching strategies depending on task demands or in case of ineffective learning and are better at using implicit rather than explicit learning strategies. Bono and Stratilaki (2009) also point out that bilinguals learning L3 possess a complex set of metalinguistic knowledge, strategies and beliefs which differentiate them not only quantitatively but also qualitatively from monolingual learners. In Greece, Psaltou-Joycey and Kandaridou (2009) conducted a study on plurilingualism (individual multilingualism), language learning strategy use and learning style preferences and concluded that trilingual students use more strategies, more frequently than bilingual students and that their learning styles differ as well.

Finally, it is significant to refer to the different aims and methodologies used in the research in third language acquisition. As Canoz (2003) points out, some of these studies are concerned with general language development by multilinguals while others study specific aspects of the process. She stresses the need to further examine specific characteristics of third language acquisition as is the case in the present study where bilinguals’ language learning strategies are recorded and analyzed against those of monolinguals.

3. Case study background

This is a participant-observation study of three early adolescents who received English language tutorials by one of the researchers for three years as part of preparation for B2 and C2 level exams. The first observation began in 2008 and involved the first participant, a 10 year old boy who at that time was bilingual in Greek and Serbian and had been learning English formally for 5 years. He can be described as an ambilingual balanced bilingual who started using both Greek and Serbian at the same time being exposed to both languages from birth. Greek was the language of the host country and his father’s native language while Serbian was his mother’s first language and the language he used during

his visits to Serbia. Both his parents are English teachers who switched codes regularly between English, Greek and Serbian in every day conversations that he took part in as well. He is literate in all three languages, although to a lower degree in Serbian than Greek or English. He received formal education in Greek while English was taught as a school subject and Serbian informally at home by the mother.

The second participant, the bilingual girl aged 12-15, started her English tutorials at about the same time and it became apparent that the two of them shared some common learner characteristics. The girl came from an immigrant expatriated family from Russia who had come to Greece when she was an infant. She only spoke Russian till the age of six when she started school and had to attend classes in Greek. So, based on the order of acquisition she can be described as a non-ambilingual balanced bilingual who has the same level of proficiency in both Greek and Russian but not the same level of literacy, as she does not use Russian to read or write so often. She received English lessons as part of formal education at school and private lessons to prepare for her examinations. At home, she mainly speaks Russian with her family while she speaks Greek with her friends.

The third participant was selected as a control one to verify the assumptions on whether or not bilinguals develop different learning strategies when learning a third language than monolinguals that learn a second language. She was a monolingual girl aged 11-14 with L1 Greek who also received tutorials in English for three years and successfully passed her B2 and C2 examinations. She was taught English in school but also had had private lessons by a native English speaker for a period of 6 years prior to the observation period.

4. Research hypotheses

The research hypotheses posed in this study were the following:

*Bilingual learners use more strategies more frequently than monolinguals when learning a L3.
Bilingual learners' use of strategies differs qualitatively from that of monolinguals when learning English L3.*

Bilingual female learners use more strategies more frequently than bilingual male learners.

4.1. Research methodology

Instruments used in the collection of data from the three learners were:

(1) The "Strategy Inventory for Language Learning" (SILL) questionnaire (version 7.0 – ESL/EFL) developed by Rebecca Oxford (1990: 293-300) including six different strategy categories: memory, cognitive, compensation, metacognitive, affective and social which has 50 items corresponding more or less to a specific strategy. These items are rated on a 5-point Likert scale, ranging from 'never or almost never true of me' to 'always or almost always true for me'. This inventory provides information about a) overall frequency of strategy use and b) preferred individual strategies in each of the six categories. According to research reports, the SILL appears to be the only LLS instrument that has been extensively checked for reliability (in general the SILL reliabilities have been high) and validated in multiple ways. It can also be used to examine the frequency of strategy use in relation to factors such as gender, age, cultural background, etc. The SILL was administered at the beginning of the observation and after three years.

(2) The "Language Strategy Use Inventory" (LSUI), developed by Cohen, Oxford and Chi (2006). Strategies are classified according to skill area (listening, reading, speaking and writing) and categories associated with vocabulary and translation strategies. The questionnaire contains 90 items selected on the basis of a 4-point scale: 1) I use this strategy and I like it, 2) I have tried this strategy and would use it again, 3) have never used this strategy but I'm interested in it, 4) this strategy doesn't fit me. Learners make a qualitative evaluation of their strategy use thinking about the outcomes of strategy use. It is worth mentioning that this inventory does not provide a score on strategy use for a given skill or language overall. According to its designers, it avoids purposely having learners rate the strategies by frequency of use because the reason you use a strategy a lot is because you need to use it a lot to make it work. The strategies that were selected to monitor the three learners' strategy use were specific strategies involved in a particular skill area, such as listening, speaking, reading, writing, vocabulary and grammar and they covered numerous categories. The categorization was based on Oxford's six categories of direct and indirect strategies.

(3) Proficiency tests to determine the progress in language learning covering all four skills and to insure that the three participants did not differ from one another with respect to the level of proficiency. The proficiency tests used consisted of B2 level tests during year 1, C1 level tests during year 2 and C2 level tests during year 3. They were KPG past exam papers for B2 and C1 level and Michigan University past exam papers for B2 and C2 level. The learners were continually tested in all four skills and their progress was measured.

(4) Semi-structured interviews. The interview questions included think-aloud protocol questions which helped establish the processes happening during and after task completion in all four skills and vocabulary and grammar tasks. The learners' answers were recorded and transcribed. For example, during a completion of a written task the participants were asked to describe the thinking processes relevant to the task planning, execution, evaluation and repair. At the same time, the researcher would prompt the participants about the way they gathered information, developed ideas organized their writing, used dictionaries, wrote drafts, etc. Similar procedures were applied to other types of tasks. The participants were also asked to self-evaluate their learning and using of languages in general.

These strategy assessment measures were chosen because they combine a quantitative and a qualitative evaluation of the specific learners' strategy use thus allowing the researchers to assess it in a more consistent way and provide triangulation of the findings.

5. Results

Before presenting the findings, it is necessary to clarify that the results in general were considered and characterized according to their possible significance in percentages and not statistically speaking, due to the small sample of the participants. The exceptions are the following findings resulting from the statistical analysis of the SILL scores at time 1 and time 2 for all three cases using SPSS v19.

	Mean	N	Std. Deviation	Std. Error Mean
time1	2,9267	3	,48429	,27960
time2	3,2867	3	,65858	,38023

Table 1 Descriptive statistics showing the overall mean scores on the SILL for all three cases at time 1 and time 2

	Mean	Std. Deviation	Std. Error Mean	t	df	Sig. (2-tailed)
time1 - time2	-,36000	,17436	,10066	-3,576	2	,070

Table 2 The results of t-test (sig=0,070>0,05) showing that there are no statistically significant differences between the two measurements for all three cases with respect to the mean scores on the SILL

		Mean	N	Std. Deviation	Std. Error Mean
Pair 1	Memory time1	2,3333	3	,90948	,52509
	Memory time2	2,5185	3	,95796	,55308
Pair 2	Cognitive time1	3,4524	3	,36654	,21162
	Cognitive time2	3,8095	3	,55482	,32032
Pair 3	Compensation time1	3,5000	3	,88192	,50918
	Compensation time2	3,6111	3	,85527	,49379
Pair 4	Metacognitive time1	2,8889	3	,77778	,44905
	Metacognitive time2	3,5185	3	1,02640	,59259
Pair 5	Affective time1	2,2778	3	,58531	,33793
	Affective time2	2,5556	3	,76980	,44444

Pair 6	Social time1	2,7222	3	,85527	,49379
	Social time2	3,2778	3	1,05848	,61111

Table 3: Paired Samples Statistics showing mean scores for each of the six strategy categories on the SILL at time 1 and time 2 for all three cases

The paired samples t- test was computed and it showed that there are statistically significant differences in the frequency of strategy use only in memory category between time 1 and time 2 for all three cases. (sig=0,038<0,05)

		Bilingual female		Bilingual male		Monolingual female	
		mean	%	mean	%	mean	%
Memory strategies	Time 1	3,3		2,1		1,5	
	Time 2	3,6	6.0	2,3	4.0	1,6	2.0
Cognitive strategies	Time 1	3,9		3,4		3,1	
	Time 2	4,4	10.0	3,6	4.0	3,4	6.0
Compensation strategies	Time 1	4,2		3,8		2,5	
	Time 2	4,3	2.0	3,8	0.0	2,6	2.0
Metacognitive strategies	Time 1	3,2		2,0		3,4	
	Time 2	4,1	18.0	2,3	6.0	4,1	14.0
Affective strategies	Time 1	2,3		2,8		1,6

	Time 2	4,5	16.0	2,7	14.0	2,6	2.0
Overall strategy use	Time 1	3,5	10.0	2,7	6.0	2,4	6.0
	Time 2	4,0	(70.0-80.0)*	3,0	(54.0-60.0)*	2,7	(48.0-54.0)*

* refers to the percentage of overall strategy use for time 1 and time 2

Table 4 Frequencies of learner responses to the SILL six categories and overall at time 1 and time 2 (mean ratings and differences between means for time 1 and time 2 in percentages)

All three learners improved the frequency of overall strategy use from time 1 to time 2. The bilingual girl's percentage increased from 70,0% to 80,0%, or 3,5 to 4,0 mean score (on a scale to 5), the bilingual boy's from 54,0% to 60,0%, or 2,7 to 3,0 mean score and monolingual girl's from 48,0% to 54,0%, or 2,7 to 3,0 mean score. It is evident that the two bilinguals improved the frequency of strategy use from time 1 to time 2 at a higher percentage and rate than the monolingual girl whose progress in strategy groups, such as memory, compensation, affective and social took place at a lower rate. The differences are more striking in memory, cognitive, compensation and affective categories of the SILL, except for the social strategies and metacognitive strategies where the monolingual girl exceeds the male bilingual. The most striking differences are observed in the memory, compensation and affective strategies (Table 4).

As for the memory strategies, both bilinguals reported to create mental linkages by connecting the sound of a new word and an image to remember the word, by using mental pictures of the situation

where the word might be used, by physically acting out words and by remembering its location visually. As for cognitive strategies, the bilinguals seem to resort more often to searching cognates in their L1 or L2, to trying to discover grammar rules by themselves, and to summarizing the information they hear or read. In the case of compensation strategies, both bilinguals use more often mime and gesture, make up new words and try to guess what the other person is going to say in a conversation. Finally, with respect to affective strategies they try to relax when using English and notice that they are nervous when using or studying English.

The LSUI results highlighted differences in the quality of strategy use between the bilinguals and the monolingual, as well (see Table 5). When asked to identify the strategies they regularly used and found suitable, the monolingual girl reported using 42 strategies (37,8%) out of 100 in total, the second was the bilingual boy with 38 strategies (34,2%) and the last was the bilingual girl with 33 strategies (29,7%). However, combined with the strategies that all three identified to have used and would use again yielded different results. Willingness to experiment and take risks with new strategies was highest in the bilingual girl (27 in number or 24,3%), than in the bilingual boy (18 in number or 16,2%) and only 5 in number or 4,5% in the monolingual girl. The bilinguals also reported interest in using strategies that were unfamiliar to them. The monolingual girl exceeded the bilinguals by 36,0% as opposed to 6,3% and 20,7% respectively concerning the number of strategies that she dismissed as unsuitable for her. Differences in the quality of strategy use are evident in listening, vocabulary and speaking skills in favor of the bilinguals, while the girls exceed the boy in writing.

	Bilingual female				Bilingual male				Monolingual female			
	1	2	3	4	1	2	3	4	1	2	3	4
	*	*	*	*	*	*	*	*	*	*	*	*
Listening	9	6	8	3	¹ ₃	7	3	3	¹ ₂	2	1	¹ ₁
Vocabulary	6	4	6	2	7	4	4	3	5	0	0	¹ ₃
Speaking	8	6	4	0	6	5	1	6	¹ ₀	0	0	8
Reading	6	5	0	1	5	2	2	3	7	1	1	3
Writing	4	3	3	0	4	0	1	5	7	0	0	3
Translation	0	3	2	1	3	0	0	3	1	2	1	2

Strategy categories:

1* I use this strategy and I like it.

2* I have tried this strategy and would use it again.

3* I have never used this strategy but I'm interested in it.

4* This strategy doesn't fit me.

Table 5 LSUI: Number and percentages of reported strategies for each of four strategy categories

As for specific strategies, there is a general overlap between the two bilingual participants. In the section on listening, they use strategies to become more familiar with the sounds of English by practicing very different sounds or by looking for aural associations. They use strategies that help them prepare for what is to follow in a conversation by paying special attention and they compensate for lack of knowledge by watching gestures or body language. They tend to use more strategies when they learn

vocabulary, while the monolingual participant relies on them to review, recall and use new words. In the speaking strategy group, the ones that stand out are the strategies employed to engage in conversations and to compensate for the lack of knowledge. The findings on this self-report questionnaire significantly match the ones on the SILL. When it comes to reading, the bilinguals differ in that they read extensively in English, summarize and make predictions. The monolingual student again excelled in the writing strategy use.

It is interesting that the answers to the questions on translation strategies differed between the two bilinguals. The boy does not translate when he uses any of the four skills while the girl occasionally resorts to translation. The boy also claims to think only in English when using English, while the girl reports reliance on her L1 or L2. In the case of the monolingual girl the answers concerning the role of mental translation are sometimes contradicting.

The bilingual learners also seem to be better communicators since they use more strategies and, in particular, are not reluctant to ask for help or make up words to keep the conversation going. As for vocabulary learning strategies, there is an interesting difference in the type of strategies used. The monolingual girl tends to memorize vocabulary in a more mechanical manner and controls her learning since she keeps a vocabulary book which is regularly checked, while the two bilinguals rely more upon retaining images by creating mental pictures or linking personal experiences to new words.

The next research tool used were numerous English language proficiency tests to check the progress the three students made over the course of three years.

	Bilingual female	Bilingual male	Monolingual female
B2 level	Pass (around 70%)	High pass (around 75%)	Pass (around 70%)
C2 level	Pass (around 70%)	Pass (around 70%)	Low pass (around 60%)

Table 6 Official examination results

All three students reached about the same level of proficiency in English in general and had similar results on particular skills. At both B2 and C2 levels they had the lowest scores on the writing part of the examinations, middle scores on grammar, vocabulary and reading and high scores on speaking. The two bilinguals had significantly better scores on the listening part than the monolingual.

	Bilingual female		Bilingual male		Monolingual female	
	yes	no	yes	no	yes	no
Cognitive strategies						
Reading	13	4	10	7	10	7
Listening	12	4	13	3	6	10

Overall %	64.7	35.3	60.9	39.1	52.3	47.7

Table 7 Task based analysis results

A checklist of strategies (see Table 7) showed that the bilingual girl used 68 (64,7%) out of 115 strategies, the bilingual boy came second with 64 (60,9%) and monolingual girl came last with 55

(52,3%) strategies. The bilinguals exceeded the monolingual particularly in listening strategies, the bilingual boy stood out in speaking strategies and the monolingual girl used most strategies during writing tasks. The bilingual female was the best communicator while both bilinguals used the same number of vocabulary strategies.

Verbal reports that resulted from prompting during task completion and the semi-structured interviews revealed, among others, the following. The bilingual girl reported to be using most strategies from the check lists unconsciously and showed evidence of metalinguistic awareness. When encountering new vocabulary she draws from both L1 Russian and L2 Greek depending on the word closeness to either of the languages. She also guesses from context or analyses word parts to come to understanding. She avoids literal translation as she realizes that it is impossible since, according to her, the syntax of L1, L2 and L3 differ significantly. She reports to be constantly learning from her mistakes but does that in an anxiety-free manner as she is used to encountering unknown vocabulary and expressions in all three languages. She also insists that it is impossible for her to learn grammar or vocabulary by heart. When asked what language is the language of thought she said that she thinks in all three languages depending on the situation and that Russian often helps her with her English and vice versa as they share cognates, but she sometimes finds it confusing and mixes codes, particularly when she lacks the knowledge of Greek vocabulary.

The bilingual boy reported using similar strategies; however, the main difference between the two bilinguals seems to be that the boy claims to think only in the target language when he uses it whether it is Greek, Serbian or English. He finds it difficult to translate in any of these languages and never learns the grammar rules or new vocabulary by heart. He says that he finds it very easy to find patterns in English and that it comes naturally. He makes guesses, tests hypotheses and takes risks in a stress-free way. While in Greece, he thinks in Greek and English and in Serbia in Serbian and English. English seems to pervade as a language from which he constantly draws information.

The monolingual girl reports to be using certain strategies throughout her preparation for the English exams without experimenting with new strategies unless she is instructed by her teacher. She relies heavily on a conscious effort to better herself at English, avoids taking risks and spends a considerable amount of time studying showing awareness of her strong and weak points.

6. Discussion

The bilinguals used more strategies, more frequently: Our SILL findings support the hypothesis that bilinguals use more strategies, more frequently than monolingual learners (Kemp, 2007, Tuncer, 2009). Bilinguals might be more advantageous than monolinguals in the process of language learning having prior language learning experience and being intrinsically motivated. The source of motivation might be previous success at acquiring/learning other languages. In the case of the two bilinguals involved in the specific study, their bilingualism is additive rather than subtractive since the status of their L1 and L2 is not problematic in Greece and their literacy in both Russian and Greek and Greek and Serbian respectively serves as scaffolding when acquiring English with respect to language learning strategies they use.

There was a qualitative difference in strategy use between the bilinguals and the monolingual learner: The bilinguals approach learning both as a system and as a code of communication in ways that indicate creativity, communicative sensitivity and willingness to take risks. The advantage of transferring successful strategy use from previous language learning to the new language learning environment is a major reason for this difference.

The bilinguals tend to transfer more strategies that have to do with implicit rather than explicit language learning since this approach proved to be more efficient when they learned their L2 particularly with respect to vocabulary and grammar. They tend to rely on the typological similarities, such as vocabulary forms between Russian and Serbian and English as there is a lot of borrowing among these languages. Finally, the fact that bilinguals actively use and develop all three languages helps them feel confident and relaxed when encountering language learning difficulties in L3. This characteristic results in differences in the quality of strategy use between the bilinguals and the monolingual learner which concern memory, compensation and affective strategies.

The bilingual female learner used more strategies than the male bilingual: Our findings confirm previous research that gender indeed plays a significant role in strategy use and that females typically report more strategy use than male learners. In our study, the female bilingual learner uses overall more strategies than the male student. Differences were found in memory, cognitive, metacognitive and social strategies but not in affective strategies, which may be contradictory to previous findings (Green & Oxford 1995, Hong-Nam & Leavell 2006). The fact that the monolingual

female exceeds the male bilingual learner in the use of social strategies is also related to the role gender plays, since females are in general more willing to build relationships and use social networks with consistency (Hong-Nam & Leavell, 2006). As for the differences in the use of metacognitive strategies in favor of the monolingual female learner, it confirms findings of previous research that females are more metacognitively aware than males (Green & Oxford 1995, Dreyer & Oxford 1996, Peacock & Ho 2003).

7. Limitations

Ours is a longitudinal case study and as such it has advantages and pitfalls. A case study collects data from a single or several cases and its advantages are rich and deep data coming from multiple sources providing for an intensive study. Its limitations are susceptibility to bias, unsuitability for statistical analysis, etc. Being a longitudinal study it enabled us to track sequential developmental patterns and changes bearing in mind individual differences and acquiring comprehensive data, but it required a long study span, high demand on consistency and lacked statistical significance (Wei & Moyer, eds. 2008).

8. Conclusion-Recommendations

This study provides insights into quantitative and qualitative differences in strategy use by bilingual and monolingual learners when learning a foreign language. We have illustrated that our bilinguals use more strategies, more frequently compared to the monolingual both in relation to strategy groups and skills. Their strategy use shows communicative sensitivity, creativity, willingness to take risks and practice naturalistically. In other words, they seem to have the necessary tools to foster and promote their language learning autonomy beyond the classroom and the teacher's control, which is the main advantage of our bilingual learners over the monolingual one.

More research using a larger sample is required for further investigation of how exactly multilinguals use their strategies. It could be interesting to explore strategy differences in specific types of strategies as well as the clusters and chains of strategies multilinguals use in relation to different skills. Another area worth exploring is the qualitative changes that take place during the development of strategic processing in multilinguals. The final challenge for researchers is to use the knowledge about multilinguals and the strategies they use and integrate it in strategy training programs in order to help monolingual students learn more effectively.

ABSTRACT

This paper discusses the syntax of pronominal clitics in early Cypriot Greek in the light of new evidence from spontaneous speech data, both cross-sectional and longitudinal, as well as experimental data. An elicited production task for 3rd person object clitics was performed by 2-, 3-, and 4-year-olds. The results revealed an interesting discrepancy regarding children's performance in the two critical conditions: enclisis-contexts are adult-like, while in proclisis-contexts children misplace clitics. Our findings are compared with other studies on the acquisition of clitics in Cypriot Greek and we sketch the developmental stages CG-speaking children pass until they reach adult-like clitic placement.

Keywords: Cypriot Greek, Acquisition, Clitics, Syntax

1. Introduction

The syntax of pronominal clitics is one of the most important and well-known differences between Cypriot Greek (henceforth CG) and Standard Modern Greek (henceforth SMG). CG is a Tobler-Mussafia language, in which clitics are banned from clause initial position, with a mixed pattern of clitic placement: clitics either precede or follow the finite verb depending on the syntactic context. On the other hand, SMG is a mainly proclitic language, with clitics immediately preceding the finite verb in all constructions apart from imperatives; in SMG clitics follow the gerund as well. Interestingly, while SMG-speaking children have adult-like clitic production and placement from very early on (Marinis 2000, Stephany 1997), in early CG a non-adult-like pattern of clitic placement has been attested (Petinou & Terzi 2002).

The discussion in this paper revolves around the first language acquisition (henceforth L1A) of clitic constructions in CG. The second section offers a brief overview of the placement restrictions for pronominal clitics in CG in a number of syntactic contexts. The third section presents the research carried out so far on clitic L1 acquisition in CG and points out the main findings as well as the questions that are still open. This leads to a formulation of a number of research questions that need to be answered on the basis of a large database of child data. The fourth section offers a summary of the work carried out on the L1 acquisition of CG clitics by Neokleous and Parodi (Neokleous *to appear*, Neokleous & Parodi *to appear*). The fifth section discusses the phenomenon of clitic misplacement attested at the initial stages of L1A in CG, compares the results obtained from our studies with the outcome of Petinou and Terzi's (2002) study and discusses the stages of language development for young Greek Cypriot children.

¹ This research was conducted within the project "L1 Acquisition of Cypriot Greek Pronominal Clitics" coordinated by Dr. Kleanthes Grohmann (University of Cyprus). This project was funded by Research Promotion Foundation within the program «Young Researchers of Cyprus» (project protocol no. IIENEK/0609/42) of the «Framework Program for Research, Technological Development and Innovation 2009/10» co-funded by the Republic of Cyprus and the European Regional Development Funds.

2. The Syntax of clitics in CG

Cypriot Greek shares with SMG the morphological paradigm of pronominal clitics (table 1). Clitics in both varieties inflect for number, case, person and gender (in 3rd person). The same forms are used in both CG and SMG, with the exception of the feminine plural accusative; in CG only the form *tes* is used, unlike SMG where both *tis* and *tes* are used. In both Greek varieties pronominal clitics, unlike strong pronouns, are morphologically deficient in Cardinaletti & Starke's (1999) sense. They are monosyllabic elements, that cannot be coordinated or stressed and cannot introduce a new referent. Furthermore, they are verb adjacent, with no other element intervening between the clitic and the verbal host.

Number / Case	1 st person	2 nd person	3 rd person		
			Masculine	Feminine	Neuter
Singular					
Genitive	mu	su	tu	tis	tu
Accusative	me	se	to(n)	ti(n)	to
Plural					
Genitive	mas	sas	tus	tus	tus
Accusative	mas	sas	tus	tes	ta

Table 1 The morphological paradigm of Cypriot Greek clitics

Despite the convergence of the two varieties at the morphological level, clitic placement in SMG is very different from clitic placement in CG (Agouraki 2001, Terzi 1999a; 1999b). SMG patterns like Italian and Spanish and exhibits preverbal clitic placement in all syntactic contexts (1, 4-6), except for imperatives (3) and clauses involving gerunds. On the other hand, the main characteristic of CG clitics is that they are banned from clause initial position, like any other clitic language that adheres to the Tobler-Mussafia law. CG clitics never occupy clause initial position, but they either precede or follow the finite verb depending on the syntactic context. While in bare finite clauses CG clitics follow the verb (2), in negatives (5), clauses headed by modal particles (4) or wh-elements (6) the clitic precedes the verb².

- (1) To efera. (SMG)
It-CL bring-1S.+PAST.+PERF
“(I) brought it”
- (2) Efera to. (CG)
Bring-1S.+PAST.+PERF it-CL
“(I) brought it”
- (3) Fer(e) to. (SMG & CG)³
Bring-3S it-CL
- (4) Na to fero. (SMG & CG)
M it-CL bring-1S.+FUT.+PERF
“To bring it”
- (5) (Δ)en to efera. (SMG & CG)
NEG it-CL bring-1S.+PAST.+PERF
“I didn’t bring it”
- (6) Pcos to efere? (SMG & CG)
Who.NOM it-CL bring-3S.+PAST.+PERF
“Who brought it?”

² This is by no means an exhaustive description of enclisis and proclisis contexts in CG. Yet, the focus is on syntactic constructions found in early data. In addition, in these contexts, the choice of one of the two patterns is clear cut, unlike clauses headed by elements realized in the left periphery of the clause, where clitic placement depends on other factors (e.g. Agouraki's (2010) proposal on correlation between enclisis-proclisis alternation and emphasis specification on C).

³ In examples (3-6) SMG and CG pattern alike modulo phonological differences.

If we compare the system of clitic placement in the two varieties with respect to learnability, the SMG pattern constitutes a much more plausible case in relation to the CG pattern. To clarify, young children acquiring SMG need to learn a system that involves pre-verbal clitic placement, with the exception of imperatives and gerunds. The gerundive construction is not frequently used in adult SMG, and it is absent from child speech at the early stages of language acquisition. As for the imperative clause, it constitutes a construction widely used in both child speech and child directed speech. Thus, for SMG-speaking children, the syntax of clitics is acquired once they have established the contrast between imperatives that require post-verbal clitic placement and all other constructions, where clitics immediately precede the finite verb. As expected, and on the basis of acquisition studies in SMG (Marinis 2000, Stephany 1997), clitic placement is adult-like from very early on. However, this is not the case for early CG, since some children exhibit non-adult-like clitic placement at the onset of L1A (Petinou & Terzi 2002, Neokleous *to appear*, Neokleous & Parodi *to appear*). This is not surprising, though, if we take into account the complexity of the system of clitic placement in Cypriot Greek with a number of restrictions imposed on CG clitics. The phenomenon observed at the early stages of L1A in CG is clitic misplacement, which will be discussed in the remainder of this paper on the basis of the results obtained from Petinou & Terzi (2002) study, as well as our studies. The section that discusses our systematic investigation of clitic placement in early CG is preceded by an overview of all the other studies on the L1A of CG clitics so far conducted.

3. L1A of CG Clitics

The first study on the acquisition of clitic constructions in CG was carried out by Petinou and Terzi (2002), who investigated clitic placement on the basis of a corpus of spontaneous speech recordings of five typically developing (henceforth TD) children and five children diagnosed with SLI. Since our paper discusses language development in typically developing populations, we will not discuss the data of the SLI children, but we will rather focus on the performance of children with normal language development. TD children were followed longitudinally within the age range of 32 to 36 months and were recorded three times, with a two-month interval between the recordings. The data analysis Petinou and Terzi conducted involved calculations of the percentages of misplaced clitics in subjunctives and negatives out of the children's overall clitic production in these two construction types. The negative and the subjunctive clause are both proclisis-triggering contexts, thus they require a pre-verbal clitic. Clitic misplacement would involve post-verbal clitic placement. Table 2 summarizes their results and reports the Proportion of Clitic Misplacement (PCM) as well as the MLU (Mean Length of Utterance in words) per child per developmental stage.

Child	32 months		34 months		36 months	
	PCM	MLU	PCM	MLU	PCM	MLU
OX	10% (3/30)	3.0	2% (1/52)	3.6	0% (0/61)	3.3
NA	66% (16/24)	2.8	28% (5/18)	3.1	12% (4/33)	3.3
AM	7% (2/26)	2.8	0% (0/17)	3.2	0% (0/34)	4.0
AI	21% (3/14)	2.4	14% (3/21)	3.0	5% (2/37)	3.4
AX	62% (20/32)	2.9	44%(13/29)	3.1	0% (0/38)	4.0
M	33	2.8	18%	3.2	3%	3.6
SD	28	0.22	16%	0.23	5%	0.36

Table 2 Proportion of misplaced clitics in proclisis contexts (Petinou & Terzi 2002: table 2, pp.13)

The results reported in table 2 reveal the phenomenon of clitic misplacement in proclisis contexts, with the participants exhibiting proportions ranging from 7% to 66% at the first developmental stage at which they were recorded (32 months). In the subsequent two stages (34 and 36 months), the proportions of incorrect clitic placement for all the participants decreases rapidly relative to their performance at the previous stage. By the age of 36 months, three out of five children have reached adult-like clitic placement, with no misplaced clitics, while the other two children exhibit significantly low percentages.

The most important contribution of Petinou and Terzi (2002) was that they were the first to observe and report the phenomenon of clitic misplacement in early CG. Yet, a drawback of their study is the small number of participants. This challenges the generalizability of their results: no safe conclusions can be drawn as to whether all or just a subset of CG-speaking children aged 2;0-3;0 exhibit this non-adult-like pattern for clitic placement. In Petinou and Terzi's (2002) study, the phenomenon is robust only in the speech of two out of five participants. In specific, the percentages of misplaced clitics in the speech of these two children, N.A. and A.X., reach 66% and 62% respectively, while for the other two participants are significantly low, even for the earlier developmental stage reported in the study (for A.M. is calculated at 7% and for O.X. at 10%). For the last child, A.I., the relevant percentage is not high either: it only reaches 21% of his overall clitic production. Thus, the question that remains open is whether all 2- to 3-year old Greek Cypriot children exhibit the phenomenon of clitic misplacement or just a subset of them. And, if the latter is true, the question posed is what is the size of this subset relative to the whole TD population.

Grohmann and colleagues have recently conducted a second study on CG clitics (Grohmann 2011 and Grohmann et al. *to appear*). This study was carried out within COST Action A33, a project aiming to investigate the performance of typically developing children across Europe at the age of 5, with respect to five areas of grammar including clitic production. For the purposes of that project, twenty four typically developing children aged 5 to 6 participated in Grohmann's study (2011) (see table 3), but the test developed within COST project was also administered to a larger group of participants, aged 2- to 7-years (Grohmann et al. *to appear*).

The test developed within COST Action and used by Grohmann and colleagues was a clitics-in-islands test, an elicitation production task for 3rd person singular accusative object clitics within syntactic islands. After the introductory sentence followed by a question, children were confronted with an embedded *because* (*jati*) – clause, which they were prompted to complete; a sample of the experimental material taken from Grohmann (2011) is presented in (7) and the targeted structure is given in parenthesis. All the eight adults that participated in Grohmann's (2011) study as the control group have produced exclusively post-verbal clitics. On the basis of this outcome, Grohmann (2011) and colleagues (Grohmann et al. *to appear*) assumed that the adult-like pattern in this construction type requires post-verbal clitic placement.

- (7) I mama xtenizi ti gorua tfe i korua en omorfi.
 “Mommy is combing the girl and the girl is beautiful”
 Jati i korua en omorfi?
 “Why is the girl beautiful?”
 I korua en omorfi jati i mam:a tis [*htenizi tin-CL*]
 The girl is beautiful because mommy [*combs her*].

We summarize the results for all the children that participated in this study in tables 3 and 4; the former unifies tables 1 and 2 from Grohmann (2011) and the latter is taken from Grohmann et al. (*to appear*).

Age Groups	N	Clitics		Omission	NP	No Answer	Other
3;0-4;0 (N=10)	120	Overall Post-verbal	110 (91.7%) 110 (100%)	2 (1.7%)	3 (2.5%)	0 (0%)	5 (4.2%)
5;0-6;0 (N=24)	288	Overall Post-verbal	276 (95.8%) 139 (50.3%)	2 (0.7%)	2 (0.7%)	1 (0.35%)	7 (2.45%)

Table 3 Results of TD 3- and 4-year-olds for clitics-in-islands test
 (Grohmann 2011: table 1 (pp.193) & 2 (pp.195))

Age Groups	2;0–2;11	3;0–3;11	4;0–4;11	5;0–5;11	6;0–6;11	Control
Overall	98.6%	86.7%	88.5%	94.3%	87.3%	100%
Post-verbal	90.0%	89.0%	88.0%	68.0%	47.0%	100%

Table 4 Clitic production for all age groups for clitics-in-islands test
 (Grohmann et al. *to appear*: table 3)

Based on the results of the studies by Grohmann and colleagues reported in tables 3 and 4, we can argue that CG-speaking children as young as 2 years of age have adult-like clitic production, with percentages ranging between 86.7% and 98.6%. As for clitic placement, no safe conclusions can be drawn on the basis of this study, because, contrary to what is assumed by Grohmann (2011), the construction under investigation, namely *because (jati)* – clauses, may allow for both enclisis and proclisis in CG depending on various factors. For instance, the presence or absence of an overt subject in the embedded clause is an important factor that affects clitic placement. Moreover, an overt subject would yield a different pattern depending on whether it is stressed or not. Notably, Grohmann *et al.* (*to appear*) mention that children got used to the pattern of the test and would produce the *because (jati)*–clause prior the experimenter, yet without clarifying whether the elicited clause in this case would involve an overt subject or not. Grohmann *et al.* (*to appear*) report a mixed pattern of clitic placement not only in 5- and 6-year-olds, but in adult population as well. Therefore, the results of the study in discussion are not indicative for the developmental stages of clitic placement in early CG. They instead reflect sociolinguistic facts, given that one of the available patterns for clitic placement in *because (jati)* – clauses in CG, namely the pre-verbal pattern, resembles the SMG pattern in the corresponding construction. Greek Cypriot children once they attend primary school, where SMG is the means of instruction, show an inclination to the use of the SMG pattern in *because (jati)*–clauses (Grohmann 2011, Grohmann *et al.* *to appear*).

Summarizing the discussion in this section, we point out that the important outcome of the study carried out by Grohmann (2011) and colleagues (Grohmann *et al.* *to appear*) is that CG-speaking children have adult-like clitic production from the onset of L1A. The phenomenon of clitic misplacement observed by Petinou and Terzi (2002) in early CG remains to be further studied on the basis of a larger database and there are a number of research questions that are yet to be answered, such as:

1. Is the phenomenon of clitic misplacement generalizable across participants?
2. Is misplacement attested in proclisis contexts alone or in enclisis contexts as well?
3. At what age do Greek Cypriot children reach adult-like clitic placement?

The research to be described in the following section aims at providing satisfactory answers to the above questions.

4. Method

This section summarizes two studies on the L1 acquisition of CG clitics reported by Neokleous (*to appear*) and Neokleous and Parodi (*to appear*). The aforementioned studies have investigated the acquisition of clitic placement by young Greek Cypriot children, with a monolingual CG-speaking background and no language related or unrelated impairments, nor any behavior problems. In the first part, we discuss a study based on spontaneous speech data, both cross-sectional and longitudinal, reported in Neokleous and Parodi (*to appear*) and in the second part we present the results of an experimental task carried out by Neokleous (*to appear*).

4.1. Spontaneous Data

Our investigation of clitic placement in early CG (Neokleous & Parodi *to appear*)⁴ was based on a corpus comprised of spontaneous speech data from eight monolingual Greek Cypriot children aged 2;3-3;4 while they interacted with the experimenter. We studied clitic constructions triggering the two patterns of clitic placement in CG: structures in which the clitic follows the verb, namely bare finite clauses and imperatives (examples 2-3), and structures in which the clitic precedes the verb, i.e. negatives, wh-questions, clauses headed by modal elements (examples 4-6). Data analysis revealed that all the participants placed clitics post-verbally in enclisis contexts, as in adult language. Yet, in proclisis contexts, a subset of the participants misplaced clitics, namely they placed them post-verbally. The results of data analysis in proclisis contexts are plotted in figure 1. Children's data show a bi-modal distribution: five of them have ceiling percentages of correct and three of them of incorrect clitic placement.

⁴ The data were transcribed following the conventions of the CHAT format (MacWhinney 2010).

Figure 1 Percentages of incorrect clitic placement in proclisis contexts (Spontaneous Data)

Participant S1, one of the children who exhibited ceiling percentages of misplaced clitics, was followed longitudinally from age 2;3 until age 2;10 and was recorded five times. This child was producing exclusively post-verbal clitics for as long as seven months. This result indicates the robustness of the phenomenon observed in early CG.

Taking into account the initial observations from the spontaneous speech study by Neokleous and Parodi, Neokleous (*to appear*) has implemented an experimental task in a larger group of participants to test the generalizability of the results of both Petinou and Terzi (2002) and Neokleous and Parodi (*to appear*) studies.

4.2. Elicited Production

This part is based on Neokleous (*to appear*) and describes the implementation of an experimental investigation of clitic placement in early CG: 50 Greek Cypriot children from three age groups, 2-, 3- and 4-year olds, performed an elicited production task for 3rd person singular object clitics. The task involved twelve pictures from the book “First Hundred Words in English” (edited by Amery & Cartwright 2009) matched with twelve questions. In (8) we offer an example question made by the experimenter and in (9) the expected answer.

- (8) Ti θeli na kami to koritsaki to kaðro?
 What want-3S M do-3S the-ACC girl-ACC the-ACC frame-ACC
 “What does the girl want to do the frame?” [Experimenter]
- (9) Na to kremasi.
 M it-CL hang-3S
 “(She wants) to hang it” [Elicited Clause]

The experiment was designed for the elicitation of pronominal clitics in three construction types: (1) bare finite clauses, (2) negatives and (3) subjunctives. These structures fall within two experimental conditions: the former is an enclisis context (see example 2), while the second and the third are proclisis contexts (see examples 4 - 5). The task aimed to elicit 3rd person singular object clitics; the genitive and the accusative case as well as all the three genders were equally represented in the task. Data analysis took into account only the clauses produced as a response to the corresponding question, i.e. only the subjunctive clauses produced after a question like the one in (8) would count as correct responses.

All the participants produced a good number of clitics in bare finite clauses and in subjunctives, but not in negatives; only 15 out of 50 children produced at least a single negative clause. Thus, negative clauses were disregarded from statistical analysis. The elicited clitic constructions were coded as correct or incorrect; correct clitic placement in subjunctive clauses requires a pre-verbal clitic, while in bare finite clauses a post-verbal clitic. Then, the respective raw numbers and percentages were calculated. Table 2 reports the outcome of data analysis.

Context	Age Group	Placement	
		Correct	Incorrect
FIN	A	47 (100%)	0 (0%)
	B	61 (98%)	1 (2%)
	C	28 (100%)	0 (0%)
SUBJ	A	25 (66%)	13 (34%)
	B	55 (95%)	3 (5%)
	C	27 (100%)	0 (0%)

Table 5 Clitic placement in bare finites and subjunctives.

As we can see from table 5, children from all age groups perform at ceiling regarding clitic placement in bare finites. Yet, in subjunctives, while the participants of the second and the third age group perform adult-like, one third of the children falling within 2;6 and 3;0 years of age produce misplaced clitics. The statistical analysis performed has shown that the difference as for incorrect clitic placement between age groups A and B as well as between age groups A and C reaches statistical significance, with $p < 0.10$ in both comparisons (see Neokleous *to appear* for a detailed description of the statistical analysis conducted).

4.3. Summary

The two studies carried out by Neokleous and Parodi on the L1A of clitic constructions in CG, even though they have implemented different methodologies and have recruited different groups of participants, had the same outcome: they revealed the phenomenon of clitic misplacement attested in the speech of a subset of Greek Cypriot children younger than three years of age.

5. Discussion

The acquisition of CG clitics was systematically investigated in the two aforementioned studies, namely Neokleous (*appear*) and Neokleous and Parodi (*to appear*), and the research questions posed in section 3 can be answered on the basis of the results obtained.

The existence of clitic misplacement in early CG reported by Petinou and Terzi (2002) is verified by our studies as well; the phenomenon is attested in a subset of the participants of both the spontaneous speech study and the experimental investigation. Thus, Petinou and Terzi's outcome is confirmed on the basis of a much larger database of early CG. Moreover, the results from both their and our studies point to the same conclusion as for the generalizability of the phenomenon across participants. Two out of five children in their study and three out of nine children in our spontaneous speech study had high percentages of misplaced clitics. Interestingly, the experimental investigation confirmed that the phenomenon is exhibited by around 30% of Greek Cypriot children whose age falls within 2;6-3;0 years (Neokleous *to appear*). Yet, apart from points of convergence between their study and ours, there are also some points of divergence.

We can, now, proceed to a direct comparison of Petinou and Terzi's study and Neokleous and Parodi's study, given that firstly, the methodology implemented for data collection was the same in both studies (involving samples of spontaneous speech), and secondly, the age range of their (2;8-3;0) and our participants (2;3-3;4) highly overlaps. In figure 2, we plot Petinou and Terzi's results based on table 2 from section 3.

Figure 2 Proportion of misplaced clitics in proclisis contexts
(based on Petinou & Terzi 2002: table 2, pp.13)

A comparison of figure 1 from our study and figure 2 from Petinou and Terzi's (2002) reveals some important differences as for the phenomenon observed, and in specific with regards to: (1) its robustness, and (2) its duration. In relation to the first point, the highest percentage of clitic misplacement reported by Petinou and Terzi is 66% of the overall clitic production, whereas in our study the children who exhibit the phenomenon do so at ceiling percentages. As for the second point, and as shown in figure 2, the three children with high percentages of clitic misplacement at age 2;8 in Petinou and Terzi's (2002) study show a rapid improvement over a period of four months; for instance, A.X. misplaces clitics at 62% at age 2;8, at 44% at age 2;10 and by age 3;0 s/he is adult-like. In contrast, the child we followed longitudinally (Neokleous and Parodi *to appear*) had ceiling percentages of misplaced clitics for as long as seven months.

As for the robustness of the phenomenon, further analysis of a subset of the experimental data reported in Neokleous (*to appear*) confirms Neokleous and Parodi's (*to appear*) outcome: children who misplace clitics do so at ceiling percentages. Moreover, the fact that on the basis of a database including 58 children, we were unable to capture several phases of this transition from the non-adult-like to the adult-like pattern indicates that this transition is quite rapid.

Some concluding remarks on the L1 acquisition of the syntax of CG clitics on the basis of all the aforementioned studies are summarized below:

1. No clitic omission is observed in CG-speaking children after two years of age (Grohmann et al. *to appear*).
2. Clitic placement in enclisis contexts is adult-like from the onset of L1A (Neokleous *to appear*, Neokleous & Parodi *to appear*).
3. Clitic misplacement is attested in proclisis contexts, where children produce post-verbal instead of pre-verbal clitics (Petinou & Terzi 2002, Neokleous *to appear*, Neokleous & Parodi *to appear*).
4. The phenomenon of clitic misplacement is attested in a subset of CG-speaking children representing the 30% of the typically developing population aged 2;6–3;0 (Neokleous *to appear*).
5. Children exhibiting the phenomenon of clitic misplacement do so at ceiling percentages and in all the proclisis-triggering contexts they produce (Neokleous & Parodi *to appear*).
6. All CG-speaking children acquire the syntax of clitics around age 3;0 (Petinou & Terzi 2002, Neokleous *to appear*, Neokleous & Parodi *to appear*).

ABSTRACT

This article investigates which stress pattern emerges as the preferred one in the absence of morphological conditioning in a morphologically-determined system like Greek. More specifically, we explore the stress behavior of a particular category of indeclinable words, namely, acronyms in order to discover whether the antepenultimate default represents the most frequent choice in the speakers' productions. A production experiment revealed that a stress pattern different than the language-specific default emerges in the absence of overt morphological information.

Keywords: acronyms, phonological default, morphologically-determined stress, reading aloud experiment

1. Introduction

Lexical stress systems are referred in the literature as an extreme case of unpredictability in the position of stress. More specifically, in such systems the computation of stress relies heavily on the lexically pre-specified information that morphemes may be endowed with. Naturally, when a string of morphemes is concatenated to form a word, the lexically-assigned stress of a given morpheme may be in conflict with the lexically-encoded stress preferences of other morphemes in a word. The examples in (1) and (2) from Russian and Greek, respectively, are instructive. In (1b), for example, the inflectional ending /-á/ is assumed to be inherently stressed and, as such, it surfaces with primary stress. However, the same ending loses prominence to the inherent stress of the root /bolót-/ in (1d). The same applies to the genitive plural suffix /-ón/ in the Greek examples (2b) and (2d), respectively.

(1) Russian: Inflected neuter nouns in -o (nom.sg), -a (nom.pl)

- | | | | |
|----|---------|------------|----------|
| a. | zérkalo | /zerkal-o/ | 'mirror' |
| b. | zérkalá | /zerkal-á/ | |
| c. | bolóto | /bolót-o/ | 'swamp' |
| d. | bolóta | /bolót-á/ | |

(2) Greek: Inflected feminine nouns in -a (nom.sg), -on (gen.pl)

- | | | | |
|----|----------|-------------|-------|
| a. | thálasa | /thalas-a/ | 'sea' |
| b. | thalasón | /thalas-ón/ | |
| c. | ayeláða | /ayelád-a/ | 'cow' |
| d. | ayeláðon | /ayelád-ón/ | |

Crucially, in the absence of lexically pre-specified stress, a language-specific elsewhere or default stress pattern arises. In our examples, the default is represented by the examples in (1a) and (2a); that

is, it is initial in Russian and antepenultimate in Greek due to a three-syllable restriction that is obligatorily enforced in the language. However, the issue of which stress pattern represents the default is not an easy one to answer. In Russian, for instance, both initial (Halle, 1973, 1997; Kiparsky & Halle, 1977; Melvold, 1990, among others), and post-stem stress (Alderete, 1999, 2001a, 2001b) have both been proposed to represent the default, as shown in (3) and (4), respectively.

- (3) Russian default stress is initial
- | | | | |
|----|-----------|--------------|---------------------|
| a. | gólovy | /golov-y/ | ‘head-nom.pl’ |
| b. | skóvorody | /skovorod-y/ | ‘frying pan-nom.sg’ |
- (4) Russian default stress is post-stem
- | | | | |
|----|----------|------------|---------------|
| a. | gospož-á | /gospož-a/ | ‘lady-nom.sg’ |
| b. | gospož-í | /gospož-i/ | ‘lady-nom.pl’ |

To complicate things more, a series of nonce-probe experiments on Russian (Nikolaeva, 1971; Crosswhite, Alderete, Beasley, & Markman, 2003) revealed that the speakers’ productions favored stem-final stress. These results are complemented by the findings of recent (experimental) studies (Andreev, 2004; Fainleib, 2008; Lavitskaya & Kabak, 2011a, 2011b) which appoint stem-final stress as the default in consonant-ending words and penultimate stress as the default in vowel-ending words in Russian.

Similarly in Greek, most analyses appoint antepenultimate stress as the phonological default (Malikouti-Drachman & Drachman, 1989; Ralli & Touratzidis, 1992; Revithiadou, 1999, 2007; Apoussidou, 2003; Burzio & Tantalou, 2006) whereas experimental studies that include reading tasks of pseudowords revealed that speakers show a strong preference for penultimate stress (Protopapas, Gerakaki, & Alexandri, 2006). As evident from the above discussion, it is far from clear which stress pattern represents the default.

In order to shed light on this issue, we examine how stress in a morphology-dependent system like Greek is shaped when: (a) morphology is inert, that is, when elements that normally interfere through their underlying stress in accentuation, such as inflectional suffixes, are not available to the speaker, and (b) the stem lacks inherent accentual properties. For this purpose, we designed and conducted a production experiment using infrequent/unfamiliar acronymic constructions as stimuli. Acronyms constitute an ideal case study because they lack fixed stress and, more importantly, they come in specific word sizes and syllable shapes, which allows us to exercise better control of the factors that may influence stress assignment.

The remainder of this paper presents a detailed account of a production experiment and its results, and provides a valuable insight in the nature of ‘default’ in morphology-dependent stress systems like Greek.

2. Acronyms

Acronymic constructions are very productive and common in everyday use. Unlike the vast majority of the Greek vocabulary, they are inflectionless and are deprived of pre-assigned stress.¹ The latter characteristic distinguishes them from place names, loanwords and brand names (e.g., Monacó, Sóftware, Lacóste, etc.) which are usually endowed with an inherent accentual property.

According to Anastassiadis-Symeonidis (1986) acronymic constructions in Greek, together with various types of initialisms (e.g., M.M.E. [mí mí épsilon] /mésa mazikís enimérosis/ ‘Mass Media’, Φ.Π.Α. [fí pí á] /fóros prostiθέmenis aksías/ ‘Value Added Tax’) are instances of word creation (Booij, 2005). Acronyms are formed by extracting a portion from the beginning of words that belong to the same nominal phrase and by linearly arranging them into a template-shaped construction (Vazou, 2004; Vazou & Xydopoulos, 2007; Nikolou, 2010). More specifically, they can be formed: (a) by copying the initial segment of the constituent words (5a), (b) by copying parts of the initial syllables that are the size of a close or an open syllable (5b), and (c) by both the above ways (5c):

- (5) a. [ika] /ðírima Kinonikón Asfalíseon/ ‘Social Security Organization’

¹ Only highly frequent ones, which are felt as common words, e.g., A.E.K. [áek] ‘Athletic Union of Constantinople’, E.A.TA. [eltá] ‘Hellenic Post’, etc. have fixed stress.

- b. [ðipeθe] /DImotikó PERiferiakó ΘEatro/ ‘Municipal Regional Theater’
 c. [eiðap] /Etería IDrefsis Apoxétefsis Protévusas/ ‘Athens Water Supply and Sewerage Company’

Sizewise, Greek acronyms are mostly monosyllabic and disyllabic. Three- and four-syllable long acronyms are less frequent or rare. Table 1 presents a list of the attested and unattested acronymic templates in Greek. Interestingly, trisyllabic and quandrisyllabic acronyms with a closed syllable in a non-final position are practically unattested.

	attested acronymic templates	unattested /rare acronymic templates
2σ	CV.CV CVC.CV CV.CVC CVC.CVC	—
3σ	CV.CV.CV CV.CV.CVC	CV.CVC.CV CV.CVC.CVC CVC.CV.CVC CVC.CV.CV (rare)
4σ	—	CV.CV.CV.CV (rare) all others

Table 1 Shapes and sizes of attested and unattested acronyms

3. Reading aloud experiment

The purpose of this experiment was to investigate the stress patterns that arise in both vowel- and consonant-ending acronyms and to unveil the factors that determine stress. For this reason, we designed and conducted a reading aloud experiment. In this section, we present the main methodological tools and we report on the main results of our experimental task.

3.1 Methodology

3.1.1 Participants

Twenty-one Greek students of the Aristotle University of Thessaloniki (19 females and 2 males; mean age: 18.1 years, age range: 18-19 years old) participated in the experiment. All of them were native speakers of Greek and naive as to the purpose and scope of this research. Students were awarded a 0.5 grade for their participation in the experiment.

3.1.2 Materials

The experimental stimuli consisted of 140 sentences of a simple SVO order. There was a gap in the subject position which had to be filled with a non-frequent acronym (e.g. T.E.A.Δ.Y. [teaði] ‘Insurance Aid Fund of Public Servants’) or a pseudoword. The relevant item was provided next to the gap. There were 60 gaps for non-frequent acronyms and 80 gaps for pseudowords/fillers. The factors our items were controlled for were: (a) the type of final segment (consonant vs. vowel), (b) the size of the word (two- vs. three-syllable words), (c) the effect of syllable type, i.e. close vs. open penultimate syllable.

Given that there are six attested types of acronyms in Greek (depending on size and syllable structure, see Table 1), we used 10 items for each template and hence 60 experimental stimuli in total. There were 40 gaps for disyllabic acronyms and 20 gaps for trisyllabic ones. These data were

interspersed with fillers/pseudowords, constructed from the most productive morphological classes.² More specifically, we constructed 10 items for each class, hence 40 disyllabic and 40 trisyllabic pseudowords were employed for the experiment. We collected 2940 items in total, which were codified by the experimenters according to speaker, type of word (acronym or filler), word size and stress pattern. A sample of the experimental material is provided in Appendix A. A complete list of all the acronyms used in the experiment is given in Appendix B.

3.1.3 Procedure

The experiment took place in a quiet room, where the participants were individually tested by the first author. The participants were asked to read out 140 sentences containing an acronym or a pseudoword (filler) presented as a power point presentation on a laptop screen. Each slide contained five SVO sentences with a gap in the subject position. The acronym or filler was given next to the gap in capital letters, which required no diacritic for stress, and in a simplified orthography. The speaker was free to choose the gender for each word s/he filled in the gap with. The participants' responses were recorded with the help of a Marantz PMD661 digital recorder and a Sennheiser E-901 microphone. There was no time limitation in the completion of the task although most participants completed the experiment within 30 minutes.

3.2 Results

The experimental procedure yielded 960 data points (60 acronyms x 21 participants). Table 2 demonstrates the overall stress pattern attested in the data assembled.

Stress pattern	Percentages	Raw numbers
U	72.06%	908
PU	27.14%	342
APU	0.80%	10
Sum	100%	1260

Table 2 Overall stress pattern of acronyms

As shown in Table 2, stress on the ultimate syllable (U) is strongly preferred compared to stress on the penultimate syllable (PU). Strikingly, APU stress, that is, the phonological default by all analyses of Greek stress, is highly under-represented in the speakers' productions. In what follows, we delve more thoroughly into the factors that affect the position of stress in the acronym constructions under examination. More specifically, we focus on the type of the final segment, the role the size of the acronym and the type of its final syllable have on stress.

3.2.1 Type of final segment and size of acronym

The multiple regression analyses revealed that the final segment affected stress. Therefore, we examine separately the stress patterns of acronyms ending in consonants from those ending in vowels. Within each category, we also address the impact of word-size. We begin by focusing on acronyms ending in consonants (Figure 1). Our speakers show a strong preference for stem-final stress ($\chi^2_{(2)}=957.800$, $p=.000$) regardless of the number of syllables since the percentage of U stress is significantly high in both disyllabic ($\chi^2_{(1)}=268.800$, $p=.000$) and trisyllabic acronyms ($\chi^2_{(2)}=346.200$, $p=.000$).

² Fillers/pseudowords were constructed on the basis of real words by changing: (a) the initial vowel of the stem and (b) the initial and final consonants of the stem, while respecting the syllabic structure and the phonotactic restrictions of the language.

Figure 1 Stress results in C-final acronyms

The situation is dramatically different in V-ending acronyms, as shown in Figure 2:

Figure 2 Stress results in V-final acronyms

The difference among the stress responses is statistically significant ($\chi^2_{(2)}=296.067$, $p=.000$), which is due to the few APU responses. However, the preference for U over PU stress was found to not be significant ($p>.1$). Interestingly, speakers are split between PU and U stress when confronted with disyllabic acronyms ($\chi^2_{(1)}=.086$, $p=.770$). Three-syllable long acronymic constructions, on the other hand, show a robust preference for U stress (U vs. PU: $\chi^2_{(1)}=12.376$, $p=.000$; U vs. APU: $\chi^2_{(1)}=103.910$, $p=.000$), which suggests that, if the final syllable is open, the number of syllables seems to affect the position of stress.

3.2.2 Syllable type of PU

Our experiment was also designed to check whether the closed- or openedness of the PU has an effect on the position of stress. Figures 3 and 4 illustrate the impact of the PU syllabic structure on the stress patterns in consonant- and vowel-ending acronyms, respectively.

Figure 3 Stress in 2σ C-final acronyms depending on the syllable type of the PU

Figure 4 Stress in 2σ V-final acronyms depending on the syllable type of the PU

As shown in the above figures, a closed PU attracts stress more than an open one. However, the closedness of the PU was found to not have a statistically significant impact on C-final acronyms ($p > .1$). However, it had a marginally significant effect on stress in V-final acronyms ($\chi^2_{(1)} = 3.439$, $p = .064$, $\eta^2 = .090$, Cramer's $V = .090$, Contingency Coefficient = .090). We infer from these results that in C-final acronyms a final closed syllable attracts stress more than a PU one regardless of whether the latter is open ($\chi^2 = 150.876$, $p = .000$) or closed ($\chi^2 = 118.876$, $p = .000$).

4. Discussion and concluding remarks

The results of the production experiment show a marked preference for U or stem-final stress in C-final acronyms and a curious vacillation between PU and U stress in V-ending acronyms. The latter category presents us with the most intriguing stress patterns because the position of stress seems to hinge on the overall size of the acronym, a finding that future analyses of Greek stress ought to take into consideration. In general, the outcome of the statistical analyses suggests that the type of final segment and the syllabic composition of the acronym are controlling factors for the position of stress; final closed syllables attract stress more than open ones. Furthermore, a closed penultimate is more likely to attract stress than an open one.

Importantly, the elsewhere pattern, that is, APU stress, which takes charge of accentuation when morphemes lack lexical stress, is virtually absent in our data. This result clearly shows that, in the absence of morphological conditioning, default stress subsides to the dictates of the inherent stress-encoding mechanism which promotes instead PU and U stress. In other words, the speakers of a

morphology-determined stress system like Greek, who have tacit knowledge of the abstract representation of stress in their Mental Lexicon, feel more comfortable applying the lexical stress-encoding mechanism when confronted with new or unknown words than the predictable APU default.

PRAGMATEMES (ΠΡΑΓΜΑΤΗΜΑΤΑ): THEORY AND THEIR “PREMIÈRE” IN GREEK

Lena Papadopoulou

Democritus University of Thrace, Greece

papadopoulou.lena@gmail.com

ABSTRACT

The purpose of this paper is three-fold. First, it aims to present the theoretical framework of pragmatemes. Second, the lexicographical treatment of pragmatemes is described step by step, from the formation of the macrostructure to the compilation of the microstructure. Third, applications of the PragmaDiG (Dictionary of Greek Pragmatemes) to Greek language learning by English and Spanish speakers as well as to the human and machine translation of pragmatemes of the language pairs Greek-English and Greek-Spanish are presented.

Keywords: phrasemes, pragmatemes, lexicography, language learning, machine translation

1. Introduction

Everyone knows how to thank someone for a favor, a gift, felicitations or how to greet someone they meet; many people can do that in various languages, as well. However, when the communicative situations are demanding and require the production of more precise utterances this is not the case. Non native speakers, alike native speakers in many cases, have a certain difficulty in the selection of the appropriate expression that suits each specific situation best, as, for example, what to say at a funeral (i.e. *My condolences*), how to start a formal letter (i.e. *Dear Mr./Mrs*), what to say when we first meet a person (i.e. *Nice to meet you*), etc. All these ready-made greetings and warnings, standard phrases used in letters, conversational formulas, small texts on official signs, etc. are semantically and formally fully compositional and are called pragmatemes according to Mel'čuk (1998).

The term *pragmateme* is the central notion of this paper. My work is based, on the one hand, on the Mel'čuk's pragmateme theory (1998, (to appear) which makes part of the Meaning⇌Text Theory (Mel'čuk, Clas, & Polguere, 1995) and, on the other hand, on Blanco's lexicographic model for pragmatemes (to appear) (2010). The outline of the specific theoretical framework is followed by the detailed description of the compilation of the Greek Pragmatemes Dictionary (PragmaDiG). Finally, two major applications of PragmaDiG - the learning of Greek by Greek native speakers, English and Spanish speakers as well as the machine and human translation for Greek-English and Greek-Spanish pairs- will be discussed.

2. Theoretical framework

The subject-matter of my study lends itself well to a focus on phraseology around which pragmatemes are clustered. A broad definition of phraseology is 'the linguistic discipline that analyses phraseological, i.e. pre-established, constructions' (Langlotz, 2006, p. 7). Phraseological structures are reported in the specialized literature on phraseology under various denominations, such as *phraseological units* (Chernuisheva, 1964; (Gläser, 1988)), *set combinations* (Zgusta, 1971), *phrasemes* or *set phrases* (Mel'čuk, 1988) and *word combinations* (Cowie, 1988; Howarth, 1966), as Cowie quotes (1998). However, I will adopt the term *phraseme* proposed by Mel'čuk (1998) and used by Blanco (to appear), as their work on pragmatemes is the frame within which my study was undertaken.

Before proceeding further with pragmatemes definition, it is considered important to clarify what we mean when we refer to phrasemes. The most useful way to understand phrasemes is to compare them to free phrases. The comparison is carried out using the concept of linguistic sign introduced by

Saussure and Mel’čuk (1998). However, the notions will only be referred to as a general outline. On the one hand, Saussure states that a linguistic sign X is the combination of a signified “ X ” and a signifier $/X/$, which can be represented as $X = \langle \text{“}X\text{”}; /X/ \rangle$. On the other hand, Mel’čuk adds to the saussurian model the syntactic combinatory Σx of the linguistic sign with other signs, so as mel’čukian sign can be presented by the equation $X = \langle \text{“}X\text{”}; /X/; \Sigma x \rangle$. However, in order to seize how Mel’čuk perceives the linguistic sign and, therefore, the phrasemes typology, it is important to crystallize some preliminary notions of the Meaning \Leftrightarrow Text Theory through the description of an utterance production (Mel’čuk, 1998). An utterance production can be summarized by the following scheme:

Image 1 Utterance production scheme (Cowie, 1998: 25)

The above scheme assumes three representations of the utterance (Mel’čuk, 1998):

- (i) the conceptual representation (RConcept) which consists of the mental reflection of the reality as it is perceived by the speaker as to the situation that (s)he wants to verbalize,
- (ii) the semantic representation (RSem) that the speaker constructs based on the Concepts-Meaning Model (CMM) of his/her language **I** associating elements and configurations of the conceptual representation with those of the corresponding semantic representation and, finally,
- (iii) the phonetic representation (RPhon) that the speaker constructs based on the Meaning-Text Model (MTM) of his/her language **I**, associating elements and configurations of the RSem with all the linguistic elements that compose the corresponding utterance.

The difference between a free phrase and a phraseme is elucidated according to the above scheme. A free phrase $A \oplus B$ of a language **I** is represented as follows:

$$A \langle \text{“}A\text{”}; /A/ \rangle \oplus B \langle \text{“}B\text{”}; /B/ \rangle = A \oplus B \langle \text{“}A \oplus B\text{”}; /A \oplus B/ \rangle$$

The main characteristic of an utterance **AB** which is a free phrase is its freedom which refers to:

- (i) the unrestricted selection:
The meanings and the lexical units of the utterance are arbitrarily selected according to the lexicon rules of the **I**.
- (ii) the regular combination according the grammar rules of the **I**:
The components of the utterance **AB** are combined according to the general grammar rules of the **I**.

An utterance **AB** is not free when the construction of its signifier and signified presents either restrictions at the lexical level or irregularities at the combination of its components. For example, the utterance [apayorevete to kapnisma] *Απαγορεύεται το κάπνισμα* (EN: *No smoking*, SP: *Prohibido fumar*) that frequently is found in signs in public places is a phraseme that presents a restriction at the lexical level; we cannot use for the above mentioned situation another quasi-equivalents of this phraseme, as i.e. [min kapnizete] *μην καπνίζετε* ‘No smoke’ [apayorevete to tsiyaro] *απαγορεύεται το τσιγάρο* ‘Cigarette is forbidden’, although it is allowed by the general rules of the Greek language.

Once the difference between a free phrase and a non free phrase has been clarified and the term phraseme has been selected, the typology of phrasemes that is here utilized will be defined, given that each typology implies not only terminological differences but a different internal categorization as well. For instance, Cowie (1998) recognizes a common primary division of phrasemes:

- (i) *sentence like or pragmatic units* that function pragmatically
- (ii) *word like or semantic units* that function syntactically

This division corresponds to the categorization of *phraseological units* to *propositions* and *nominations* by Gläser (1988), *word combinations* to *functional expressions* and *composites* by Cowie (1988), *phrasemes* to *pragmatic phrasemes* or *pragmatemes* and *semantic phrasemes* by Mel'čuk (1988) and *word combinations* to *functional expressions* and *composite units* by Howarth (1966).

This paper focuses on the double mel'čukian division of phrasemes to *pragmatemes* and *semantic phrasemes*. On the one hand, we refer to a pragmateme when for a given RConcept there is only one signified "X"="A ⊕ B" which is constructed restrictedly and it is articulated only with the given signifier /A ⊕ B/. However, there are cases when the "A ⊕ B" can be replaced by a quasi-synonymous expression.

On the other hand, a semantic phraseme is constructed unrestrictedly and regularly. In other words, for a given RConcept we can select a signified "A ⊕ B" according to the general rules of the language I whose signifier /X/ is constructed restrictedly. For example, if we have the signified "X" = "A ⊕ B" its signifier is /X/≠/A ⊕ B/. The semantic phrasemes according to the correspondence signified-signified are triple divided in:

- (1) idioms or full phrasemes (<"C"; /A ⊕ B/)
- (2) collocations or semi-phrasemes ("A ⊕ C"; /A ⊕ B/)
- (3) quasi-idioms or quasi-phrasemes (<"A ⊕ B ⊕ C"; /A ⊕ B/)

3. Pragmatemes

A definition of pragmatemes is that a phraseme AB (AB) is called a pragmatic phraseme or a pragmateme, if it is restricted to its signified and its signifier by the extralinguistic situation SIT in which AB is used, that is, by pragmatic factors (Mel'čuk, 1998).

In this definition the communicative situation SIT is emphasized, which brings us to the conceptual representation (RConcept) of the Meaning ⇔ Text Theory. The SIT is the key point for the distinction between the pragmatemes and the semantic phrasemes. By SIT we refer to the extralinguistic situation in which speakers find themselves and about which they want to express something. The RConcept gathers all the information that speakers have at their disposal of the given SIT which helps them to verbalize all that they want to say in view of the given SIT. Namely, the SIT affects the respective RConcept and therefore the rest of the representations of an utterance. In the production of an utterance the RSem follows the RConcept. The transition from the RConcept to the RSem is the point where an utterance is phraseologized by pragmatic factors. It is the point where the SIT_{AB} obliges the RConcept to use a particular signified "AB". The utterance in its last representation, in the RPhon, is also bound by the SIT_{AB} which demands a particular signifier /AB/. In other words, the SIT_{AB} determines the signified "AB" and the signifier /AB/ of the pragmateme AB, ignoring the alternative options that the rules of a language I allow.

The great majority of pragmatemes occur in greetings, conversational formulas and signs (Mel'čuk, en prensa). In the following examples (1-5) representative pragmatemes are presented in italics with their respective communicative situation annotated in brackets and in Arial:

- (1) [prohibitory sign in public places]
GR: *Απαγορεύεται το κάπνισμα*
EN: *No smoking*
ES: *Prohibido fumar*
- (2) [answer to an introduction]
GR: *Χάρηκα για τη γνωριμία!*
EN: *Nice to meet you!*
ES: *¡Mucho gusto!*
- (3) [closing a formal letter]
GR: *Με εκτίμηση*
{Name}
EN: *Yours faithfully*
{Name}
ES: *Atentamente*
{Name}
- (4) [take leave of someone]

- GR: *Αντίο!*
 EN: *Goodbye!*
 ES: *¡Adiós!*
- (5) [on a food packaging]
 GR: *Ανάλωση κατά προτίμηση πριν από {DATE}*
 EN: *Best before {Date}*
 ES: *Fecha de consumo preferente: {Date}*

A main characteristic of pragmatemes is that in many cases they present multimodality (Blanco, to appear). There are pragmatemes, especially those that appear on official signs, that can be accompanied or totally replaced by an icon, as, i.e., the pragmateme *Απαγορεύεται το κάπνισμα* (EN: *No smoking*, SP: *Prohibido fumar*) (example 1) can get the following forms (Image 2 and 3):

Image 2 Multimodal pragmateme

Image 3 Pragmateme replaced by an icon

It is beyond any doubt to mention that by the term pragmateme apart from the compositional pragmatic phrasemes there are also non compositional pragmatic phrasemes whose structure presents not only restriction in their signified but in their signifier as well (Blanco, 2010):

- (6) [to a pregnant woman]
 EL: *Καλή λευτεριά!*
 EN: lit. *Good freedom!*
 SP: lit. *¡Buena liberación!*

In addition, under the term pragmateme the pragmatic lexemes are classified, as well. The only difference between pragmatic phrasemes and pragmatic lexemes is that the latter consists of only one lexical unit, as those that we can see in the following example:

- (7) [on a sign of a real estate]
 EL: *Ενοικιάζεται*
 EN: *For rent*
 SP: *Se alquila*

4. Lexicographical treatment of pragmatemes

A lexicographical treatment of pragmatemes should start from the fact that pragmatemes are not lexical units -although they are linguistic signs disposed of a signified, signified and syntactic combinatory- because they present an internal argumental structure (Blanco, 2010). Thus, pragmatemes cannot constitute entries in a dictionary of lexical units but entries of an inventory of textual units (Blanco, 2001).

Fertile ground for the lexicographical formalization of pragmatemes should be the explicative and combinative type dictionaries (Blanco, 2010), such of French (Mel'čuk & al., 1984, 1988, 1992, 1999) in which pragmatemes should appear like subentries in the principal macrostructure, such as the non standard lexical functions. Such integration of pragmatemes in a dictionary of lexical entries is realized through the lexical anchor, which is a lexical unit that characterizes the SIT that binds the pragmateme and with which the subentry of the pragmateme is associated, as Blanco cites (to appear). For example, the lexical anchor of the pragmateme (example 5) *Best before {Date}* should be FOOD or PACKAGING.

Although we do not have at our disposal of an explicative and combinative dictionary of Greek, the lexicographic treatment of Greek pragmatemes became realizable through the lexicographical model for pragmatemes proposed by Blanco in his work entitled “Microstructure Évolutive pour un Dictionnaire de Pragmatemes” (to appear), the structure of which is presented below.

4.1 Macrostructure

The macrostructure of the dictionary of Greek pragmatemes (henceforth PragmaDiG) consists of pragmatic lexemes and pragmatic phrasemes. Main source of the pragmatemes has been constituted the previous lexicographical work on Greek pragmatemes (Papadopoulou, 2010)

Given that this work is not exhaustive in compiling all the pragmatemes of Greek language -since it would be impossible- the work was limited to the compilation of pragmatemes that are associated with a certain number of predefined communicative situations, as we can see in the examples 9 and 10. In this way, the systematic formalization of pragmatemes has been ensured. An inverse procedure, defining first the pragmateme and then associating it with its SIT (example 8), would cause formalization and dispersion problems in the description of the SITs, which are the key point of pragmatemes.

- (8) *Χρόνια πολλά!*
 EN: lit. *many years*
 SP: lit. *muchos años*
 [congratulate someone on his birthday]
 [congratulate someone on his saint's day]
 [greeting someone during the Christmas period]

- (9) [congratulate someone on his birthday]
 EL: *Χρόνια πολλά!, Πολύχρονος, Να τα εκατοστήσεις, Να τα χιλιάσεις!*
 EN: *Happy Birthday!*
 SP: *¡Cumpleaños feliz!*

- (10) [congratulate someone on his saint's day]
 EL: *Χρόνια πολλά!, Να χαίρεσαι τη γιορτή σου!*
 EN: *Happy Saint's Day!*
 SP: *¡Felicidades por tu santo!*

4.2 Microstructure

The microstructure of PragmaDiG is articulated in nine main fields which intend to describe each pragmateme in an exhaustive way. The compilation of the microstructure has followed precisely the lexicographical model for pragmatemes by Blanco (2010, to appear) and it is represented by the following fields:

- (i) <MORPHOSYNTAX>
- (ii) <LEXICAL ANCHOR>
- (iii) <SITUATION>
- (iv) <SPEECH ACT>
- (v) <LEXICAL FUNCTION>
- (vi) <PARADIGM>
- (vii) <SYNONYMY> and <ANTONYMY>

- (viii) <DIASYSTEMATICS>
- (ix) <TRANSLATION EQUIVALENCE>

4.2.1 <MORPHOSYNTAX>

In the first field of the microstructure of PragmaDiG the lemma is described morphosyntactically. The description is carried out by means of the six deep-syntactic parts of speech (Mel’čuk, 2006) that are assigned to each component of the pragmateme:

- (i) Nominal
- (ii) Verbal
- (iii) Adjectival
- (iv) Prepositional
- (v) Adverbial
- (vi) Clausal

In the following examples (11 and 12) the morphosyntactic structure of the pragmateme *Λειτουργούμε με συνεχές ωράριο* and *Ναι!* is presented:

- (11) [on a store sign]
EL: *Λειτουργούμε με συνεχές ωράριο*
<V PREP ADJ N>
EN: Open All Day Long
SP: Abierto todo el día
- (12) [in a phone answer]
EL: *Ναι!*
<CLAUSE>
EN: *Hello!*
SP: *¡Dígame!*

4.2.2 <LEXICAL ANCHOR>

The lexical anchor provides semantic information of the pragmateme. By the lexical anchor we mean the lexical unit that phraseologically binds a pragmateme (example 13). It is worth mentioning that a pragmateme can have more than one lexical anchors and that the lexical anchor does not necessarily appear in the pragmateme but it forms part of its semantics. In the following example it is shown how the lexical unit of ΤΣΙΓΑΡΟ binds a series of pragmatemes:

- (13) EL: ΤΣΙΓΑΡΟ
Απαγορεύεται το κάπνισμα
Χώρος καπνιστών
Ευχαριστούμε που δεν καπνίζετε
EN: SMOKING
No smoking
Smoking area
Thank you for not smoking
SP: *Prohibido fumar*
Area de fumadores
Gracias por no fumar

4.2.3 <SITUATION>

The communicative situation SIT provides information about the conceptual structure of the pragmateme. Especially, it thoroughly indicates all the necessary information about the use of pragmateme, such as temporal and spatial coordinates.

For example, if we consider the following pragmatemes, we can observe how a temporal coordinate can differentiate the use of each pragmatic phraseme:

- (14) [greet someone in the morning]
EL: *Καλημέρα!*
EN: *Good morning!*
SP: *¡Buenos días!*
- (15) [greet someone in the afternoon]
EL: *Καλησπέρα!*
EN: *Good evening!*
SP: *¡Buenas tardes!*
- (16) [greet someone on Monday]
EL: *Καλή βδομάδα!*
EN: lit. *Good week!*
SP: lit. *¡Buena semana!*
- (17) [greet someone on the first day of the month]
EL: *Καλό μήνα!*
EN: lit. *Good month!*
SP: lit. *¡Buen mes!*

4.2.4 <SPEECH ACT>

In the fourth field, the speech act that each pragmateme performs is indicated. By the annotation of the speech act we obtain the pure characterization of the lemma, as the speech act is the central predicate of the pragmateme. Representative examples of the speech act annotation follow:

- (18) to prohibit
EL: *Απαγορεύεται το παρκάρισμα*
EN: *No parking*
SP: *Prohibido aparcar*
- (19) to inform
EL: *Κλειστό*
EN: *Closed*
SP: *Cerrado*
- (20) to warn
EL: *Προσοχή ναρκοπέδιο*
EN: *Danger minefield*
SP: *Aviso campo de minas*

4.2.5 <LEXICAL FUNCTION>

The annotation of the lexical functions is considered to be a major determinant of information for the description of pragmatemes. By means of lexical functions **f** we can preview the concurrence of the components of the pragmateme and elucidate the syntactic-semantic role that the **f** represents contingent on the word **W0** with which is associated (Mel'čuk & Zolkovsky, 1988). It is worth mentioning that the lexical functions present a great variety, as, apart from the simple lexical functions, non standard lexical functions were used as well, allowing a more detailed description.

In the following examples we can observe the values that the lexical functions can provide to the pragmateme *Τα συλλυπητήρια μου* 'My condolences':

- (21) EL *Τα συλλυπητήρια μου*
Ver(συλλυπητήρια) = ειλικρινή
MagnVer(συλλυπητήρια) = βαθύτατα
EN: *My condolences*
MagnVer(condolences) = deepest
Ver(condolences) = sincere
SP: *Mis condolencias*

MagnVer(condolencias) = profundas
Ver(condolencias) = sentidas

4.2.6 <PARADIGM>

The paradigm of a pragmateme refers to all the possible forms that the lemma comprises. In the following example we can see how a series of variants are enclosed within a phraseme:

- (22) EL: Υποχρεωτικά φοράτε ΣΥΓΚΕΚΡΙΜΕΝΟ ΕΞΟΠΛΙΣΜΟ
Υποχρεωτικά φοράτε κράνος
Υποχρεωτικά φοράτε γυαλιά προστασίας
Υποχρεωτικά φοράτε ωτοασπίδες
EN: CERTAIN EQUIPMENT required
Hard hats required
Safety glasses required
Ear protection required
SP: CIERTO EQUIPO requerido
Sbrero de seguridad REQUERIDO
gafas de seguridad REQUERIDAS
protección de los oídos REQUERIDA

Although the annotation of the paradigm is of great importance, as it supports the systematic formalization of the variants, it requires a complex procedure, as the relations *in absentia* of the components of a pragmateme are indicated.

4.2.7 <SYNONYMY> and <ANTONYMY>

In this field, the semantic relations of synonymy and antonymy among the pragmatemes are presented. It is worth mentioning, especially for the synonymy, that the synonyms are simply listed and their semantic differentiation is clarified by the means of their diasystematics. It is also worth mentioning that the synonymy and the antonymy of pragmatemes that belong to different semiotic systems have been also taken into consideration.

- (23) EL: Επιτρέπεται το κάπνισμα
Χώρος καπνιστών
Απαγορεύεται το κάπνισμα
EN: Smoking is permitted
Designated smoking area
No smoking
SP: Permitido fumar
Area de fumadores
Prohibido fumar

4.2.8 <DIASYSTEMATICS>

The assignation of diasystemic marks to the pragmatemes provides precision to the conditions of their use. The annotation of the diasystemic followed the eleven-fold categorization proposed by Hausmann (1989), as Blanco cites (2001): (i) diachronic, (ii) diatopic, (iii) diaintegrative, (iv) diastratic, (v) diaconnotative, (vi) diatechnical, (vii) diafrequential, (viii) dianormative, (ix) diamediatric, (x) diaphasic and (xi) diatextual.. The diasystematic marks, in the most of the cases, play a key role in clarifying the synonymy between synonym pragmatemes.

Representative examples are given above, where the diametric (example 24, 25 and 26) is marked by the oral, the diastatic (example 25) is marked by Italicism and the diachronic (example 26) is marked by archaic:

- (24) Vulgar, oral
EL: *Γεια χαραντάν!*
EN: *Hey!*
SP: *¡Buenas!*
- (25) Oral, italicism,
EL: *Τσάο!*
EN: *Chao!*
SP: *¡Chao!*
- (26) Oral, archaic
EL: *Εις υγείαν!*
EN: *Wassail!*
SP: *¡Que sea por muchos años!*

4.2.9 <TRANSLATION EQUIVALENCE>

The last field of the microstructure is dedicated to the translation equivalence of Greek pragmatemes to English and Spanish. Before proceeding to the description of the elaboration of this field, we have to bear in mind that pragmatemes are not lexical units and thereupon they require a particular lexicographic treatment, which is based mainly on pragmatic criteria.

The translation equivalence assignment follows the lexicographical model of *Monolingual Coordinated Dictionaries* by Blanco (2001), according to which the equivalence is provided linearly taking into account the information provided in the microstructure and especially the communicative situation. The emphasis on the SIT is justified by the fact that the communicative situation encompasses the cultural aspects, whose consideration was pointed out by Teliya, Bragina, Oparina and Sandomirs (1998), who characterize phrasemes as cultural language, and Sapir (1964) and Worf (1956), who quote that each language conceptualize the reality on a cultural base, among others.

The cultural aspect that the pragmatemes enclose has haunted us during the elaboration of the translation equivalents which are classified in three major categories (Kromann, Riiber, & Rosbach, 1991):

- (i) full equivalents
- (ii) partial equivalents
- (iii) zero equivalents.

The first type of equivalence is quite rare. In the examples 27 and 28 we can see full equivalents among the three languages. However, in the example 28 it can be observed that in the English and in the Spanish equivalents a religious connotation is marked, contrary to the Greek language where this dialog is considered common during the period of Easter.

- (27) EL: *Καλό ταξίδι!*
EN: *Have a nice trip!*
SP: *¡Buen viaje!*
- (28) EL: - *Χριστός Ανέστη!*
 - *Αληθώς ο Κύριος!*
EN: - *Christ is risen!*
 - *Truly He is risen!*
SP: - *¡Cristo ha resucitado!*
 - *¡En verdad ha resucitado!*

As far as the partial equivalents are concerned, they present a higher frequency. However, their precision is strongly depended on the description of the SIT which requires thorough details, as we can see in the following examples:

- (29) [take leave of someone in the evening]
EL: *Καλό απόγευμα!*

EN: *Good night!*
 SP: ¡*Buenas tardes!*

There were many cases of zero equivalents as well. In these cases the translation equivalence was not provided, as for example in:

- (30) [greet someone on the first day of the month]
 EL: *Καλό μήνα!*
 EN: lit. *Good month!*
 SP: lit. ¡*Buen mes!*
- (31) [to someone who got a haircut]
 EL: *Με γεια το κόψεμα!*
 EN: lit. *With health the new haircut!*
 SP: lit. ¡*Con salud el nuevo corte de pelo!*

5. Applications of pragmatemes

The systematic lexicographical processing of pragmatemes is oriented towards two main directions: (i) towards the language learning and (ii) towards the human and machine translation.

5.1 PragmaDiG and language learning

On the one hand, foreign language learners are in contact with pragmatemes from the beginning to advanced language proficiency. We could say that almost any introductory foreign language course begins with the common greetings. It is not a coincidence that A1 Level foreign language students on the “Common European Framework of Reference for Languages” should know how to introduce themselves (CEFR). It is also not coincidental that the fluent use of phrasemes similar to native speakers is the ultimate goal of foreign language learners, as Wray and Fitzpatrick (2008) mention.

On the other hand, the pedagogical significance of the dictionary use to foreign language learning is pointed out by Kojic-Sabo & Lightbown (1999), Knight (1994), Atkins & Varantola (1997) and Luppescu and Day (1993) among others. Thus, the PragmaDiG should assist in meeting the dictionary needs of foreign language learners. However, the pedagogical role that the PragmaDiG may play for native speakers as well should not be underestimated, especially within the frame of a genre-based approach to language learning. The communicative situation SIT constitutes the vinculum between pragmatemes and the genre-based approach, which is based on the “Systemic Functional Theory” developed by Halliday (1994) who links language closely to its contexts of use that are associated with the situational features of the field, mode and tenor (Halliday, 1978). These three values that define Halliday’s situational context correspond to the information provided in the PragmaDiG in the SIT and in the diasystematics of the microstructure.

The PragmaDiG within the frame of a genre-based approach could be a useful tool for the execution of queries regarding specific patterns to a certain text genre according to a series of criteria. For example, PragmaDiG users can find the appropriate pragmateme to close a formal letter. First, they would define the speech act (*take leave*). Then, they would specify the communicative situation SIT ([*in a letter*]). Finally, they would define the diasystematics, and especially, in this case, the diaphasic mark “formal” in order to come to the use of the pragmateme, i.e., *Με εκτίμηση* {*First name Surname*} (EN: *Yours faithfully* {*First name Surname*}, SP: *Atentamente* {*First name Surname*}).

5.2 PragmaDiG and translation

Apart from the pedagogical use PragmaDiG it is also considered to be of a great utility in the area of machine and human translation.

On the one hand, the structure of the PragmaDiG is built on foundations of the machine translation as it was compiled according to the *Dictionaries for Pragmatemes* of Blanco (to appear), which traces its roots to the *Monolingual Coordinated Dictionaries* (Blanco, 2001). The last lexicographical model is originally designated for automatic translation as it accurately provides the translation equivalence in other languages following a linear procedure of the information of the microstructure.

On the other hand, the incorporation of the PragmaDiG in an explicative and combinatory dictionary type is considered to be a useful tool for human translators. Translators are to be able to produce texts in L2 as all the translation aspects -including the thorny issue of the cultural aspect- are to be accessible and manageable in an active monofunctional dictionary.

6. Conclusions

In this paper the specific theoretical framework of pragmatemes has been described and their lexicographical treatment has been presented. In addition, applications of the Greek Pragmatemes Dictionary (PragmaDiG) to language learning and to human and machine translation have been discussed, laying ground for future work on Greek pragmatemes.

Future work will mainly focus on the enrichment of the macrostructure and the microstructure of the PragmaDiG. As far as the applications of PragmaDiG is concerned, the pedagogical dimension of PragmaDiG will be pointed out, especially within the frame of the genre-based approach to language teaching-learning.

THE PREVERB ΞΕ- IN STANDARD MODERN GREEK AND IN MODERN GREEK DIALECTS

Georgios Papanastassiou

Aristotle University of Thessaloniki, Greece

papana@lit.auth.gr

ABSTRACT

This paper aims at reviewing the formation of the Modern Greek preverb ξε-, in the various forms it appears in Standard Modern Greek and in Greek dialects (ξε-, ξ-, ξη-, ξι-, ξα-, etc.), exploring thus how it detached itself from the Ancient Greek ἐκ-, which was not the case with other Modern Greek preverbs (e.g. απο- < AGk ἄπο-, ἀνα- < AGk ἀνα-, etc.). This process is examined in combination with the meanings of the preverb in Modern Greek and its dialects.

1. Introduction

The Modern Greek preverb ξε- was the object of study for many linguists, both older and contemporary ones, obviously because of its especially interesting formation, as it is an element with Ancient Greek etymology but with a different form and different functions compared to its ancient ancestor.

2. Productivity

The preverb ξε- is always a bound morpheme,¹ added to substantives, e.g. ξεψαχνίζω, ξεζουμίζω, ξεκοκαλίζω, to adjectives, e.g. ξεχερσώνω, and to verbs, e.g. ξεκολλώ, ξεκουμπώνω, ξεβιδώνω. Its denominative character is indicated by cases like ξεφωνίζω, where there is no *φωνίζω. According to Tzitzilis (forth.), verbs like ξεστραβώνω, ξεθολώνω, that could be considered either denominatives or deverbatives, must come from verbs and not from adjectives.

Symeonidou-Christidou (1982) distinguishes the verbs with ξε- according to whether (1) their base is autonomous, with two groups (a) privatives (e.g. ξεντύνω – ντύνω) and (b) intensives (e.g. ξεγελώ – γελώ), (2) their base is not autonomous (e.g. ξεζουμίζω), or (3) they coexist with verbs of the learned tradition containing the preverb εκ- (e.g. ξεκινώ – εκκινώ).

3. Forms and formation

The formation of ξε- is described by Chatzidakis (1905, 31): “The [...] extension of the augment (ε) to the present tense can be seen in other verbs too, i.e. those starting with ξε, such as ξεκάνω, ξεχωρίζω, etc., which are wrongly believed to have preserved ἐξ in its inverse form [...]. There is no doubt that the evolution was as follows: the old forms were ἐκφεύγω ἐξέφευγον ἐξέφυγον, ἐξετύλισσον ἐκτυλίσσω, ἐξεκίνουν ἐκκινῶ, etc. [...]. After the use of ἐκ became restricted and its ἐξ form fell into misuse, there was no longer any sufficient similarity between ἐκκινῶ and ἐξεκίνουν and the like [...], and the initial ε of the form ἐξεκίνουν was perceived as the augment, which could be removed in order to form the present stem; just like in simple verbs, ἐφίλουν φιλῶ, the same applied to ἐξεκίνουν ξεκινῶ (my translation).” Therefore, a necessary condition for the creation of the form ξε- was that the Ancient Greek preverb had the form ἐξ- before a vowel, i.e. before the vowel of the verbal augment, and that this form was clearly differentiated from ἐκ-, which appeared before consonants, while the creation of

1. See *inter alia* Ralli (2003, 119): “[...] kse- appears only in clusters/composites and never as an independent word”.

the Modern Greek preverb was also influenced by the fact that the initial vowel of the form $\acute{\epsilon}\xi$ -, which appeared before the (internal) augment ϵ -, was taken to be an augment.

The phonetic conditions that resulted in the autonomy of the preverb $\xi\epsilon$ - are examined by Tzitzilis (forth.), who accepts that words with the AGk preverb $\acute{\epsilon}\kappa$ -/ $\acute{\epsilon}\xi$ - are represented in Modern Greek in three ways: (a) There are those beginning with a vowel in which the allomorph $\acute{\epsilon}\xi$ - appears for phonetic reasons, e.g. $\acute{\epsilon}\xi\alpha\phi\alpha\nu\acute{\iota}\zeta\omega$, where the preverb is preserved without phonetic (except sometimes the elimination of the initial vowel) differentiations; (b) there are verbs beginning with a consonant, where the preverb appears either with the form $\acute{\epsilon}\kappa$ - or with usual phonetic differentiations, e.g. $\acute{\epsilon}\kappa\beta\alpha\acute{\iota}\nu\omega > \beta\gamma\alpha\acute{\iota}\nu\omega$; in some of the verbs of these two categories no semantic change has occurred; and any semantic changes are not related to the presence of the preverb; (c) finally, there is a third category of verbs with $\xi\epsilon$ -, derived from AGk verbs beginning with a consonant, e.g. $\acute{\epsilon}\kappa\kappa\iota\nu\tilde{\omega} > \xi\epsilon\kappa\iota\nu\tilde{\omega}$.

The form $\xi\epsilon$ - is attested in Medieval Greek, e.g. $\xi\epsilon\beta\alpha\acute{\iota}\nu\omega$ (Prodrom.), $\xi\epsilon\gamma\delta\acute{\epsilon}\rho\nu\omega$ (Georgil.), $\xi\epsilon\gamma\upsilon\rho\acute{\iota}\zeta\omega$ (Imp.), etc. Besides, Modern Greek (DSMG s.v. $\xi\epsilon$ -) also uses the form ξ - before a vowel, especially before [a], in words like $\xi\alpha\rho\mu\acute{\alpha}\tau\omega\tau\omicron\varsigma$ 'unarmed' and $\xi\alpha\rho\mu\upsilon\rho\acute{\iota}\zeta\omega$ 'to remove the salt'. The creation of the form ξ - goes back to Medieval Greek, when the old form $\acute{\epsilon}\xi$ - lost its initial [e] before a vowel, e.g. Med. Greek $\acute{\epsilon}\xi\alpha\rho\mu\acute{\alpha}\tau\omega\tau\omicron\varsigma > \xi\alpha\rho\mu\acute{\alpha}\tau\omega\tau\omicron\varsigma$. But in many Modern Greek derivatives the already autonomous form ξ -, derived from $\xi\epsilon$ -, added to words beginning with a vowel, e.g. $\xi\alpha\rho\mu\upsilon\rho\acute{\iota}\zeta\omega$ (where no form $*\acute{\epsilon}\xi\alpha\rho\mu\upsilon\rho\acute{\iota}\zeta\omega$ / $*\acute{\epsilon}\xi\alpha\lambda\mu\upsilon\rho\acute{\iota}\zeta\omega$ is attested), formed as $\xi\epsilon$ - $\alpha\rho\mu\upsilon\rho\acute{\iota}\zeta\omega > *\xi\alpha\rho\mu\upsilon\rho\acute{\iota}\zeta\omega > \xi\alpha\rho\mu\upsilon\rho\acute{\iota}\zeta\omega$. Words with ξ -, however, are harder for speakers to analyse, as the preverb only consists of two consonants, [ks].

Modern Greek dialects present more complicated and, therefore, more interesting phenomena.

(1) The two forms, $\xi\epsilon$ - before consonant and ξ - before vowel, appear in the majority of the Greek dialects. Just to give a few examples: with the form $\xi\epsilon$ -, e.g. $\xi\epsilon\gamma\iota\delta\acute{\iota}\zeta\omega$ 'to stop tending goats', $\xi\epsilon\mu\alpha\zeta\acute{\epsilon}\nu\omega$ 'to finish picking up', $\xi\epsilon\mu\omicron\upsilon\tau\acute{\rho}\iota\zeta\omega$ 'to show one's face, to put one's nose out', $\xi\epsilon\eta\sigma\tau\iota\kappa\acute{\omega}\nu\omicron\mu\alpha\iota$ 'to not have eaten at all', $\xi\epsilon\psi\alpha\rho\acute{\iota}\zeta\omega$ 'to remove the fish from the net'. Also in archaisms (Andriotis 1974): form $\xi\epsilon$ -, e.g. $\xi\epsilon\beta\alpha\acute{\iota}\nu\omega$ (Pontos), $\xi\epsilon\beta\alpha\acute{\iota}\nu$ - $\nu\omega$ (Cyprus) < $\acute{\epsilon}\kappa\beta\alpha\acute{\iota}\nu\omega$ (cf. $\sigma\epsilon\beta\alpha\acute{\iota}\nu\omega < \epsilon\iota\sigma\beta\alpha\acute{\iota}\nu\omega$), $\xi\epsilon\kappa\alpha\lambda\lambda\acute{\upsilon}\nu\omega$ (E Crete) < $\acute{\epsilon}\kappa\kappa\alpha\lambda\lambda\acute{\upsilon}\nu\omega$, $\xi\epsilon\delta\omicron\upsilon\kappa$ 'ούμενε (Tsakonia) < $\acute{\epsilon}\kappa\delta\acute{\iota}\delta\omicron\mu\alpha\iota$, $\xi\epsilon\theta\epsilon\rho\mu\acute{\iota}\zeta\omega$ (Chios) < $\acute{\epsilon}\kappa\theta\epsilon\rho\mu\acute{\iota}\zeta\omega$, $\xi\epsilon\mu\omicron\upsilon\sigma\kappa\epsilon\lambda$ - $\lambda\acute{\iota}\zeta\omega$ (Chalce), $\xi\epsilon\mu\omicron\upsilon\sigma\kappa\iota\lambda$ - $\lambda\acute{\iota}\zeta\omega$ (Rhodes) < $*\acute{\epsilon}\kappa\mu\alpha\sigma\chi\alpha\lambda\acute{\iota}\zeta\omega$, $\xi\epsilon\gamma\lambda\upsilon\tau\rho\acute{\omega}\nu\omega$ (Epirus) < $\acute{\epsilon}\kappa\lambda\upsilon\tau\rho\tilde{\upsilon}\mu\alpha\iota$, $\xi\epsilon\eta\kappa\rho\acute{\omega}\nu\omega$ (Peloponnese) < $\acute{\epsilon}\kappa\eta\kappa\rho\tilde{\omega}$, $\xi\epsilon\pi\nu\acute{\epsilon}\upsilon\gamma\omega$ (Thera) < $\acute{\epsilon}\kappa\pi\nu\acute{\epsilon}\omega$, $\xi\epsilon\pi\upsilon\rho\acute{\iota}\zeta\omega$ (W Crete) < $\acute{\epsilon}\kappa\pi\upsilon\rho\acute{\iota}\zeta\omega$, $\xi\epsilon\theta\rho\acute{\epsilon}\beta\omicron\upsilon$ (Skyros) < $\acute{\epsilon}\kappa\tau\rho\acute{\epsilon}\phi\omega$, etc. In Calabria we find the form $\sigma\epsilon$ - (< $\xi\epsilon$ < $\acute{\epsilon}\kappa$ -), e.g. $\sigma\epsilon\beta\alpha\acute{\iota}\nu$ - $\nu\omega$ (Calabria) < $\acute{\epsilon}\kappa\beta\alpha\acute{\iota}\nu\omega$, and in Tsakonia the form $\tau\sigma\iota$ -, e.g. $\tau\sigma\acute{\iota}\chi\upsilon\mu\alpha$ < $\acute{\epsilon}\xi\acute{\epsilon}\chi\upsilon\mu\alpha$ (cf. $\acute{\epsilon}\kappa\chi\upsilon\mu\alpha$). Words with the form ξ -, e.g. $\xi\alpha\gamma\kappa\omega\nu\acute{\iota}\zeta\omega$ (Carpathos), $\xi\alpha\gamma\omega\nu\acute{\iota}\zeta\omega$ (Syme, Thera) < $\acute{\epsilon}\xi\alpha\gamma\kappa\omega\nu\acute{\iota}\zeta\omega$, $\xi\alpha\gamma\omicron\rho\acute{\alpha}\zeta\omega$ (in many places) < $\acute{\epsilon}\xi\alpha\gamma\omicron\rho\acute{\alpha}\zeta\omega$, are also archaisms, but they are irrelevant for the purpose of examining the evolution of $\xi\epsilon$ -. Occasionally the form $\xi\epsilon$ - extended to words beginning with a vowel, e.g. $\xi\epsilon\sigma\tau\epsilon\rho\acute{\iota}\alpha$, $\xi\epsilon\gamma\kappa\alpha\theta\acute{\iota}\zeta\omega$, $\xi\epsilon\phi\epsilon\nu\tau\acute{\epsilon}\upsilon\omega$, etc. (Chatzidakis 1915, 10).

(2) In Cyprus, before consonants the preverb appears either as $\xi\epsilon$ - or as $\xi\eta$ -, the latter being more frequent, e.g. $\xi\eta\beta\alpha\rho\kappa\acute{\alpha}\rho\omega$ 'to disembark, to go ashore' and $\xi\eta\beta\alpha\rho\kappa\acute{\alpha}\rho\omega$, $\xi\eta\beta\omicron\tau\alpha\nu\acute{\iota}\zeta\omega$, $\xi\eta\gamma\tau\acute{\epsilon}\rho\nu\omega$, $\xi\eta\delta\kappa\acute{\iota}\omega\chi\omega\nu$, $\xi\eta\zeta\acute{\epsilon}\upsilon\kappa\omega$ and $\xi\eta\zeta\acute{\epsilon}\upsilon\kappa\omega$, $\xi\eta\eta\tau\eta\lambda\tilde{\omega}$ 'to pump out, to drain', $\xi\eta\pi\alpha\gamma\acute{\iota}\alpha\zeta\omega$, etc. The form $\xi\eta$ - is also found in archaisms, e.g. $\xi\eta\beta\alpha\acute{\iota}\nu$ - $\nu\omega$ < $\acute{\epsilon}\kappa\beta\alpha\acute{\iota}\nu\omega$, $\xi\eta\zeta\eta\tau\tilde{\omega}$ < $\acute{\epsilon}\kappa\zeta\eta\tau\tilde{\omega}$, $\xi\eta\lambda\epsilon\acute{\iota}\beta\kappa\omega$ < $\acute{\epsilon}\xi\alpha\lambda\epsilon\acute{\iota}\phi\omega$, etc. Many words with $\xi\eta$ - are also found in the Peloponnese, e.g. $\xi\acute{\eta}\sigma\kappa\epsilon\pi\omicron\varsigma$, $\xi\acute{\eta}\sigma\tau\rho\omega\gamma\omicron\varsigma$, $\xi\eta\phi\omicron\rho\tau\acute{\omega}\nu\omega$ (privatives), much fewer in Megara, e.g. $\xi\eta\zeta\acute{\omega}\nu\alpha\tau\omicron\varsigma$ and $\xi\epsilon\zeta\acute{\omega}\nu\alpha\tau\omicron\varsigma$, $\xi\eta\gamma\upsilon\rho\iota\sigma\tau\acute{\alpha}\rho\iota$, and very few in the Ionian Islands, e.g. $\xi\eta\mu\upsilon\tau\acute{\alpha}\omega$ (Zakynthos). It is written with an < η > and it is not related to the homophone $\xi\iota$ - of the Greek Northern Dialects, which will be examined below. The form $\xi\eta$ - is already attested in Medieval Greek, e.g. $(\epsilon)\xi\eta\beta\alpha\acute{\iota}\nu\omega$ (Belth.), $\epsilon\xi\acute{\eta}\beta\eta\kappa\alpha$ (Imp.), $(\epsilon)\xi\acute{\eta}\beta\eta\gamma$ (Chron. Mor.), $\epsilon\xi\eta\beta\gamma\alpha\acute{\iota}\nu\omega$ (Poulol.), $\epsilon\xi\eta\kappa\alpha\mu\acute{\pi}\iota\zeta\omega$ (Physiolog.), $\xi\acute{\eta}\kappa\alpha\mu\pi\alpha$ (Mach.), $(\epsilon)\xi\eta\kappa\lambda\eta\rho\acute{\omega}\nu\omega$ (Assiz.), $\epsilon\xi\eta\kappa\omicron\upsilon\mu\iota\sigma\alpha$ (Pigas), $\xi\eta\pi\alpha\rho\theta\epsilon\nu\acute{\epsilon}\upsilon\omega$ (Assiz.), $\xi\eta\pi\lambda\epsilon\rho\acute{\omega}\nu\omega$ (Assiz.), etc. $\Xi\eta$ - was formed in a similar way as $\xi\epsilon$ -, i.e. in verbs which began with a vowel and whose internal augment had the form [i], e.g. $\acute{\epsilon}\xi\alpha\gamma\omicron\rho\acute{\alpha}\zeta\omega$ – $\acute{\epsilon}\xi\eta\gamma\omicron\rho\acute{\alpha}\sigma\alpha$, $\acute{\epsilon}\xi\epsilon\gamma\epsilon\acute{\iota}\rho\omega$ – $\acute{\epsilon}\xi\acute{\eta}\gamma\epsilon\acute{\iota}\rho\alpha$, $\acute{\epsilon}\xi\epsilon\lambda\alpha\acute{\upsilon}\nu\omega$ – $\acute{\epsilon}\xi\acute{\eta}\lambda\alpha\sigma\alpha$ etc., the interpretation of the initial $\acute{\epsilon}$ - as a syllabic augment resulted in the creation of forms like $\acute{\epsilon}\xi\eta\gamma\omicron\rho\acute{\alpha}\sigma\alpha > \xi\eta\gamma\omicron\rho\acute{\alpha}\zeta\omega$, etc.

(3) In the Northern Dialects the expected form before a consonant is $\xi\iota$ - when the preverb is unstressed and $\xi\acute{\epsilon}$ - when it is stressed, e.g. $\xi\iota\gamma\rho\acute{\alpha}\phi\omicron\upsilon$ (Pieria), $\xi\iota\delta\iota\alpha\lambda\acute{\epsilon}\gamma\omicron\upsilon$ (Kozani), $\xi\iota\zeta\acute{\omega}\nu\omicron\upsilon\mu\iota$ (Kozani), $\xi\iota\theta'\lambda\upsilon\kappa\acute{\omega}\nu\omicron\upsilon$ (Pieria), $\xi\acute{\epsilon}\gamma\eta\nu\omicron\iota\alpha\sigma\tau\omicron\upsilon\varsigma$ (Pieria), $\xi\acute{\epsilon}\pi\lambda\iota\kappa\omicron\upsilon\varsigma$ (Serres), $\xi\acute{\epsilon}\pi\upsilon\rho\omicron\upsilon\varsigma$ (Serres), $\xi\acute{\epsilon}\sigma\kappa\iota\pi\alpha$ (adv., Kozani), etc. In archaisms, e.g. $\xi\iota\mu\alpha\rho\gamma\acute{\omega}\nu\omicron\upsilon$ (Imbros) < $\acute{\epsilon}\kappa\mu\alpha\rho\gamma\tilde{\omega}$, $\xi\iota\theta\acute{\epsilon}\rho\omicron\upsilon\mu\alpha$ (N Thrace) < $*\acute{\epsilon}\kappa\theta\acute{\upsilon}\rho\omega\mu\alpha$, $\xi\iota\mu\omicron\sigma\kappa\iota\lambda\acute{\iota}\zeta\omicron\upsilon$ (Imbros) < $*\acute{\epsilon}\kappa\mu\alpha\sigma\chi\alpha\lambda\acute{\iota}\zeta\omicron\upsilon$, etc.

An important peculiarity of the Northern Dialects² which begs for interpretation is the appearance of a new form ξ(α)-. There are many examples: ξαβασκαίνου (priv.) (Naoussa), ξάγναντου (intens.) (Veroia), ξαγουράζου (intens.) (Pieria), ξαγουρνώ (intens.) (Pieria), ξαγραδίζου (intens.) (Rumelia), ξάγρους ‘unripenish’ (a little) (Serres), ξαδγάζου (intens.) (Pelion,³ Serres), ξαδραλίζουμι (priv.) (Naoussa, Pieria), ξάκλουστους (priv.) (Pieria), ξακόλλ’ τους (priv.) (Pieria), ξακουλνώ (priv.) (Naoussa, Pieria, Rumelia, Serres), ξακουνάζου (priv.) (Pieria), ξακούουμι (intens.) (Serres), ξακουσμένους (intens.) (Pieria), ξακουστός (intens.) (Pieria, Serres), ξακρίδ’ (intens.) (Pieria), ξακρίζου (intens.) (Germa, Kozani, Pelion, Serres), ξαλαφραίνου (intens.) (Naoussa), ξαλαφρώνου (intens.) (Naoussa, Pieria), ξαλέθου (end) (Pelion), ξαλησιμοννών (intens.) (Naoussa), ξαλλάζου (intens.) (Kozani, Naoussa, Serres), ξαλουνίζου (end) (Pelion), ξαμουλάου (intens.) (Pelion), ξαμπασκαλίζου (removal) (Serres), ξανάβου (intens.) (Serres), ξανάλλαγους (priv.) (Serres), ξανάλατους (priv.) (Pelion), ξανασαίνου (intens.) (Pelion, Serres), ξανασέρνου (intens.) (Kozani), ξανάχουμα (priv.) (Veroia, Kozani, Pieria), ξαναχώνου (priv.) (Kozani, Pieria), ξανδρουπχάζου (priv.) (Kozani, Naoussa, Pieria), ξανέβγαλτους (priv.) (Pieria), ξανένδρουπους (priv.) (Kozani, Pieria, Rumelia), ξανοίγου (intens.) (Kozani, Naoussa, Pelion, Pieria, Serres), ξανόριχτους (priv.) (Pelion), ξανουστίζου (priv.) (Pelion), ξαντριζου (removal) (Serres), ξαντόνου (priv.) (Naoussa), ξαπιρνώ (intens.) (Serres), ξαπλώνου (intens.) (Naoussa), ξαπουλνώ (intens.) (Kozani, Naoussa, Serres), ξαπουμένου (intens.) (Kozani, Pieria), ξαπουμνήσκου (intens.) (Naoussa), ξαπουμνήσκου (intens.) (Serres), ξαπουστένου (intens.) (Kozani, Naoussa, Pelion, Pieria, Serres), ξαπουστέλνου (intens.) (Serres), ξαπουχτώ (Kozani), ξαραδγάζου (intens.) (Kozani, Pieria, Serres), ξαραθμώ (intens.) (Kozani, Pieria), ξαραθμού (intens.) (Rumelia), ξαραθυμώ (intens.) (Naoussa), ξαραχιάζου (removal) (Naoussa), ξαριθμώ (priv.) (Pieria), ξαρματώνου (priv.) (Pelion), ξαρμινάζου (priv.) (Pieria), ξαρμυραίνου (priv.) (Serres), ξαρμυρίζου (priv.) (Pelion, Serres), ξαρρουσταίνου (priv.) (Serres), ξαρρουστώ (priv.) (Serres), ξασλάρουτους (priv.) (Pieria), ξασπρίζου (intens.) (Pelion), ξασπρούλαβους (intens.) (Kozani), ξάσπρους (intens.) (Serres), ξάστιπου (intens.) (Veroia, Pelion), ξαστριγά (intens.) (Pieria, Serres), ξαστριώνου (intens.) (Pieria), ξαστουχώ (intens.) (Kozani, Pieria, Rumelia, Serres), ξάστρου (intens.) (Naoussa), ξάσφιχτους (priv.) (Pieria), ξατμίζουμι (intens.) (Serres), ξαφανίζου (intens.) (Pieria), ξαφρίζου (intens.) (Germa, Kozani, Pelion). Beside these forms, in some cases there is the corresponding ξι- form, e.g. ξικουλνώ (Naoussa), ξιπιρνώ (Serres), ξισλάρουτους (Pieria), ξιστριγά (Pieria, Serres), ξιστριώνου (Pieria), etc.

The following considerations come into play in order to interpret the form ξα-: The existence of [ʃ] and not [s] in the preverb should be attributed to the existence of a semivowel, which was lost after palatalising the previous consonant. This means that in these Northern Dialects the regular form ξι- before consonants was extended to words beginning with a vowel, i.e. before [a]. This process must be understood as follows: just like the Standard Modern Greek form ξε- is added today to partly opportunistic yet surely loose formations like ξεαγχώνομαι, with the full form ξε- and not with the form ξ- expected before [a], in many Northern Dialects the form ξι- was added to words beginning with a vowel, in which the vowel /i/ easily turned to semivowel and then palatalised the preceding [s], resulting in the form ξα-.

The extension of ξι- to words beginning with a vowel is found:

(a) in privative adjectives with the preverb α-, e.g. άκλουστος – *ξιάκλουστους > ξάκλουστους, ασλάρουτους ‘uncared-for, untidy’ – *ξιασλάρουστους > ξασλάρουστους but also ξισλάρουστους < ξι- + σλαρώ(νου) -τους, ακόλλ’ τους – *ξιακόλλ’ τους > ξακόλλ’ τους, etc. In these cases the privative preverb ξι- (< ξε-) was added in order to reinforce the privative meaning of the adjectives with the preverb α-.

(b) in other words, e.g. αγραδίζου – *ξιαγραδίζου > ξαγραδίζου, άγρους ‘unripe’ – *ξιάγρους > ξάγρους, αδγάζου – *ξιαδγάζου > ξαδγάζου, αδραλίζουμι – *ξιαδραλίζουμι > ξαδραλίζουμι, ακούουμι – *ξιακούουμι > ξακούουμι, αλαφρώνου – *ξιαλαφρώνου > ξαλαφρώνου, αλέθου – *ξιαλέθου > ξαλέθου, etc. In these cases the preverb ξι- (< ξε-) is usually privative or intensive.

In the case of privative adjectives, a new preverb ξα- was created as a result of the combination of the preverb ξι- with the privative α-. The prefixation of ξα- is related to the fact that it was contrasted with simple adjectives, forming pairs of the type κουλλ’ ττός – ξακόλλ’ τους etc., or with the corresponding verbs, forming pairs of the type κλώθου – ξάκλουστους, etc. When the privative prefix was av- before a vowel, the new preverb took the form ξαν-, e.g. ξανάλλαγους, ξανάλατους,

2. For the Northern dialects, the material comes from Eastern Rumelia (Albanoudis 2009), Veroia (Svarnopoulos 1973), Germa in the Prefecture of Kastoria (Georgiou 1962), Kozani (Dinas 2005), Naoussa (Apostolou 2007), Pelion (Liapis 1996), Pieria (Douga-Papadopoulou & Tzitzilis 2006) and Serres (Paschaloudis 2000).

3. In Pelion, according to Liapis (1996), most of the words are also attested with a non-palatalised [s].

ξανόριχτους. In the case of other words, particularly verbs, the combination of the preverb ξ- with the initial α-, which sometimes was prothetic, resulted in the prefixation of the form ξα-, insofar as the prothetic vowel is unstable, e.g. (α)βασκαίνου – ξαβασκαίνου, (α)κουλνώ – ξακουλνώ, (α)λησιμουνώ – ξαλησιμουνώ, etc. Thus, the reanalysis of ξα- as a preverb was affected by the fact that in many of the aforementioned words α- was either a morphological element or its presence was not obligatory. Before other initial vowels ξ- (< ξι-) was very rare, and the remaining conditions for it to acquire the character of a morphological element were missing. The [ʃ] of ξα- then extended to other words beginning with ξα-, e.g. ξάγναντου > ξάγναντου, ξαγουράζου > ξαγουράζου, ξακουσμένους > ξακουσμένους, ξακουστός > ξακουστός etc., this evolution being purely phonetic.⁴

(4) Finally, as regards the forms of the preverb, there are also words of AGk origin where the preverb ἐκ-/ἐξ- resulted in several phonetic effects in Standard Greek, especially in Greek dialects. For example, in verbs such as βγαίνω and βγάζω, the origin is: AGk ἐκβαίνω ‘to step out’ > *ἐγβαίνω > γβαίνω > βγαίνω· AGk ἐκβιβάζω ‘to make someone go, to go out’ > *εκβάζω (haplology [viva > va]) > *εγβάζω (assimilation [kv > gv > γv]) > *εβγάζω (metathesis [γv > vγ]) > βγάζω (elimination of the initial vowel). These words cannot be analysed, and this is also the case with many dialectal archaisms:

- εκ-, e.g. εκδημία (Chios) < ἐκδημία; εκπλύνω (Thera) < ἐκπλύνω; εκτέτε (Cappadocia) < ἐκτοτε;
- εξ-, before a vowel, e.g. εξαγκωνίζω (Cyprus) < ἐξαγκωνίζω; εξαιμάσσω (Chios) < ἐξαιμάσσω; εξαίρετε (Tsakonia) < ἐξαίρετος; εξαλείφω (Epirus etc.) < ἐξαλείφω;
- αφσ-, e.g. αφσαίφνη (Apulia) < ἐξαίφνης, with a characteristic phonetic treatment [ks] > [fs];
- εγ-, before a voiced consonant, e.g. εγβαίνω, εγβάλλω (Pontos) < ἐκβαίνω, ἐκβάλλω (and with metathesis εβγ-, e.g. ιβγατή [Macedonia, /i/ < /e/] < ἐκβατός, and with elimination of the initial vowel βγ-, e.g. βγάση [Thrace] < ἐκβασις, βγατό [Thrace, Lesbos, Chios] < ἐκβατός, cf. Standard Modern Greek βγαίνω, βγάζω < ἐκβαίνω, ἐκβάλλω; and αβγ-, e.g. αβγάλλω [Cyprus] < ἐκβάλλω, αβγατό [N Thrace] < ἐκβατός); εγδέχομαι (Cyprus, Chios) < ἐκδέχομαι· εγδίκηση (Tsakonia) < ἐκδίκησις; and before a voiceless consonant εχ-, e.g. έχτομος (Pontos) < ἐκτομος; εχτρέβω (Pontos) < ἐκτρέπω;
- (ε)γκ-, e.g. εγκλαβή (Rhodes) (and αγκ-, e.g. αγκλαβή [Nisyros, Rhodes, Samothrace, Syme], avg-, e.g. avgλαβή [Chalce]) < ἐκλαβή; εγουάδδω, ’γουαίν-νω (Calabria) < ἐκβάλλω, ἐκβαίνω;
- (ι)g-, e.g. (ι)γουαίν-νω, ’γουάλλου (Apulia) < ἐκβαίνω, ἐκβάλλω;
- εϊ-, e.g. εϊβαίνω (Pontos) < ἐκβαίνω;
- ογ-, e.g. ογβαίνω (Pontos) < ἐκβαίνω; ογδούρι (Carpathos) < ἐκδόριος;
- (α)χ-, e.g. αχπάνω (Pontos), χπαίνω (Pontos) < ἐκσπῶ;
- γ-, e.g. γβάλλω < ἐκβάλλω (Pontos); γδορά (Skyros), γδουρά (Peloponnese) < ἐκδορά; γδούρι (Thera), γδούρ’ (Euboea) < ἐκδόριος· γδέχομαι (Crete, Chios) < ἐκδέχομαι (and αγ-, e.g. αγδέχομαι [Cyprus] < ἐκδέχομαι; άγλαμπος [Calymnos, Rhodes, Telos] < ἐκλαμπος); γλακώ (Carpathos, Crete) < *ἐκλακῶ, γλουπίζω (Pontos) < ἐκλωπίζω; and before a voiceless consonant χ-, e.g. χταμπιούμαι (Kythnos), χταβιούμαι (Mykonos), χταμπιέμαι (Syros), χταβιέμαι (Kea), χταμπίζομαι (Siphnos), χταπίζομαι (Kea) < ἐκθαμβῶ; χτουπίζω (Pontos) < ἐκτοπίζω (and αχ-, e.g. άχτομος [Pontos] < ἐκτομος);

κ’-, representing a double consonant, resulting from ἐκκ-, e.g. κ’ρούνου (Tsakonia) < ἐκκρίνω.

These forms are not perceived as prefixes, not only because they are very rare in the dialects in which they appear, but also because in these dialects the corresponding form of the preposition is not attested as an independent morpheme, as shown by the comparison between the forms of the morpheme and of the preposition: the preposition has the forms εχ in Telos, ακ in Cyprus, αχ in Epirus, Cyprus, Macedonia and Pontos, α in Bithynia, Thera, Calymnos and Naxos, οκ in Carpathos, οχ in Zakynthos, Epirus, Cephalonia, Peloponnese (Andriotis 1974, s.v. ἐκ) and on the other hand forms like άτσε, αττσε, ασε in Calabria, αφς, αφς, εφς, αφσε, αφτσε, ατσε in Apulia, ας in Apulia, Cappadocia, Pontos and Chios (Andriotis 1974, s.v. ἐξ).

4. Expanded forms

In some cases the preverb ξε- or one of its forms (ξ(α)-, ξη- etc.) is added to an already prefixed verb:

(1a) with the privative prefix απο-, e.g. ξηποράφκω, ξηποσσεπάζομαι, ξηποτυλίω ‘to unwind, unwrap’ (Cyprus), reinforced by the privative ξε- (in Cyprus ξη-), resulting in the form ξαπο- (in Cyprus ξηπο-), with a privative meaning.

4. It should be stressed that the form ξα- found in many Northern dialects is not universal, e.g. it is not found in Lesbos.

(1b) with the intensive απο- (& > απου-), e.g. ξαπουμένου (Kozani, Pieria), ξαπουμινήσκου (Naoussa), ξαπουμνήσκου (Serres), ξαπουστέλνου (Serres), reinforced with the intensive ξε-, resulting in the form ξαπο- with an intensive meaning.

(2) with ανα-, e.g. ξανασέρνου (intens.) (Kozani), ξαναχώνου (priv.) (Kozani, Pieria).

5. Meanings

Regarding the identification of the meanings of the preverb, the review of the literature shows that there are many differences among scholars, though partly apparent ones. The ancient meanings of the preverb ἐκ- are largely preserved (Méndez Dosuna 1997), although it should be acknowledged that the boundaries between them have been blurred (Euthymiou 2002, 200).

Gardikas (1912, 170-73; cf. Chatzidakis 1915, 14) wrote about the meanings of the AGk ἐκ- and the Modern Gk ξε-, indicating six meanings: (a) ‘out’, e.g. ξεβλαστώνω, ξεστομίζω, (b) ‘removal or loss, or privative’, e.g. ξαφρίζω, ξαραχνιάζω, (c) ‘intensive’, e.g. ξεγδέρνω, (d) ‘the meaning denoted by the old ἐκ and ἀνά’, e.g. ξεδιπλώνω, ξεκουβαριάζω, (e) ‘forward or upward’, e.g. ξεφτυλλίζω, ξεμυτίζω, (f) ‘the meaning denoted by the old διά and δι- + ἐκ’, e.g. ξεχειμωνιάζω, ξεκαλοκαιριάζω.

Chatzidakis (1915, 10-11) identified eleven meanings of the preverb ξε-: (1) compounds, like ξεμανδρίζω = ‘to drive out of the fold’, ξεφαραγγώνω ‘to come out of the ravine’ etc., (2) compounds denoting the opposite of the above, like ξεκαμπίζω ‘to go out to the plain’, ξεπελαγιάζω, ξεραχνιάζω [...] etc., (3) compounds like ξαραχνιάζω, ξαρμυρίζω [...] ‘to remove the cobweb, the salt’ [...], (4) compounds like ξαστερώνει = ‘the stars appear’ [...], ξεφεγγαρώνει = ‘the moon rises’ [...], (5) compounds like ξεσμιλώνω ‘to dislocate or damage something with a chisel’, ξεπασσουλίζω ‘to move something with a pole’ [...], (6) ξαποσταινών, ξεδιαντρέπομαι [...] which are intensive, (7) other compounds, like [...] ξεβγατίζω, ξεδίδω etc., clearly denoting ‘out’, (8) other compounds denoting diminutive in some way, like ξεπλύνω, ξεπετώ, ξεσκαλίζω [...], (9) other compounds where the preverb annuls the meaning of the verb, ξεγράφω, ξεβάφω [...], (10) other compounds where εξ- ξε- seem to denote the end, ξεθερίζω, ξεσκολίζω = to finish harvest, school [...] and (11) other compounds denoting ‘spending time’, like ξεχειμωνιάζω, ξενοχτώ [...].

Euthymiou (2001, 210) accepts seven different meanings for Modern Greek ξε-: (1) undoing of an action,⁵ e.g. ξεντύνω, ξεκλειδώνω, (2) removal of an object, e.g. ξεφλουδίζω, ξεδοντιάζω, (3) intensification or completion, e.g. ξεκουφαίνω, ξετρελαίνω,⁶ (4) end of a state or quality, e.g. ξεμεθώ, and ξεκρύο, ξέπαπας (in stereotypical expressions), (5) spending a period of time, e.g. ξεχειμωνιάζω, (6) ‘out’, ‘outwards’, e.g. ξεπορτίζω, ξεσπιτώνω, (7) diminutive, e.g. ξεκλέβω, ξεγλιστρώ. She argues that for an important number of words built with the prefix ξε- and denoting removal, distancing or reversal, the semantic instruction of the prefix could be specified as a move away from some original reference point determined by the semantic properties of the base and by the nature of the arguments of the verbal derivative.

She summarises the semantic property of ξε- as follows: “The meanings of ‘out’, removal of an object from a container or a location at large, undoing of an action, end and intensification, they can all

5. With regard to the meaning of undoing, Euthymiou (2002, 201) states that “[...] unlike its ancestor, ξε- is extremely prolific in building words that denote undoing, whereas it builds much fewer words belonging to other semantic subgroups”. This meaning “is almost non-existent in ancient words with ἐκ- [...] identified less than ten words of this type and this suggests that the Ancient Greek ἐκ- most likely did not construct the meaning of undoing. Méndez Dosuna also mentions very few examples of this type: ἐξαλείφω, ἐκκολάπτω, ἐκκαλύπτω, ἐκχαλινώ and ἐκζηλώ. If one takes a closer look at the meaning of these words, whose bases denote placing something or causing a surface to change – and also at the meanings of ἐκλύφω, ἐκγράφω [...] – one detects the original meaning of removal. This meaning is clearer in the examples ἐκχαλινώ, ἐκζηλώ, where it is easier to detect the nominal base. I believe that these words denote primarily the meaning of removal, ‘removal of the bridle’, ‘removal of the nails’ and that this is the meaning which led to the meaning of undoing an action. It is highly likely that the large number of verbs denoting reversal which were created later with the prefix ξε- were modelled after words of this type” (my translation). (Euthymiou 2002, 201)

6. According to Euthymiou (2003, 525-26), intensification which is not combined with the notion of exceeding the limit is also denoted by words with the prefix ξε-: ξεγδέρνω, ξεσκίζω, ξεκαθαρίζω, ξεγυμνώνω, ξεμουρλαίνω, ξετρελαίνω. [...] Such words denote exiting an original state and entering a final one.

come under the umbrella of the meaning of exiting a space or a state. It suggests a move away from a starting point [...], which however presupposes the notion of inside (my translation)."⁷

Méndez Dosuna (1997, 587), having contributed very much to the semantic evolution of the preverb, refers to the distinction of the words with the Ancient Greek preverb ἐκ- > ἐξ- in two categories, and traces the role of semantics in the evolution εκ- > ξε-: "Eks- originally denoted an outward movement, separation or extraction: ekbaino: 'to step out', ekserkhomai 'to go, to come out', ekselauno: 'to drive away' [...]. Secondly, the prefix expressed the idea of completion, intensification (cf. E. out): ekkathairo: 'to clean thoroughly', eklouo: 'to wash out', ekpimple:mi 'to fill up' [...]. Alternatively, the notion of separation, extraction evolved into that of deprivation, removal, cancellation of a verbal state or action: eksoplizo: 'to disarm', eksaleipho: 'to wipe off, to obliterate', ekkalupto: 'to uncover' [...]. [...] in Medieval Greek [...] verbs compounded with eks- (ek-) split into two groups. One set of verbs follows the natural matter of course, i.e. they undergo fusion. Sound changes were permitted to apply regularly: e.g. ekbaino: > *egbaino: (voice assimilation) > *eyveno [...] > *yveno [...] > vjeno [...]. However, in a second set of verbs, eks- was reshaped into kse-: ksefevgo 'to run off', ksekovo 'to cut off', ksepleno 'to wash out' [...]."

Méndez Dosuna (1997, 590-93) also raises the question of whether "the fusion and non-fusion of eks- compounds [...] are dependent on the semantics of the prefix." As far as the basic meanings of the preverb is concerned, 'outward movement', 'intensification' and 'reversal', (1) "direction is one of the most salient components in a motion event [...]" and "lexical (amalgamated) expression of direction is indeed not infrequent", (2) "intensification will seldom be expressed lexically" and "reversal [is] most suitable for morphological encoding." "Fusion is especially frequent in the case of compounds where AGk eks- indicated an outward movement" and "morphotactically transparent kse- can express (often redundantly) an outward movement or separation. But this device has lost productivity. Unlike in Ancient Greek, one is no longer free to build compounds like *kse-trexo, *kse-kolimbo." "Intensifying kse- is not uncommon in Modern Greek, but its productivity remains low as well. [...] The semantic feebleness is conducive to morphosemantic opacity: ksevyazo 'to rinse' is hardly decomposable in kse- + vyazo 'to put out' [...]." "By contrast, when expressing reversal, a sense more suitable for morphological expression, the prefix kse- remains fully productive. [...]"

It is true that the discussion of whether the preverb ξε- has six, seven or eleven meanings is pointless, since (a) it has been accepted that the boundaries between them are unclear, and (b) it is known that more than one semantic nuances can come under one meaning. The two major semantic categories covered by ξε- are those referred to by Ralli (2003, 109-10): (a) privative (e.g. ξεπτόνω – πτόνω) and (b) intensive (e.g. ξεγελώ – γελώ).⁸

7. See Euthymiou (2001, 207). This is self-evident in the meaning of exiting a space, but it is also true in the rest of the meanings: "In the groups 'end of a state or quality' and 'undoing an action' again there is the meaning of exiting a state and moving into a new one: ξεμεθώ, ξεπαπάζ, ξελέω, ξεπτόνω. As Ralli (2001) rightly points out, ξε- builds the meaning of undoing only with verbs which denote completion, not state, process or accomplishment. [...] Less evident yet equally present – to our eyes – is the meaning of exit in words which denote intensification: ξεγδέρνω, ξεσκίζω/ξεκαθαρίζω [...] These words denote exiting an original state and entering a final one (or else its most extreme form). It is no coincidence that only in this group, as stated by Ralli (2001), is ξε- combined also with verbal bases which denote accomplishment: ξεπέφτω, ξεφεύγω. [...] Lastly, in the small group of words which are constructed with bases denoting "period of time", such as ξεκαλοκαιριάζω, ξεχειμωνιάζω, again there is the meaning of exiting the boundaries of a time period, of transition from one period of time to another or of moving away from the beginning of a time period towards its end." (Euthymiou 2002, 207, my translation)

8 Ralli studies ξε- in juxtaposition to ξανα- and παρα-: "As opposed to verbs with ksana-, the kse- and para- verbal formations do not show a consistent behaviour with respect to semantics. Firstly, there are occurrences where kse- or para- do not affect the aspectual properties and the argument structure of the verbal base. In that sense, they behave like ksana", e.g. κλειδώνω, ξεκλειδώνω. (Ralli 2003, 112) Ξε- reverses what the verb expresses and "productively combines with verbs denoting an accomplishment [...]. [...] kse- cannot be adjoined to verbs denoting an achievement". (Ralli 2003, 112) Ξε- also has an intensive meaning, e.g. ξεκαθαρίζω. "It is under the intensive meaning that kse- can combine with some verbs of achievement, and form verbs with a non-compositional, and highly lexicalized meaning, something that would not have been possible if kse- had a reversative meaning." (Ralli 2003, 114) She believes that ξε- is polysemic and that there are no two homonymic ξε-. (Ralli 2003, 115) "Structurally, kse- and para- behave as prefixes [...]". (Ralli 2003, 126) "Kse- and para- display a dual character, since they can assume an internal or an external role, while ksana- is used only as an external preverb". (Ralli 2003, 130) Karantzola & Giannouloupoulou (2000) recognise two meanings: (1) completion of the action denoted by the verbal base, which certain verbs preserve almost unchanged, as shown by the use of both the simple and the compound form (examples from Kartanos, χωρίσωμεν and εξεχώρισεν (82)), but other examples illustrate "the productivity of the meaning 'completion of the action', since ξε- preserves the

obvious meaning of εκ/εξ it is derived from, i.e. it expresses the notion of ‘outward motion’ and (2) the opposite of the meaning of the verbal base.

ANALYSING THE GREEK NATIONAL TOURISM ORGANISATION NEWSLETTER AS A NEW INTERNET GENRE

ABSTRACT

In the summer of 2010 the Greek National Tourism Organisation (GNTO) launched its first newsletter to promote the country as an attractive tourism destination. In this paper we examine the ways in which this promotional genre fulfils its communicative purposes. We analyse the structure of the newsletter, its form and functional value. Besides, the GNTO newsletter constitutes a new Internet genre. Therefore, text length, hypertextual linking, and text/image correlation are also taken into consideration. Finally, since the texts are written both in English and Greek we examine the way they are transferred from one language to another.

Keywords: newsletter, promotional genre, cybergenre/internet genre, multimodality, interactivity

0. Introduction

In July 2010 the Greek National Tourism Organisation put out its first Internet newsletter in an attempt to rebuild Greece's damaged image and to implement the country's overall brand strategy. The newsletter evidently holds a privileged position in the GNTO's website, being both the official voice of an institution responsible for creating attractive images of Greece for the local and for the international tourist market, and also an open channel of communication with people who plan to visit or have visited the country (having previously visited GNTO's website). On the basis of this observation, we can offer a rough description of the newsletter as a digital (or Internet) genre. Compared to common/traditional newsletters the GNTO's newsletter has a unique feature: it combines –or rather intermingles– information and/or evaluation, persuasion, details of special tourist destinations and suggestions to help potential visitors to enjoy these places. It is a non-commercial (culturally oriented) advertorial (Erjavec 2004) that can be classified as a new member of the promotional genre colony (Bhatia 2004). The dominant conative function of an Internet genre like this is based on multimodality and hypertextuality, the two structural properties of digital documents, referring to the variety and organisation of information respectively. Functionality in the sense of interactivity, the website-user interface potential, is the third characteristic of the GNTO's newsletter as a genre, which takes advantage of all social media to broaden communication with the targeted audience. Finally, evolution, being perceived as gradual integration of new verbal and visual formats, it is proved to be a standard tendency of the GNTO's newsletter from the beginning until now.

The aim of this paper is to consider the novelty of the GNTO's newsletter as an Internet genre and its prospective impact on its readership. More specifically, we will examine:

- how the online travel newsletter could be analysed in terms of its socio-cultural and textual conditions (i.e. communicative/rhetorical purpose(s), generic class membership, schematic structure, prevailing text types);
- how the multimodal assembly of verbal and visual constituents leads to a cohesive (and coherent) discourse pattern;
- the textual and hypertextual profile of the particular genre, in other words the statistically dominant lexico-grammatical features (textuality) and the repertoire of semantic relations between texts and the corresponding hypertexts (hypertextuality);
- the way(s) in which the author(s) of the GNTO's newsletters address(es) the intended audience to stimulate a desire to visit Greece.

1. Theoretical considerations

Analysing Internet genres (or cybergenres) at various levels (content, form, function, and evolution) is a demanding task because a group of methodological tools –both linguistic and non-linguistic– need to be used. We will, therefore, focus on a set of theoretical and typological proposals that are necessary to identify the GNTO’s newsletter as a new (i.e. multimodal, hypertextual, interactive) Internet genre.

Internet travel newsletters share with several other (addressee-oriented) genres a common communicative purpose which is *promotion* (of either information or goods and services in a local or global market). They all make up a “genre colony”. Bhatia’s (2004: 59-64) classification of promotional genres is the most comprehensive survey/description of a great number of discourse activities performed in the commodity and cultural market. Bhatia, in his study (see Figure 1):

a. Sets forth a hierarchy of ethnographic criteria to identify a wide range of promotional genres and subgenres and constructs a tree-like diagram pointing to similarities and differences between promotional genres/subgenres which are labelled, in a descending order, as genre colony > genre > subgenre, etc.

b. States that two controlling text-types (or rhetorical acts), information and evaluation –he prefers to call them “generic values”– “are used in various combinations (...) to give shape to (...) promotional genres”. Indeed, these textual sequences abound in our material, thus confirming that the GNTO’s newsletter is a member of a promotional genre colony.

Figure 1 Versatility in generic transcription
Adapted from Bhatia’s *Worlds of Written Discourse* (2004: 59)

c. Depicts the members of the colony (e.g. advertisements, sales promotion letters, grand proposals, book blurbs, company reports, travel brochures, etc.) as overlapping domains arranged on different clines “in terms of the degree and nature of appropriation of promotional elements” (p. 62, see Figure 2). Thus, he makes a distinction between primary and peripheral members of the colony. Advertorials, like the GNTTO’s newsletter, “are mixed genres, partly promotional, partly information-giving or opinion-giving”.

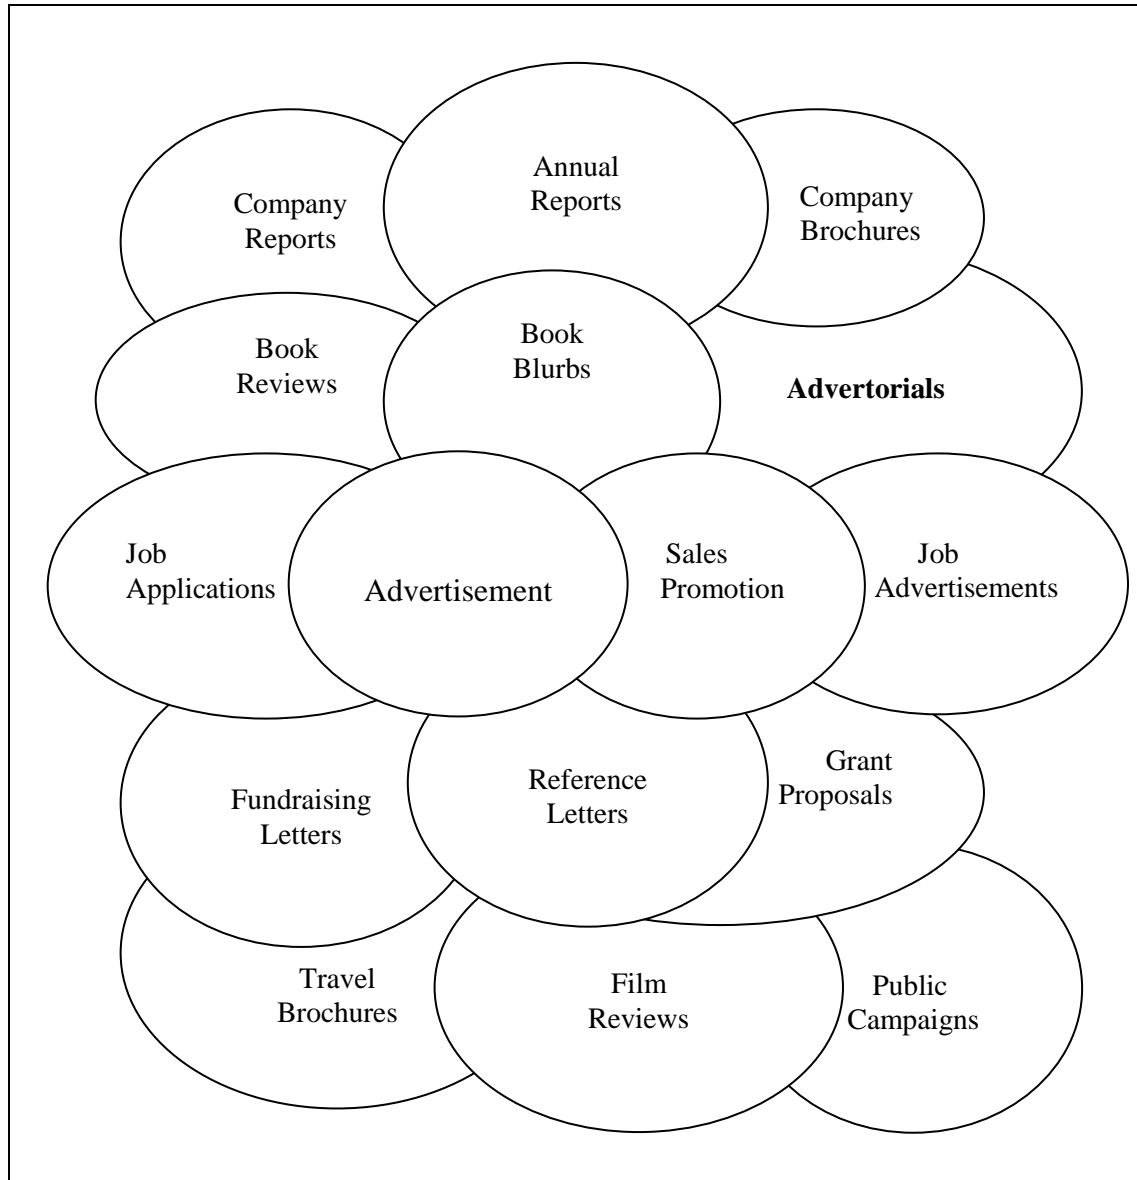

Figure 2 Colony of promotional genres
Adapted from Bhatia’s *Worlds of Written Discourse* (2004: 62)

We also need a model to describe the GNTTO’s newsletter in relation to its “mode of discourse”, the semiotic materiality of this particular genre. Shepherd & Watters (1998) invented the term *cybergenre* to indicate Internet genres and identified two classes of subgenres: *extant* and *novel* (see Figure 3). The first class comprises those based on genres existing in other media, such as paper and video, that have shifted to a digital form. When an already existing genre relocates in a computer environment, it is faithfully *replicated* in the initial stage, because does not completely take advantage of the potential of the new medium. Content and form remain almost the same (as, for instance, in the electronic edition of a newspaper). At a subsequent stage in the evolution, *variant* genres are emerged that fully exploit the capabilities of the new medium. That is the reason why these genres are characterised by multimodality (Kress 2010) and interactivity. Electronic news is a typical example of

variant genre, designed to fit in with the new medium. The second class (*novel cybergenres*) includes those wholly dependent on the new medium. They may come from extant genres (*emergent cybergenres*) or may be entirely new genres (*spontaneous cybergenres*). Obviously, the GNTO's newsletter is a novel emergent cybergenre.

Figure 3 Cybergenres

Finally, concerning hypertextuality and interactivity, mainly in the sense of hypertextual connectivity and coherence, we draw on Jucker's theoretical framework (2002) of "hypertextlinguistics". Particularly useful for the study of Internet newsletters are:

- the distinction between *interactivity* (the multilinear network of hypertextual structures) and *interaction* (the actual "conversation" between the reader and the hypertext);
- a typology of cohesive elements connecting a root text with a destination text (semantically filled links, semantically empty links, pop-up windows), and
- a typology of hypertexts on the basis of various pragmatic categories or textual sequences.

2. Visitgreece web team ethnography and general info

The first issue of the GNTO newsletter appeared in July 2010 (English version only). As already mentioned earlier, the Greek National Tourism Organisation produced its first newsletter in an attempt to create a fresh positive destination image by exploiting the opportunities offered by the Internet.

Figure 4 The GNTO newsletter

The visitgreece web team (staff working at the GNTO) consists of copy editors who write and proof the articles, web designers who design the layout, and social media experts who are responsible for distribution (i.e. creating a sign-up list, monitoring the number of recipients of the newsletter, calculating the number of Greek or foreign readers, etc.)

According to the monthly schedule, the newsletter goes online the first Thursday of every month, with 3-4 topics in English and in Greek. The topics are selected according to:

- (a) the time of year (November: olive harvesting; January: skiing, etc.),
- (b) tourist activities, in order to promote Greece as a year-round destination,
- (c) important cultural events (“Dimitria” in Thessaloniki), and so on.

The form of the newsletter has been redesigned since the first issue was launched. In particular, from December 2010 until now the following major changes have taken place:

- in the layout (December 2010): more vivid colours are used in line with Greece’s national colours, the title and teaser length has been decreased as well as the framing margins;
- in the content (January 2011): social media are introduced as a topic is chosen based on the response to a question posted on facebook;
- a follower is rewarded for their tweet with the best tweet being included in the newsletter, which has now become more interactive. Similarly, an article is sometimes presented for facebook fans based on their feedback.

Furthermore, in January 2011 two sections were added: an editorial section so that the Organisation could address readers more directly and a “special feature” where texts written by licensed tourist guides are presented. Additionally, every month those who receive the newsletter see an intriguing title in their inbox that invites them to click & read. Since May 2011 the newsletter has also included video clips (instead of a 4th topic) linked to the general topic of the month, e.g. when the topic was about summer holidays the video clip entitled SEASIDEINGREECE was selected.

3. The parts of the newsletter

The GNT0 newsletter consists of the following parts:

- (1) The header YOUINGREECE, which includes pictorial items, such as the signature line & logo used to focus the DESIRE on a certain brand.¹

Figure 5 The header

- (2) The subject. “Subject” is defined as the title of each newsletter received by the subscribers. It appears in their inbox and helps introduce them to the issue’s monthly topic (e.g. «Ιανουάριος 2011: Πάμε για σκι!», “June 2011: It’s a family affair!”, “May 2011: Summer? Greece of course. Where else?”, «Σεπτέμβριος 2011 «Γοητευτική Αθήνα», etc.). These titles are brief and telegraphic, due to frame/layout constraints (max 100 characters including logo and date). The rule of thumb that applies here is the use of key-words, and the extensive use of exclamation and question marks. As a mnemonic technique applied in order to lure the reader into downloading the issue and reading it through, English titles are also used, such as subject titles taken from lyrics of famous songs.
- (3) Titles. The titles precede the so-called “teasers”.² Their main characteristics are as follows:

- They present the text’s main theme (core info), or the topics of the newsletter in general.
- They entice the reader (the potential tourist) as attention-grabbing devices.
- They reinforce the message sent by the GNT0 according to the general marketing plan, i.e. to promote Greece as a year-round destination.
- Furthermore, we can observe some differences in the way titles are written triggered by the changes in the layout adopted in December 2011:
 - a. Titles became shorter. This change led to the increase in rhetorical figures, rhetorical questions, and playful language –all employed to create mystery and lure the reader into reading the newsletter articles and visiting the GNT0 website–, and there was a corresponding decrease in melodic punctuation (question marks, exclamation marks, quotation marks and dots). Thus, the reader’s attention is captured by the use of an enigmatic way of presenting the information, a typical characteristic of the language of advertising.

b. In June 2011 numbers were used in titles for the first time (i.e. Top 6 family destinations). Apparently, the idea was to give the reader more condensed focused information and to help potential tourists decide which place to visit in Greece and why.

Here are some examples of the newsletter titles in both languages:

(1a) The islands of Paxoi & Antipaxoi

(1b) Παξοί και Αντίπαξοι

(2a) Rock climbing on Kalymnos island

(2b) Αναρρίχηση στην Κάλυμνο

(3a) Top 6 family destinations: Just for you, kids!

(3b) Κορυφαίοι προορισμοί για οικογενειακές διακοπές

Other characteristics of the newsletter titles are:

a. The preference of elliptical sentences and noun phrases (especially in Greek):

(4a) The Armata re-enactment lights up the sky!

(4b) Εκρηκτική Αρμάτα!

(*Literal Translation: Explosive Armata!*)

(5a) “I will” you said. To be continued on Santorini...

(5b) Γάμος με θέα...την καλντέρα!

(*Literal Translation: Wedding with a view...of a caldera*)

(6a) Stand still...A butterfly might touch you.

(6b) Καλοκαιρινές διακοπές και πεταλούδες. Τέλεια;

(*Literal Translation: Summer holidays with butterflies. Perfect?*)

(7a) The IMF is being celebrated at the carnival of Xanthi.

(7b) Ξανθιώτικο Καρναβάλι: ΔΝΤ και η μεγαλύτερη μάσκα στον κόσμο.

(*Literal Translation: The Xanthi Festival. The IMF and the biggest mask in the world*)

b. The use of questions (sometimes transferred as answers in Greek):

(8a) Do skiers find Vassilitsa the most beautiful ski resort in Greece?

(8b) Για κάποιους σκιέρ η Βασιλίτσα είναι το ομορφότερο χιονοδρομικό στην Ελλάδα.

(*Literal Translation: According to some skiers Vassilitsa is the most beautiful ski resort in Greece.*)

(9a) Hmm...Still in Crete. Let's try something different.

(9b) Είστε έτοιμοι για τη διαδρομή που σας προτείνουμε;

(*Literal Translation: Are you ready for the route we recommend?*)

(10a) Intense ski activity on Mt. Helmos

(10b) Ατελείωτες χιονοδρομικές πίστες, μυθολογία, ιστορία, μυστήριο. Καλάβρυτα;

(*Literal Translation: Endless ski runs, mythology, history, mystery. Kalavrita?*)

c. The use of rhetorical questions. In the following examples this use is limited to each language, meaning that if a rhetorical question is used in Greek it is not transferred to English, and vice versa.

(11a) Colours and Aromas of Spring in the Garden of Music

(11b) Πάσχα στην Κέρκυρα. Τι άλλο να πει κανείς;

(*Literal Translation: Easter on Corfu. What else can you say?*)

(12a) Stand still...A butterfly might touch you.

(12b) Καλοκαιρινές διακοπές και πεταλούδες. Τέλεια;

(*Literal translation: Summer holidays with butterflies. Perfect?*)

- d. Extended use is made of figures of speech (metaphor, personification, etc.). These rhetorical devices are not always translated/transferred into the other language (Greek or English, respectively):³
- (13a) A mastic-scented island with a fascinating history
(13b) Ένα γλυκά «αρωματισμένο» νησί με πλούσια ιστορία
- (14a) On Easter Sunday a gastronomic marathon takes place.
(14b) Μύρισε Πάσχα...ελληνικό!
(*Literal Translation*: Smell the Easter – the Greek one!)
- (15a) Love, Made in Greece
(15b) Όταν ο κινηματογράφος ερωτεύεται την Ελλάδα.
(*Literal Translation*: When the cinema falls in love with Greece)
- (16a) Crete gazes at the Libyan Sea. Do the same!
(16b) Ένα βραχώδες έργο της φύσης αγγίζει τη θάλασσα.
(*Literal Translation*: A rocky work of nature that touches the sea)
- e. Playful language (mostly appearing in English):
- (17a) Cross these bridges when you come to Epirus.
(17b) Αναζητήστε τα πέτρινα γεφύρια της Ηπείρου.
(*Literal Translation*: Look out for the stone bridges in Epirus.)
- f. The use of melodic punctuation: (Usually the same when a pair of titles share the same meaning and they are translated from one language to another, but different when a totally different title is initially written in English or Greek):
- (18a) Revitalise your senses!
(18b) Αναζωογόνησε νου και σώμα!
(*Literal Translation*: Rejuvenate your mind and body)
- (19a) A spiritual celebration...
(19b) Δεκαπενταύγουστος: Το Πάσχα του καλοκαιριού
(*Literal Translation*: August 15th: Easter in summer!)
- (20a) Loving nature while bathing in sunlight!
(20b) Στη Φύση της Ελλάδας με αγάπη...
(*Literal Translation*: To Greece's nature with love...)

(4) Editorials. They were first introduced in January 2011 to add a more personal tone to the newsletter. They represent the collective voice of the web team working at the GNTO, and with a signature at the end of the editorial text the sender of the message displays their own recognisable identity.

Figure 6 The typical form of an editorial

Editorials are usually in the form of a small text (app. two paragraphs in length). Their main lexicogrammatical features are:

- exclusive first-person plural, e.g. *we think/πιστεύουμε*
- second person imperatives (to guide potential tourists; Maci 2007), e.g. *Μην ξεχάσετε/Don't forget, etc.*, because editorials are written by copywriters who represent a national organisation and offer readers compelling reasons to visit Greece.
- Finally, the message communicated is often linked with the general social and political climate in Greece, often using allusion –especially in the editorials written in Greek addressing the Greek readership:

(21a) [...]Λοιπόν, πιστεύουμε ότι ήρθε η ώρα να πάρουμε όλοι μια πρώτη γεύση από το θρυλικό ελληνικό καλοκαίρι, αυτό που ζούμε ως Έλληνες και αγαπάμε. Αυτό που, τελικά, μετά από έναν βαρύ χειμώνα θα χρωματίσει τη ζωή μας με: γλυκιά ξενοιασιά, άπλετο φως, παιχνίδια στη θάλασσα, σημάδια από τον ήλιο, περιπέτεια και ανεκτίμητες παιδικές (και όχι μόνο) αναμνήσεις [...]. (May 2011 issue)

(21b) So, we think it's about time for you to get your first taste of the legendary Greek summer. The summer we here in Greece know and love. (In Greek the phrase “The summer which after a *hard winter* will paint our life with [...].) (May 2011 issue)

However, depending on the topics (when they are more romantic, or when major celebration such as Easter is being presented), the typical editorial form is replaced by: (a) a poem (Figure 7a; April 2011 issue), or (b) an unconventional type of writing (Figure 7b; March 2011 issue), such as melodic punctuation, capital letters, lack of punctuation, full stops that break up phrases and isolate words. In this way “[...] writing is a form of image-making too”: Goddard 1998).

Figures 7a & 7b Other forms of editorial

(5) Leads. Leads are based on a twofold structure with which readers ascertain facts from the text and are then encouraged to try things out themselves. Accordingly, leads attempt to persuade or inspire readers to read the main article (hypertext), and provoke a reader's curiosity to continue reading the visitgreece website, creating another viewing opportunity. They also support the title (headline) and save readers' time, giving them the most important information in a clear, concise and interesting manner. In addition, leads establish the voice and direction of an article and the point of the story.

In the visitgreece newsletter they are constricted by the layout/frame (max 450 characters), and they form part of a module that consists of: a title, a photo (image), a text, and colour (the blue frame around them) (multimodality).⁴ The messages conveyed through leads are addressee-oriented, since the active voice, the first and second-person plural pronouns and the imperative and subjunctive mood are mostly employed. Thus, a conversational style is adopted (conversationalisation) that helps messages become more intermediated, asynchronous and interactive.

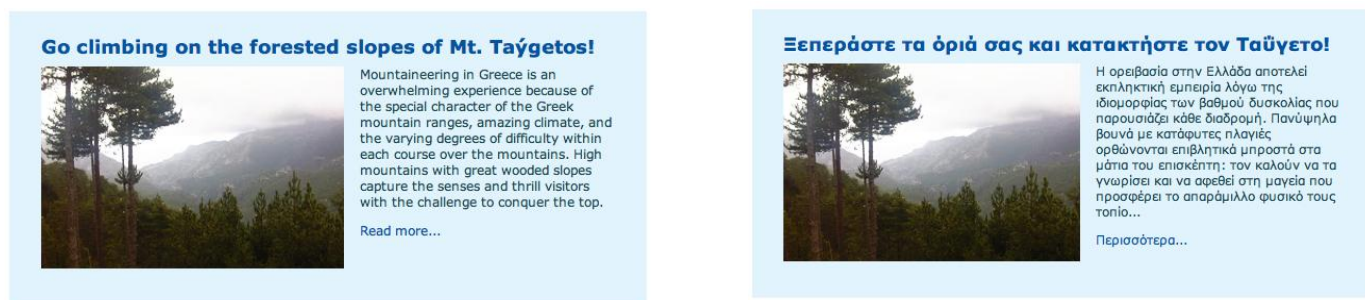

Figure 8 Leads

In this type of text the following rhetorical tropes and lexico-grammatical features are also used:

- Generics (*οι άνθρωποι, Ολόκληρος ο κόσμος απολαμβάνει τα δώρα της Αρχαίας Ελληνικής Αρχιτεκτονικής*)
- Common evaluative adjectives (*marvellous, glorious, μοναδική, μαγευτική* etc.)
- Lexical collocations (*μαγευτικές παραλίες, αρχέγονη φυσικότητα, ιδανικό σκηνικό, αυθεντική επαφή, rare natural wealth, unique wildlife habitats, etc.*)
- Mental state attribution (*the whole world enjoys the gifts of Ancient Greek Architecture, etc.*)
- Hyperbole (*enormous variety..., Η ιππασία συνδυάζει μοναδικά τη δυνατή περιπέτεια, Horse backriding offers a unique adventure, etc.*), to enhance the persuasive power of the message (Ip 2008)
- Personification (*...βουνά...τον καλούν να..., the mountains invite the visitor to...*)
- Rhetorics of Writing: words written with capital first letters (*the Greek Ideal of Beauty, το ιδεώδες του αρχαίου ελληνικού Κάλλους, etc.*)

- (6) The “special feature” section. Since January 2011, licensed tourist guides have written a text every month in English and Greek which is added to the monthly newsletter issues. These texts form part of the visitgreece website content and are actually hypertexts connected with the newsletter. In this way, the “special feature” section is a small text used as an introduction to the topics presented by the tourist guides. Its main characteristics are:

- present tense (the tour is being conducted as we speak);
- future tense (e.g. *together we will discover, they will give all the necessary information, etc.*)
- suggestions: mostly for social advertising rather than commercial (*Let's follow them...*)⁵
- inclusive “we” and “you”;
- synonymous phrases, expressing in different ways the tours that the tourist guides are taking us on: *“they tell their own story...”*; *“they will give all the necessary information...”*; *«οι ξεναγοί μάς οδηγούν», «καθοδηγούν την περιπλάνησή μας», «μας υποδέχονται»* etc.

Figure 9 The “special feature” section

- (7) The video section. In May 2011 the video section was first introduced. As seen from the figure below, the text is taken from the ID-project YOUNGREECE, where the goal of this campaign is presented. From June onwards the same text has been used in both languages, thus promoting the campaign YOUNGREECE as a tourism marketing initiative implemented by the GNT0.

Figure 10 The video section

- (8) The social media section. The newsletter has become more interactive and followers are rewarded for their tweets, with the best tweet being included in the newsletter.

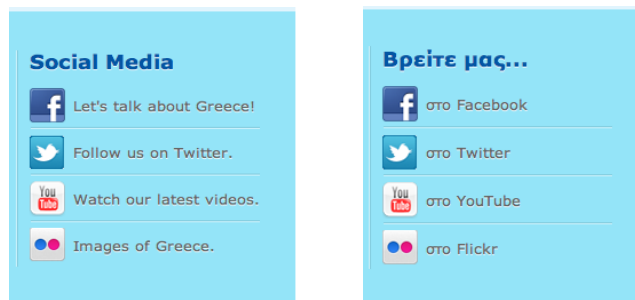

Figure 11 The social media section

- (9) The footer. Formed by standing details which help transform DESIRE into ACTION (cf. Ungerer 2004).

Figure 12 The footer

4. A few words about hyperlinks

Hyperlinks are clear “call to action” messages (*Δείτε το βίντεο, Πήγαινε με εκεί, Read more, Take your pick*, etc.). They are short phrases written under each lead, or any other type of text composed for other newsletter sections (“special feature”, video etc.). Newsletter hyperlinks take the readers on a tour inside the website where they find a multimodal hypertext consisting of text and image, or text, image and video. Inside these hypertexts more links lead the reader to a path made by the copywriter via key information (again use of key words), i.e. general info about a place or a site.⁶

5. Some comments on translation

As stated by Cappelli (2008) “The translated text (TT) must have a function equivalent to that of the source text (ST) and this requires a “cultural filter”, which is a sort of “adaptation” of the translated text to make up for socio-cultural, stylistic and rhetorical differences between the ST and the TT”. Regarding the GNTTO English and Greek newsletter issues, Greek is not always the source language,

since some of the texts are written in parallel in English and Greek (by different copy-writers). Nonetheless, a considerable number of Greek texts are translated into English. Either way, the texts (and the translated versions) fulfil the same function, that is, to promote Greece and persuade readers to visit the country. The “adaptation” process Capelli (op.cit.) mentions can be seen in the attention paid to each language’s basic principles, e.g. lighter constructions in English as well as the stylistic and rhetorical differences found in the use of punctuation and poetic language (cf. section 3). Furthermore:

- “localisation” is a process adopted in English language texts since great care is taken to reflect the target language’s linguistic and cultural preferences;
- Key words, keying and cliché phrases are used in both languages (special attention is paid to the use of English collocations);
- emphatic language (language euphoria: Dann 1996) is common.

In general, the strategies of tourism and promotional discourse are followed in both languages.

6. General conclusions

The Greek National Tourism Organisation as a social actor and a governmental entity has been using the reconstruction of the visitgreece.gr portal and the newsletter in particular to convey values that enhance a certain political message, that is, the attempt to restore Greece’s damaged image, and to promote the country as an attractive tourism destination. Drawing upon pre-existing conventional discourse types in order to create a positive image for Greece the organisation has made use of:

- (a) new technologies: the Internet, smartphones –the so-called “computer-mediated environment”;
- (b) new media: social media: facebook, twitter, Flickr;
- (c) specific discourse strategies within a specific socio-cultural situation, and communicative situation in order to influence readers all round the world and persuade them to become visitors to Greece.

The [visitgreece](http://visitgreece.gr) newsletter comprises all the attributes that are characteristic of a promotional travel genre distributed via the Internet forming eventually a novel hybrid cybergenre, because:

- (1) It is a multimodal semiotic entity:
 - it uses a wide range of multimodal resources (text, video, image) aimed at “encouraging” people from all over the world to visit Greece;
 - its layout is determined by the medium: it is vertically organised to be easily read on the Internet.
- (2) Unlike other genres of tourism discourse (e.g. brochures, guidebooks, etc.):
 - it demonstrates a certain degree of interactivity and intimacy since the addressee signs up to receive it;
 - the mode of address (use of the pronoun systems) which is frequently present in the newsletter texts, minimises the social distance, showing familiarity and equality;
 - present tense verbs foster a sense of involvement.
- (3) In the [visitgreece](http://visitgreece.gr) newsletter texts are written according to the main principles of Promotional/Advertising/Tourism Discourse as they:
 - (a) meet the classic requirements of the AIDA principle: capture Attention, create Interest, foster Desire and inspire Action;
 - (b) contain evaluative language (repetition of positive adjectives);
 - (c) make use of hyperbolic language and images;
 - (d) employ special words and formulae/specific vocabulary;
 - (e) utilise key-words (authentic, discover, adventure, dream, destination, etc.);
 - (f) imperatives and directives are frequently found;
 - (g) prototypical advertising discourse is found: extensive use of NPs.
- (4) The GNTTO newsletter is a novel emergent cybergenre, because:
 - (a) it constitutes a conventionalised web-textual form;
 - (b) it is wholly dependent on the new medium, i.e. the Internet;
 - (c) it incorporates discursive elements of promotion, drawing upon news report discourse, and
 - (d) it offers favourable information encoded into promotional messages according to underlying principles of credibility (news writing) & desire (ads).

¹ The initiative is described as follows: "YOUINGREECE is about real people from different backgrounds, nationalities and lifestyles, who choose to visit Greece travelling from all over the world. People, just like you, who pass on the message that Greece is a country whose authenticity, natural beauty, and warm hospitality are uniquely combined attributes".

² These are the small texts that accompany the photos, which are also defined as "leads" (ibid section 3, paragraph 5).

³ With reference to translation we should pay attention to whether the rhetorical devices are transferred, e.g. the use of metaphor, and not whether the title is translated as such.

⁴ Click rates show to what extent leads attract readers and measure the effectiveness of leads.

The lead paragraph summarises the central action by answering the questions "who", "when", "where", "what", and sometimes "why" (Erjavec: 563).

⁵ Social advertising: It is about applying marketing and advertising principles to promote health and social issues and bringing about positive behavior change.

⁶ Newsletter and hypertexts: the structure is similar to that of a journey. From the general presentation we move to a specific place, to the heart of the information.

ABSTRACT

Τα τεράστια κειμενικά δεδομένα που είναι διαθέσιμα σήμερα σε ηλεκτρονική μορφή απαιτούν εύρωστες τεχνολογίες επεξεργασίας φυσικής γλώσσας (ΕΦΓ). Η αλυσίδα αρθρωμάτων ΕΦΓ που έχει αναπτύξει το Ινστιτούτο Επεξεργασίας του Λόγου είναι μοναδική για την Ελληνική γλώσσα και μπορεί να χρησιμοποιηθεί τόσο για τη μελέτη διαφόρων γλωσσικών φαινομένων για ερευνητικούς σκοπούς όσο και για την αυτόματη ανάλυση κειμενικών συλλογών με στόχο την αποδοτικότερη δεικτοδότηση και χρήση τους. Τα εργαλεία που παρουσιάζονται σε αυτό το άρθρο στηρίζονται σε τεχνικές μηχανικής μάθησης αλλά και σε νομοθετικές προσεγγίσεις. Τα περισσότερα είναι ήδη διαθέσιμα ως διαδικτυακές υπηρεσίες από τη διεύθυνση <http://nlp.ilsp.gr/ws/>.

1. Introduction

The vast amount of electronically available textual data constitutes a wealth of information for both researchers and application developers. On the other hand, the overwhelmingly big datasets of today ask for robust and efficient processing tools. While a variety of relevant processors exist for well-resourced languages like English, it is often difficult to find similar tools for texts in less-spoken languages. In this paper we provide an overview of natural language technologies available from the Institute for Language and Speech Processing. This NLP suite is unique for the Greek language and comprises a series of processing units based on both machine learning algorithms and rule-based approaches. We report on updated versions of tools originally presented in Papageorgiou (2002) and, taking into account latest developments in this field, on new processors that we have implemented, together with the resources we created for their training and evaluation. Our infrastructure can be used by researchers interested in studying linguistic properties of the Greek language. At the same time, it can be employed in application scenarios involving fast processing of large document collections.

The paper is organized as follows. Section 2 discusses detection of paragraph, sentence and token boundaries in input text. Modules presented in Section 3 assign POS tags and lemmas to tokens. Section 4 presents a dependency treebank for training data-driven parsers. A term spotting algorithm is discussed in Section 5. Sections 6 and 7 focus on modules for sentence compression and text summarization. In Section 8, we discuss integration and use of the tools via standards-compliant web services.

2. Paragraph, sentence and token segmentation

At the first stage of our processing architecture, input is channeled to a module that segments text into paragraphs, sentences and tokens. Input is read from locally stored text files or from documents collected from the Internet, stripped of their HTML markup (apart from paragraph tags) and stored as XML files.

When paragraph segmentation is available in the input as paragraph markup, this is taken into account. In the opposite case, a paragraph segmentor detects first whether input text has paragraphs broken across lines. The segmentor counts the relative frequency of non-empty lines that begin with a character that is not a capital letter or any kind of opening quote, dash, or opening bracket. If the relative frequency is less than 0.35, the tool assumes that end of lines constitute paragraphs. Otherwise, it assumes that input text contains line-broken paragraphs and extends paragraph boundaries until a set of constraints, including occurrence of empty or relatively short lines, is satisfied.

Sentence boundaries are detected inside paragraphs. The text of each paragraph is first segmented on obvious sentence-final punctuation marks (e.g. ., !), while a set of rules based on regular expressions takes care of not splitting strings like Internet URLs or currencies (e.g. *http://www.host.gr/quote?id=NBGr.AT*, *sftp://vls@ftp.ilsp.gr*, or *35.000*). Following this simplistic segmentation, a set of post-processing heuristics is used to join wrongly split text segments into sentences. As an example, these heuristics examine whether the sentence previous to the one scanned ends with an abbreviation. For a string to be classified as an abbreviation, the tool consults an abbreviation list containing approximately 2K entries. Alternatively, it checks whether the string matches a relevant regular expression. If the previous sentence ends in a non-breaking abbreviation like *άρθρ.*, *Δρ.* or *δηλ.*, the two sentences are joined into one. In the case of abbreviations that can occur in a sentence-final position like *Σ.τ.Ε.*, *Α.Ε.* or *χλμ.*, the initial sentence split is maintained if the second sentence starts with a capital letter. Similar heuristics are used for correcting splits between initials and last names, or splits in texts with line-broken paragraphs.

The next process is tokenization, i.e. the recognition of word and punctuation boundaries inside the text of each sentence. This again involves an initial split at obvious points in the input text (spaces, punctuation marks, etc.), followed by some postprocessing. The latter includes cases like avoiding the separation of the relative indefinite pronoun *ό,τι*; splitting the 2nd and 3rd personal pronoun combination *σ'το* in two tokens; disambiguating between contracted forms like *'ρθει* and quote-token combinations like *'ερθει* and recognizing one and three tokens, respectively; splitting off the period from the last word of the sentence, but remembering not to do it when the last word is an abbreviation like *Ο.Η.Ε.*; detaching parentheses and hyphens but not in the case of enumerators like *2.1.1)* or of negative numbers like *-12,32*; etc. Each detected token is assigned a token type on the basis of the token itself and, in certain cases, the context of the token. The list of token types with some indicative examples is shown in Table 1.

Token type	Example	Token type	Example
DATE	16/6/43	ENUM (enumerator)	2.1 i. a)
PUNCT (punctuation)	, - · (ano-teleia)	DIG (digit)	1.0009,1% - 3/8 3/4
PTERM (terminal punct.)	;!...	INIT (initial)	T. Χρ. Γερ.
PTERM_P (potentially terminal punct.)	. : ; !	ABBR (abbreviation)	δισ.ΟΓΑ ΣΥ.ΠΙ.ΖΑ
OPUNCT (opening punct.)	« " ([{	NBABBR (non-breaking abbr.)	π.χ. αναφ.
CPUNCT (closing punctuation)	» ")] }	TOK (default)	Default type for all other tokens

Table 1 Token types

Sentences are also assigned a type attribute based on their capitalization. The list of values for sentence types includes `uppercase` for sentences typed in capital letters and `titlecase` for sentences where the first letter of every token is capitalized. An optional process involves normalization of `uppercase` sentences or sentences with regular capitalization, when no diacritics have been used by the author of the text. In this step, diacritics are restored to ease processing of other downstream processors like part of speech taggers and parsers. Diacritic restoration is performed as in Scannell (2011) by querying a lexicon of frequent words and, in the case of ambiguity (*δίκη/δική*), a table of bigram probabilities (e.g. *δίκη| - |πολιτική*) learned from large crawled corpora of Greek.

3. Part of speech tagging and lemmatization

After tokenization, we add morphosyntactic annotations to each token using a part of speech tagger called FBT. FBT is an adaptation of the Brill tagger (Brill, 1992) trained on a manually annotated corpus of Greek texts amounting to 455K tokens. During manual and automatic annotation, we use a tagset of 584 combinations of basic POS tags (Table 2) and morphosyntactic features, which capture the rich morphology of the Greek language¹. As an example, the full tag *AjBaMaSgNm* for a word like *παράωδης* denotes an adjective of basic degree, masculine gender, singular number and nominative case.

POS	Description	POS	Description
Ad	Adverb	PnIr	Interrogative pronoun
Aj	Adjective	PnPe	Personal pronoun
AsPpPa	Preposition + Article combination	PnPo	Possessive pronoun
AsPpSp	Preposition	PnRe	Relative pronoun
AtDf	Definite article	PnRi	Relative indefinite pronoun
AtId	Indefinite article	PtFu	Future particle
CjCo	Coordinating conjunction	PtNg	Negative particle
CjSb	Subordinating conjunction	PtOt	Other particle
PnDm	Demonstrative pronoun	PtSj	Subjunctive particle

Table 2 Common part of speech tags

For the construction of the corpus, linguists had to correct automatically assigned tags from an initial version of the tagger. We used interfaces that allow annotators to select between (features of) tags for ambiguous tokens. For example, in Figure 1, a user selects the *Nm* (nominative) value for the case feature to correct a wrongly assigned *Ac* (cussative) for the noun *στρατόπεδο*.

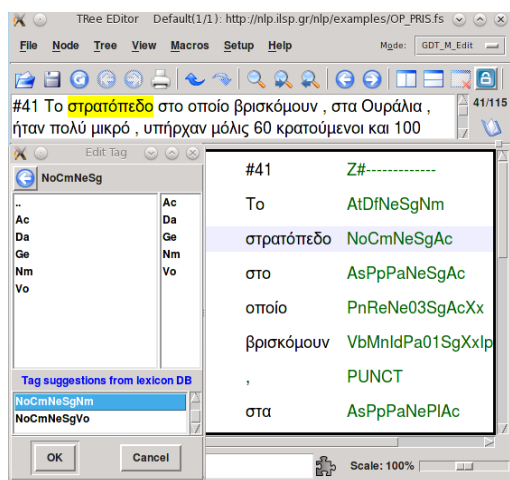

Figure 1 User interface for annotation of POS tags

Input	του μνημονιακού/AjBaNeSgGe χειμώνα/NoCmMaSgGe
Rule	AjBaNeSgGe ->AjBaMaSgGe NEXTTAG NoCmMaSgGe
Output	του μνημονιακού/AjBaMaSgGe χειμώνα/NoCmMaSgGe
Input	απατείται διαρκής/AjBaFeSgNm επαγρύπνηση/NoCmFeSgAc
Rule	NoCmFeSgAc ->NoCmFeSgNm PREVTAG AjBaFeSgNm
Output	απατείται διαρκής/AjBaFeSgNm επαγρύπνηση/NoCmFeSgNm

Table 3 Context rules correcting gender and case

During automatic processing, the tagger assigns to each token the most frequent tag in a lexicon compiled from the training corpus and augmented with entries from ILSP's Morphological Lexicon². A lexicon of suffixes guides initial tagging of unknown words: for example, an entry like *νιλακού-* *AjBaNeSgGe* would assign this specific tag to a word like *μνημονιακού*. After that, a set of about 800 contextual rules is applied to correct initial tags. The rules were automatically learned from the training corpus as detailed in Papageorgiou et al. (2000). When a token exists in the lexicon, rules are allowed

¹ See http://nlp.ilsp.gr/nlp/tagset_examples/tagset_en/ for a full description of the tagset, including all morphosyntactic features and indicative examples.

² <http://www.ilsp.gr/en/services-products/langresources/item/32-ilektronikomorfologiko>

to change its tag only if the resulting tag exists in the token's entry in the lexicon. As an example of rule application, the first rule in Table 3 would assign a masculine value for the gender feature of *μνημονιακού* in a context like *μνημονιακού χειμώνα*. FBT's accuracy has been tested against a 90K partition of the manually annotated corpus not used in training. The tagger's accuracy reaches 97.49% when only basic POS is considered. When all features (including, for example, gender and case for nouns, and aspect and tense for verbs) are taken into account, the tagger's accuracy is 92.54%.

Following POS tagging, a lexicon-based lemmatizer retrieves lemmas from the Morphological Lexicon. This resource contains 66K lemmas, which in their expanded form extend the lexicon to approximately 2M different entries. When a token under examination is connected in the lexicon with two or more lemmas, the lemmatizer uses information from the POS tags assigned to disambiguate. For example, the token *ενοχλήσεις* will be assigned the lemma *ενοχλώ*, if tagged as a verb, and the lemma *ενόχληση*, if tagged as a noun.

4. Dependency parsing

One of the most prominent current paradigms in automatic syntactic analysis is dependency parsing. Dependency parsers create tree representations for each input sentence, where each word depends on a head word and is assigned a label depicting its relation to the head word. Treebanks with manually created annotations are used to train and evaluate data-driven dependency parsers. We have trained open source parsers on the Greek Dependency Treebank, a resource that comprises data annotated at several linguistic levels (Prokopidis et al., 2005). As of 2011, GDT contained 118+K tokens in 4948 sentences, while more annotated texts are being added³. Lemmas and POS tags for all tokens are manually validated. The texts include transcripts of European parliamentary sessions, articles from the Greek Wikipedia and web documents pertaining the politics, health, and travel domains.

Dep. Rel	Description	Dep. Rel.	Description
Pred	Main sentence predicate	Coord	A node governing coordination
Subj	Subject	Apos	A node governing apposition
Obj	Direct object	* Co	A node governed by a Coord
IObj	Indirect object	* Ap	A node governed by an Apos
Adv	Adverbial dependent	AuxC	Subord. conjunction node
Atr	Attribute	AuxP	Prepositional node
ExD	A node whose parent node is not present in the sentence (ellipsis)	AuxV	Particles or auxiliary verbs attached to a verb

Table 4 Common dependency relations in the Greek Dependency Treebank

The scheme used during manual annotation includes 25 main relations (Table 4) and is based on an adaptation of the guidelines for the Prague Dependency Treebank (Böhmová et al. 2003). The guidelines include indicative examples of several syntactic phenomena. For example, coordination structures (Figure 2) are headed by a conjunction assigned the label *Coord*, while each node headed by the conjunction is annotated with a label like *Obj_Co*. These labels denote both the node's function in the sentence and the fact that it participates in a coordination structure.

Figure 2 Representation of coordination structures

The scheme allows for simple and intuitive descriptions of structures common in languages which, like Greek, exhibit a flexible word order. Since dependency relations are directly encoded, without the

³ Updated information on the GDT can be found at <http://gdt.ilsp.gr/>.

presupposition of any default constituent structure from which all others are derived, representation for the main relations in a sentence is straightforward. In an OVS example like *την έγκρισή τους έδωσαν οι υπουργοί*, the verb *έδωσαν* heads the sentence as the main predicate, while two words, *έγκριση* and *υπουργοί*, are annotated as object and subject dependents of the predicate respectively.

Non-projective structures are also allowed in the scheme. As an example, subjects or objects extracted from an embedded clause can be linked to their head without the use of co-indexation with a trace. This is illustrated in the non-projective tree of Figure 3, where the relative pronoun *οποία* directly depends as a subject to its head *έλειπαν*, thus crossing the link of the verb heading the relative structure to the antecedent.

Figure 3 Non-projective relation

In n-fold experiments with the MaltParser system for dependency parsing (Nivre, 2007), we have trained models on the GDT that showed an overall labeled attachment score (i.e. the proportion of tokens attached to the correct head and assigned the correct dependency relation) of 74.83% and an overall unlabeled attachment score of 81.04%. Precision and recall for the subject relation reached 83.49% and 89.46% respectively.

5. Term extraction

We can view terms as linguistic realizations of domain specific concepts, usually lexicalized in the form of noun phrases. For terminology recognition we have implemented a hybrid methodology: we initially construct a candidate term set using a term grammar and then filter this set through statistical techniques. The module operates on input with lemmas and part-of-speech tags assigned to each word. First, the following term pattern grammar recognizes single and multi-word (up to 4-word) candidate terms:

$$((\text{Adj}|\text{Noun}) * (\text{Prep}|\text{Det})?) (\text{Adj}|\text{Noun}) * \text{Noun}$$

Then, a statistical filter following the *tf-idf* paradigm is applied to the list of grammar-extracted terms in order to rank them according to statistical evidence. The reference corpus used in the *idf* calculation is the Hellenic National Corpus (HNC, <http://hnc.ilsp.gr>), a 47M words tagged and lemmatized corpus covering a wide range of topics including, among others, news, literature, science and business. The following formula calculates the confidence score for a term:

$$\text{Score}(\text{candidate}) = \text{tf} \cdot \log(\text{idf})$$

In the case of 2-word terms we use contingency table statistics (Daille, 1995). For a given pair $w_i + w_j$ (as, for example, in the case of noun + noun), the contingency table is defined as in the following table:

	w_i	$w_j, j \neq i$
w_i	a	b
$w_i, i \neq i'$	c	d

Table 5 Contingency table for 2-word terms

where a stands for the frequency of pairs involving both w_i and w_j (number of occurrences of a pair); b stands for the frequency of pairs involving w_i and w_j (number of occurrences of pairs where a given word appears as the first element of the pair); c stands for the frequency of pairs involving w_i and w_j (number of occurrences of pairs where a given word appears as the second element of the pair); and d stands for the frequency of pairs involving w_i and w_j and has a constant value calculated from the HNC

(total number of occurrences of all the pairs in the reference corpus). The score formula is based on log-likelihood:

$$\begin{aligned} \text{Score}(2 - \text{word}) = & a \cdot \log(a) + b \cdot \log(b) + c \cdot \log(c) + d \cdot \log(d) \\ & - (a + b) \cdot \log(a + b) - (a + c) \cdot \log(a + c) \\ & - (b + d) \cdot \log(b + d) - (c + d) \cdot \log(c + d) \\ & + (a + b + c + d) \cdot \log(a + b + c + d) \end{aligned}$$

A couple of factors were taken into consideration in order to smooth the confidence scores across candidate terms with (1) the same number of words and (2) with different number of words. Regarding the former factor, the top-scoring term of each set of terms with the same number of words is assigned a score of 1 (the maximum) and all the others are analogically calibrated from 0 to 1. Regarding the latter factor, in order to account for the fact that *idf* statistics are getting sparser as the number of words increases, we weight the score of a candidate term with the number of words it maintains, in a logarithmic fashion:

$$\text{Score}(n - \text{word term}) = \text{OriginalScore} \cdot (1 + \log(n))$$

Figure 4 displays an example of terms extracted from the sentence: *Σε κινητοποίηση κατεβαίνουν την Τετάρτη και την Πέμπτη οι εργαζόμενοι της Wind και της Vodafone για τις ελαστικές σχέσεις εργασίας (ακόμα και ενοικίαση ή πώληση εργαζομένων!!) αλλά και για τις παράνομες απολύσεις.*

```
<Term conf="0.784" end="#w2" start="#w2" text="κινητοποίηση"/>
<Term conf="0.915" end="#w10" start="#w10" text="εργαζόμενοι"/>
<Term conf="1" end="#w20" start="#w18" text="ελαστικές σχέσεις εργασίας"/>
<Term conf="0.596" end="#w24" start="#w24" text="ενοικίαση"/>
<Term conf="1" end="#w27" start="#w26" text="πώληση εργαζομένων"/>
<Term conf="1" end="#w36" t="#w35" text="παράνομες απολύσεις"/>
```

Figure 4 Example output from the term extractor

6. Sentence compression

Sentence compression is used as a building block in, among others, text simplification and automatic summarization applications. Our sentence compression tool (Prokopidis et al., 2008) processes syntactically analyzed input by a) replacing words with paraphrases shorter in length and b) deleting elements carrying relatively small semantic information.

We used a thesaurus of synonyms and antonyms (Ιορδανίδου, 2005) to manually construct an initial seed of paraphrase lemmas. Paraphrases that were too domain- or register-specific were filtered-out. We then evaluated the seed against the HNC, checking for paraphrase interchangeability and applicability in different linguistic contexts. When all morphological variants of each lemma were automatically generated, we came up with a table of 9860 paraphrase entries consisting of types and morphological features shared by types (Figure 5). Since input is expected to be automatically annotated for the same features, this information guides the paraphrase module in making correct substitutions for homographic source types that may correspond to more than one target types. Thus, if input text contains the noun *θιασώτες*, the module will choose between *οπαδοί* and *οπαδούς* based on the case feature automatically assigned to the source noun.

```
<Paraphrase source="θιασώτες" stag="NoCmMaPlAc" target="οπαδούς" />
<Paraphrase source="θιασώτες" stag="NoCmMaPlNm" target="οπαδοί" />
<Paraphrase source="αγαθοεργίες" stag="NoCmFePlAc" target="ευεργεσίες"/>
```

Figure 5 Paraphrases sharing the same morphological features

A set of deletion rules operates on the output of the paraphrase module. Each deletion rules traverses the nodes of the dependency tree, checking whether specific morphosyntactic constraints apply for the node currently examined. When the constraints match, the node and the subtree that is headed by this node are marked as deletables. Constraints may focus on the node's (or children or

parent nodes') dependency relations, their POS tag, etc. The most frequent actions involve deletions of adjectives (*delAdjs*), adverbs (*delAdvs*, Figure 6) and preposition-headed adverbials (*delPPs*). As an example, *delAdjs* selects as deletion candidates adjectives which a) are not the heads of other nodes (e.g. *ο καλύτερος όλων*) and b) are not headed by a copula verb (e.g. *είναι μόνος*). Subtrees marked to be deleted are ranked according to their *relevance*, which is estimated as in Daelemans et al. (2004) on the basis of the log-likelihood of the frequencies of the subtree words, as these frequencies were observed in a 70M words Greek corpus. Using this information, the deletion of less significant subtrees, which is expected not to seriously affect sentence meaning, precedes elimination of more important subtrees.

Orig: Τις τελευταίες δεκαετίες της τις πέρασε στο Παρίσι, όπου σκόρπισε αφειδώς τα χρήματά της σε αγαθοεργίες.
 Paraphrase 7_1: **αγαθοεργίες -> ευεργεσίες**
 Alt: Τις τελευταίες δεκαετίες της τις πέρασε στο Παρίσι, όπου σκόρπισε αφειδώς τα χρήματά της σε ευεργεσίες.
 Deletion 7_2: (relevance =13.38): **αφειδώς**
 Alt: Τις τελευταίες δεκαετίες της τις πέρασε στο Παρίσι, όπου σκόρπισε τα χρήματά της σε ευεργεσίες.

Figure 6 Reducing sentence length via paraphrase application and subtree deletion

7. Text summarization

Recent work on text summarization has mainly focused on producing extracts rather than abstracts, reflecting the difficulty in tackling complex NLP problems such as anaphora, polysemy, world knowledge, etc. Our summarizer provides extract-based, single document summaries. For each sentence a score, indicative of its salience, is calculated as a weighted sum of several summary-worthy features. The summarization process requires an input with terms and named entities recognized. Currently used features for each sentence include *sentence location*: sentences closer to the beginning of a document are favored; *sentence length*: sentences shorter than n (currently 5) content words are discarded; and *term and named entity occurrence*: inclusion and weight of terms and named entities in a sentence increases the sentence's importance. The scoring formula for all sentences with $length \geq n$ is the following:

$$Score(s) = w_L \log \frac{|D| - Sp + 1}{|D|} + \frac{w_T S_T + w_N S_N}{length(s)}$$

where $|D|$ is the total number of sentences in the document, S_p is the position of the sentence ($1 \dots |D|$), S_T is the sum of confidence scores for each term in the sentence, S_N is the sum of confidence scores for each named entity in the sentence and $length(s)$ is the number of content words in the sentence. The respective feature weights are $\{w_L, w_T, w_N\} = \{1, 4, 4\}$.

The final extract is built from top-scoring sentences selected in their original order in the text. The number of extracted sentences is determined by a compression factor currently set to 10% of the original text. The following figure displays a document with the top-selected extract sentence highlighted.

Ψήφο υπέρ μιας Ευρώπης που θα «μετρά» ως παγκόσμια δύναμη ζητά ο Σιράκ. Ο Σιράκ απέκλεισε το ενδεχόμενο να παραιτηθεί, εάν τελικά οι Γάλλοι καταψηφίσουν το Ευρωσύνταγμα. Το «όχι» στο δημοψήφισμα για το Ευρωσύνταγμα θα καθυστερήσει την ευρωπαϊκή ολοκλήρωση, προειδοποίησε τους Γάλλους πολίτες ο Ζακ Σιράκ, εγκαινιάζοντας δυναμικά την εκστρατεία υπέρ του «ναι» με τηλεοπτική του εμφάνιση. Ο Σιράκ κάλεσε τους συμπατριώτες του να ψηφίσουν «ναι» στο κρίσιμο δημοψήφισμα της 29ης Μαΐου, προκειμένου να συμβάλουν στην οικοδόμηση «μιας Ευρώπης, που θα 'μετρά' ως δύναμη στον κόσμο του αύριο». Ταυτόχρονα, απέκλεισε το ενδεχόμενο παραίτησής του, εάν τελικά ψηφίσουν «όχι» στο Ευρωσύνταγμα.

Figure 7 Top-selected sentence for an extract-based summary

8. Integrating and accessing the tools

Integrating the tools mentioned above into a robust and efficient pipeline capable of analyzing the enormous amounts of texts available online today is not a trivial task. To accomplish this goal, we have wrapped all tools as UIMA (<http://uima.apache.org/>) modules. UIMA is an open source framework for developing analyzers of unstructured data. The framework caters for separation of algorithmic design from input and output requirements and allows NLP engineers to predefine the annotation type system to use. The framework also uses the stand-off annotation practice, where automatic and manual annotations compatible to the type system are separated from primary data.

Our team has been actively involved in national and European projects aiming at automating the stages involved in the acquisition, production, updating and maintenance of language resources and tools. Given the large number of linguistic services and tools already developed by various organizations throughout Europe, the need for building interoperable infrastructures surpassing different underlying technologies becomes apparent. To this end, we have already made available most of the tools described above as web services that can be accessed and tested by linguists or other interested end-users from <http://nlp.ilsp.gr/ws/>. Since these services are standards-compliant, they can be combined with services provided by other teams and organizations in larger processing workflows.

9. Conclusions and future work

We presented a suite of robust processing tools for the analysis of Greek texts that can be used in research and application settings. The tools are developed and evaluated on the basis of several manually annotated resources. We plan to augment this battery of language resources and tools in the hope that this effort will provide valuable support to both theoretical linguists and language engineers. Our current research focuses on the development of tools for coreference resolution and spatiotemporal anchoring of events.

F1 COARTICULATION PHENOMENA IN THE PRODUCTIONS OF GREEK SPEAKERS WITH HEARING IMPAIRMENT

Anna Sfakianaki
Aristotle University
of Thessaloniki, Greece
asfakian@enl.auth.gr

ABSTRACT

Τα φαινόμενα της συνάρθρωσης στην ομιλία των ατόμων με βαρηκοΐα/κώφωση παρουσιάζουν μεγάλο ενδιαφέρον. Ενώ το θέμα αυτό διερευνάται τα τελευταία χρόνια στην αγγλική γλώσσα, δεν υπάρχουν αντίστοιχες έρευνες στα ελληνικά. Η παρούσα εργασία εξετάζει τη θέση και τη διασπορά των τριών ακραίων φηνηέντων, καθώς και τη συναρθρωτική επιρροή από σύμφωνο σε φωνήεν και από φωνήεν σε φωνήεν, σε δισύλλαβες παραγωγές 14 Ελλήνων και Ελληνίδων, 9 με κώφωση (>91 dB HL), και 5 με φυσιολογική ακοή. Η συνάρθρωση μελετάται επί του πρώτου διαμορφωτή, ο οποίος έχει εξεταστεί πολύ λιγότερο από τον δεύτερο διαμορφωτή, παρ'ότι δίνει σημαντικές πληροφορίες για το ύψος της γλώσσας και τη θέση της κάτω γνάθου.

Λέξεις κλειδιά: βαρηκοΐα/κώφωση, ελληνικά, συνάρθρωση, ακουστική ανάλυση, πρώτος διαμορφωτής

1. Introduction

Speakers with prelingual hearing impairment (HI) face serious perceptual constraints. They have acquired speech without the assistance of auditory feedback which has an essential role in the development and continual tuning of the speech production mechanism (Lane et al., 2007). As a consequence, they demonstrate a variety of deficits in their speech, including vocalic and consonantal errors as well as differential coarticulatory patterns and deviant temporal and prosodic characteristics. They tend to produce less differentiated vowels, restricted in formant range, resulting in a reduced vowel space and longer segmental durations (Monsen, 1976a; Whitehead & Jones, 1976; McGarr & Osberger, 1982; Rubin, 1985; Robb & Pang-Ching, 1992; Okalidou, 1996; Ryalls et al., 2003; Nicolaidis & Sfakianaki, 2007; Ozbič & Kogovšek, 2010). Concerning consonantal production, obstruents formed in the middle of the mouth have been found more problematic than more anterior or posterior segments (Nober, 1967; Smith, 1975; Gold, 1978; Barzaghi & Madureira, 2005). The sibilants are among the most problematic articulations for speakers with HI (Markides, 1970; McGarr et al., 2004). EPG patterns of the fricative [s] and the palatals [c] and [X] were found more deviant than that of other consonants produced by Greek speakers with HI (Nicolaidis, 2004).

Many models and theories have been developed to account for the phenomenon of coarticulation in normal hearing (NH) speech. Within the theoretical framework of coproduction, Recasens, Pallarès, & Fontdevila (1997) proposed the Degree of Articulatory Constraint (DAC) Model of Coarticulation. Drawing from the notion of coarticulatory resistance (Öhman, 1966; Bladon & Al-Bamerni, 1976), the DAC model assigns different DAC values to vowels and consonants depending on the articulatory demands for their production. The basic premise of the model concerns the tongue dorsum; the higher the involvement of the tongue dorsum in the constriction formation, the more constrained the phoneme (Recasens, 1985). Constrained phonemes display a high degree of coarticulatory resistance and aggression towards adjacent phonemes. Thus, a highly constrained consonant is expected to exhibit significant consonant-to-vowel (C-to-V) effects, while inhibiting vowel-to-consonant (V-to-C) and vowel-to-vowel (V-to-V) effects.

Regarding HI speech, smaller coarticulatory effects and less consistent coarticulatory patterns than normal have been reported by many researchers (Monsen, 1976b; Rothman, 1976; Baum & Waldstein, 1991; Waldstein & Baum, 1991; Ryalls et al., 1993; Barzaghi & Madureira, 2005). Smaller V-to-C effects compared with other consonants have been displayed for the Greek alveolars [t] and [s]; they

are realized with considerable contact at the palatal region, as shown in an EPG study of Greek HI speech (Nicolaidis, 2007). Reduced V-to-V coarticulation across the bilabial [b] and increased V-to-V coarticulation across the alveolar [d] has been located acoustically along the F2 dimension for American deaf speakers (Okalidou & Harris, 1999). Reduced V-to-C coarticulation for the bilabial [b] and increased coarticulation for the alveolar [d] and the palatal [j] has been observed in F2 locus equations of American HI speech, although patterns were variable among speakers (McCaffrey Morrison, 2008).

To the best of our knowledge, C-to-V and V-to-V coarticulation in HI speech has not been studied systematically along the F1 dimension. Emphasis has been rendered on the F2 axis which mirrors front-back tongue movement. However, F1 coarticulation data can also prove informative as it relates to the degree of tongue and jaw height variation. The vertical dimension has generally been found less problematic, as it is both visually and auditorily more accessible to speakers with HI (Monsen, 1976b). Hence, the main aim of the present study is to examine selected acoustic characteristics of the three point vowels in /pVpV/ disyllables and coarticulation effects along the F1 dimension in /pV₁CV₂/ disyllables with consonants [p, t, s] and vowels [i, a, u] produced by Greek speakers with HI as compared to speakers with NH. In particular we will look at the following characteristics in HI vs. NH speech:

- Position in the acoustic space of point vowels [i, a, u] uttered in bilabial context.
- Anticipatory and carryover C-to-V effects at the temporal midpoint of vowels [i, a, u] along the F1 axis induced by the alveolar stop [t] and the alveolar fricative [s].
- F1 V-to-V effects at V₁ offset (anticipatory) and V₂ onset (carryover) across consonants [p, t, s].

2. Method

Fourteen native speakers of Greek took part in the experiment. The control (NH) group was composed of 5 adults, 2 male and 3 female, without previously reported hearing problems. They were aged 18-21 and were undergraduate students at the Aristotle University of Thessaloniki. The experimental group consisted of 9 adults with HI, 5 male and 4 female, 20-35 years old. The speakers with HI were selected so as to form a group as homogeneous as possible. Their hearing loss was of prelinguistic onset, sensorineural, bilateral, stable and profound, ranging from 91 to 105 dB HL (at 500, 1000 and 2000 Hz). They had been fitted with hearing aid(s) before the age of 4 and made continuous use of them. Most participants had been in speech therapy since the age of 4-8 for 7-12 years at least twice a week. They primarily used oral communication and had a mainstream educational background. Most of them were university students. Their speech intelligibility level ranged from 73% to 98%, as judged by 54 naïve listeners.

The corpus comprised 54 disyllables of the type /pV₁CV₂/ with vowels [i, a, u] and consonants [p, t, s] embedded in the phrase “*leØe _____ pali*” (Say __ again). Half the disyllables were stressed on the first and half on the second syllable, and each item was repeated 10 times. The 540 sentences were randomised and read from a list at a comfortable speaking rate. The speakers with HI were recorded in a soundproof room at the Association of Parents and Guardians of Deaf and Hard of Hearing Children of Central Macedonia, while the speakers with NH were recorded at the Phonetics Laboratory of the School of English, Aristotle University of Thessaloniki. A SHURE unidirectional dynamic microphone, Model BG3.1, attached to a YAMAHA external hard disk recording studio was used for the data acquisition. The data was sampled at 22,050 Hz.

The PRAAT program (Boersma & Weenink, 2011) was used for acoustic analysis. A script was written to provide automatic F1 and F2 frequency LPC measurements for each speaker, utilising a 15 ms Gaussian window at V₁ offset and V₂ onset for V-to-V effects, and a 25 ms Gaussian window at V₁ and V₂ temporal midpoint for vowel acoustic characteristics and C-to-V effects. The automatic measurements were also checked manually; errors were located and corrected. Formant measurements for the unstressed high back vowel [u] were in certain cases excluded due to low energy or extreme shortening/deletion of this vowel.

C-to-V coarticulatory effects were measured at the midpoint of V₁ (anticipatory) and V₂ (carryover) in the symmetrical disyllables /piCi/, /paCa/ and /puCu/. Consonantal effects induced by the two alveolars, [t] and [s], were analysed taking the bilabial context as a base for comparison, e.g., for /t-to-/a/ anticipatory effects, the F1 of the first [a] in /papa/ and the F1 of the first [a] in /pata/ were compared. V-to-V coarticulatory effects were measured at V₁ offset (anticipatory) and V₂ onset (carryover) using a symmetrical disyllable as a base, e.g., for /i-to-/a/ carryover effects over /t/, the F1 of the second [a] in disyllables /pata-/pita/ is measured. The symmetrical disyllable defines the “fixed

vowel” context, which, in this case is the “fixed [a]” context (Recasens & Pallarés, 2000). Univariate analyses of variance were run for variables F1 and F2 in SPSS (v. 17) and Tukey pairwise post-hoc tests were performed in Minitab (v. 15) so as to locate the contexts in which coarticulatory effects are statistically significant for each group.

3. Results

3.1 Vowel space

F1 and F2 formant frequency measurements at the temporal midpoint of the three point vowels [i, a, u] were made in symmetrical /pVpV/ disyllables. The interaction hearing*vowel was found statistically significant (F1: $F(2, 15036)=61.897$, $p<.0001$, F2: $F(2, 15045)=2650.994$, $p<.0001$). Post-hoc tests revealed that the F2 of [i] was significantly lower for the HI group and that of [u] was significantly higher compared with those of the corresponding NH high vowels. Thus, the high front vowel [i] seems to be more posteriorly articulated and the high back rounded vowel [u] significantly fronted in HI speech. In addition, the mean F1 value of the HI point vowels was overall relatively lower than that of the corresponding NH vowels, suggesting a somewhat less open vowel articulation by the speakers with HI. However, only HI [u] was found significantly higher than its NH counterpart (see Figure 1). These differences lead to a reduction of 36% on average in the vowel space as defined by HI point vowels compared with that of NH point vowels.

Figure 1 NH (solid line) and HI (dashed line) vowel space. The symbol [*] denotes statistically significant difference ($p<.05$) between the NH and HI group in both F1 and F2 for [u] and in F2 for [i].

3.2 Consonant-to-Vowel Coarticulation

F1 formant frequency was measured at V_1 and V_2 midpoint in the consonantal context of [p, t, s] in /pV₁CV₂/ disyllables. The F1 difference between the bilabial and the alveolar contexts ($\Delta F1$) for the NH and HI group is shown in Figure 2. The hearing, vowel and consonant factors were all found statistically significant as well as their interactions (hearing: $F(1, 15036)=463.755$, $p<.0001$, vowel: $F(2, 15036)=67791.626$, $p<.0001$, consonant: $F(2, 15036)=96.190$, $p<.0001$). Both groups present more coarticulation on the low vowel [a] than on the two high vowels [i] and [u], with effects reaching statistical significance only in HI /pasa/ vs. /papa/ disyllables in both directions. Hence F1 coarticulatory effects are overall more prominent for the HI group. It is therefore noteworthy that, in HI

[F1 COARTICULATION PHENOMENA IN THE PRODUCTIONS OF
GREEK SPEAKERS WITH HEARING IMPAIRMENT]

coarticulation, the fricative causes F1 lowering in all three vocalic contexts which is especially pronounced in the fixed [a] context (see bars with red stripes in Figure 2).

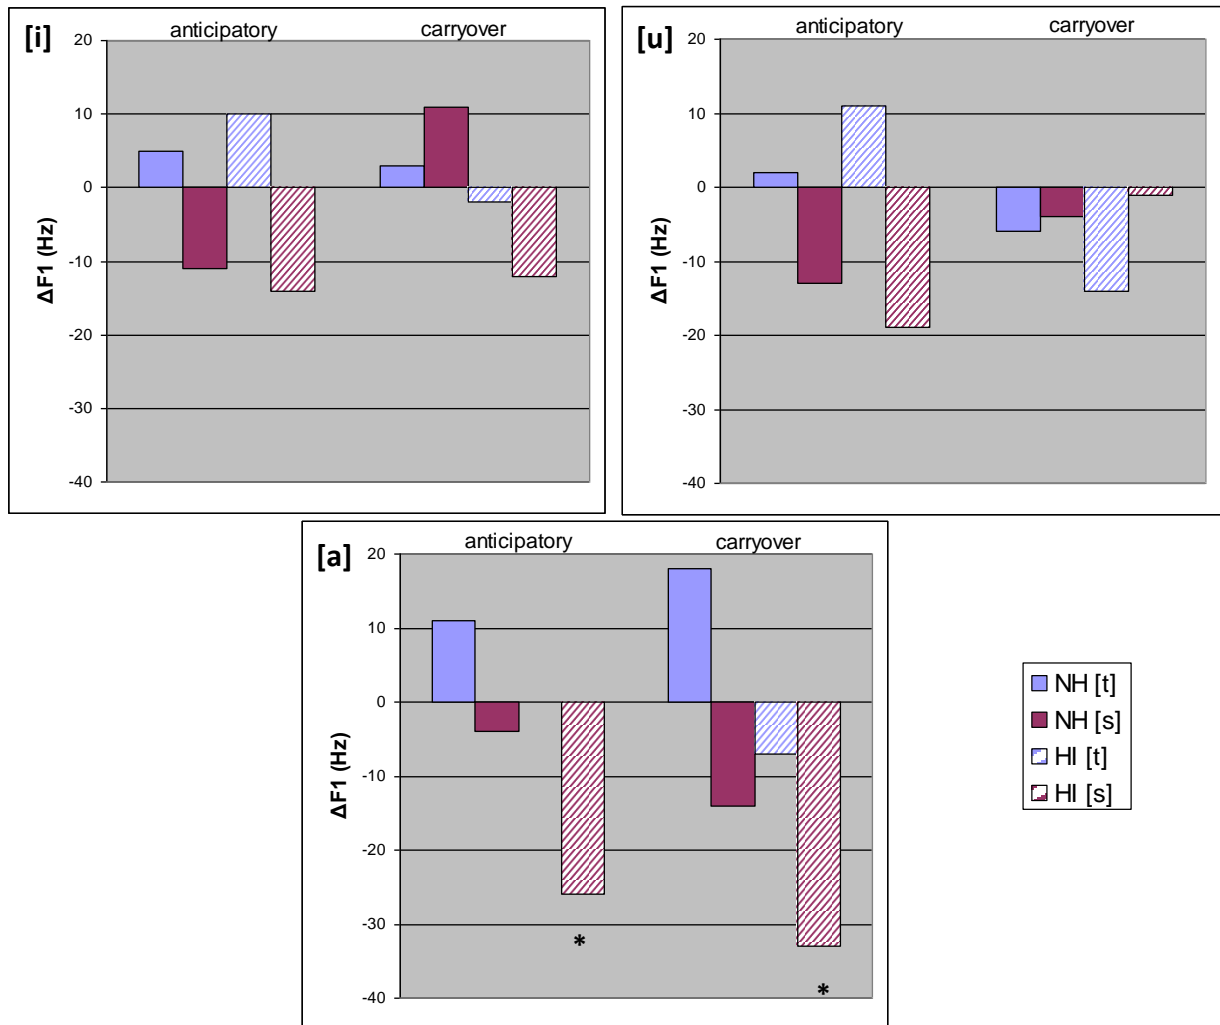

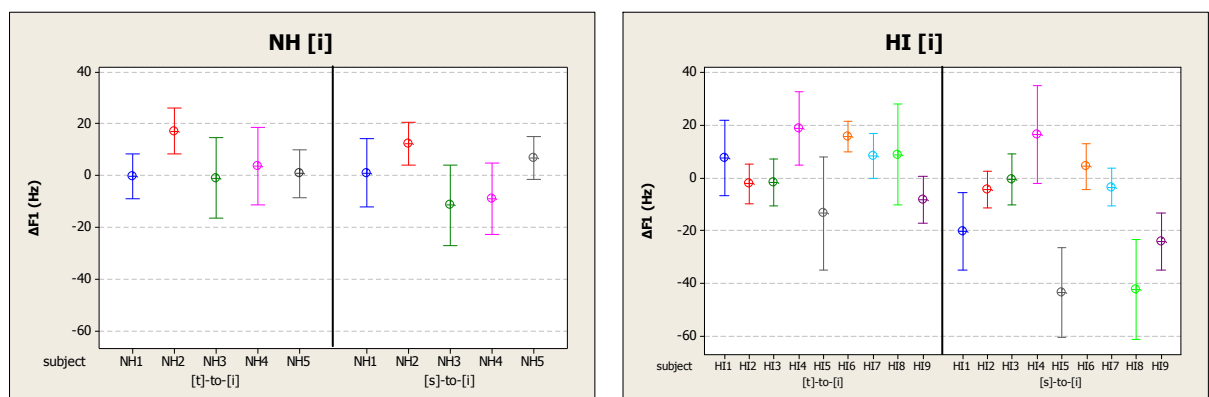

Figure 2 Anticipatory and carryover C-to-V effects from [t] and [s] on the F1 of vowels [i, a, u] produced by the NH and the HI group. The asterisk [*] indicates statistically significant difference from the bilabial context (p<.05)

Variation in F1 C-to-V coarticulation for each speaker based on standard deviation values is illustrated in Figure 3 below. Speakers with HI seem to be more variable overall than speakers with NH. Among speakers with HI, subjects HI1, 4, 5 and 8 display the highest value dispersion.

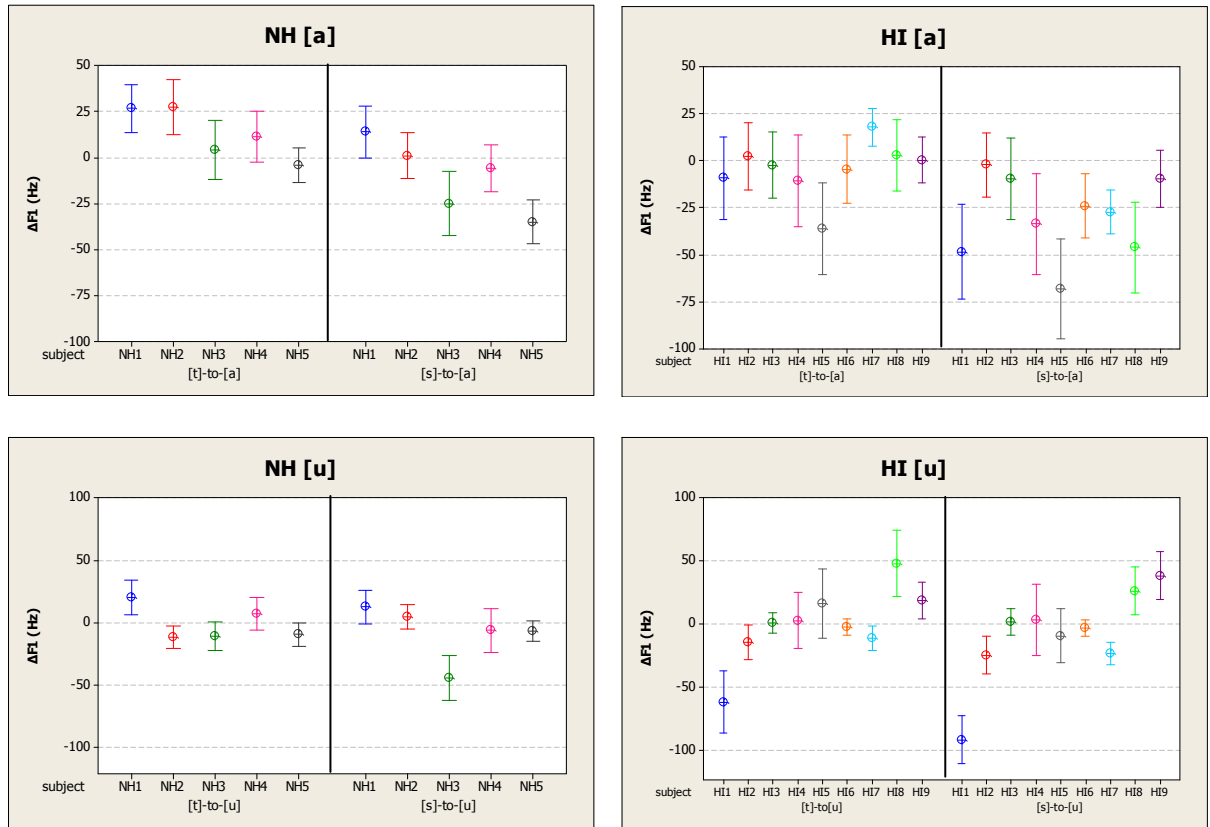

Figure 3 Individual variation of C-to-V coarticulation along the F1 axis displayed by the five speakers with NH (left panels) and the nine speakers with HI (right panels)

3.3 Vowel-to-Vowel Coarticulation

As described in section 2 (Method), V-to-V effects were measured at V_1 offset (anticipatory) and V_2 onset (carryover). The mean F1 difference ($\Delta F1$) in Hz resulting from the subtraction between F1 of the vowel in the symmetrical syllable and F1 of the corresponding vowel in the asymmetrical disyllable is provided separately for the NH and HI group in Table 1. Overall, we note that absolute $\Delta F1$ magnitude is larger for the NH group, especially in high fixed vowel contexts. In the fixed low vowel [a] context, both groups show substantial V-to-V influence over all three consonants, with the HI group surpassing the NH group in absolute influence magnitude in certain cases (i.e., /papa-/papi/, /pata-/pati/, /papa-/papu/, /pata-/patu/). In the two fixed high vowel contexts, effects are overall minimal for both groups, except for the NH group across the bilabial consonant. Coarticulatory variability for the two high vowels seems to be comparable between the two groups, whereas V-to-V effects on the low vowel [a] were found somewhat more variable for the HI group.

direction	fixed [i]	$\Delta F1$ (StDev)		fixed [a]	$\Delta F1$ (StDev)		fixed [u]	$\Delta F1$ (StDev)

4. Discussion

The present study examined selected acoustic characteristics and coarticulation phenomena along the F1 axis in disyllables produced by Greek speakers with hearing impairment (HI) and normal hearing (NH). Regarding the position of the three point vowels [i, a, u] in the acoustic space, HI high vowels [i] and [u] were found to deviate more than the low vowel [a] from normal, as [i] was realized more posteriorly and [u] was fronted and raised in HI speech. Although variable findings concerning vowel errors are reported in the literature, our results agree with studies documenting [u]-fronting (McGarr & Gelfer, 1983) and relatively better low vs. high vowel production in HI speech (Smith, 1975; Geffner, 1975; Gold, 1980). A 36% vowel space reduction was noted mostly due to an F2 range restriction in agreement with previous research (on English: Monsen, 1976b; Rothman, 1976; McCaffrey & Sussman, 1994; on Greek: Nicolaidis & Sfakianaki, 2007).

As far as C-to-V coarticulation is concerned, effects were of small magnitude in NH speech. Similarly, consonantal context does not cause significant variation in the height of NH vowels according to physiological studies on Italian (Farnetani & Faber, 1992) and on English and Swedish (Keating et al., 1994). As expected, the low vowel [a] seems to receive more consonantal influence than the two high vowels, in line with Recasens et al. (1997), since the articulatory distance between the low [a] and the alveolar consonants is greater. This is observed for both the NH and the HI group, although the latter seems to show more pronounced vocalic raising than normal in the environment of the fricative [s]. As mentioned in section 1 (Introduction), more tongue dorsum involvement and palatal contact have been observed via EPG during the production of this consonant by Greek speakers with HI (Nicolaidis, 2004). Consequently, the more sizeable influence observed in our F1 data in the [s] context may reflect a higher jaw or tongue position than normal during HI /pVsV/ sequences. Regarding individual variation, in most cases HI coarticulation displayed higher variability than normal, in agreement with Okalidou (2002) who also found reduced coarticulatory stability than normal for American speakers with HI. Since speakers with HI had been selected carefully so as to have similar clinical profiles, individual differences in coarticulatory magnitude cannot be easily attributed to specific audiological or educational characteristics. We note, however, that the four speakers with HI, displaying the higher coarticulatory variability, also show the most vocalic raising effects. Hence assuming a higher tongue/jaw position than normal during /VtV/ or /VsV/ production could often concur with increased coarticulatory instability.

Regarding V-to-V coarticulation, effects in the fixed high vowel contexts are minimal for the HI group suggesting a more constrained production of [i] and [u] than normal. Effects on the NH high vowels are larger in comparison but reach substantial magnitude only across the bilabial. This outcome is in line with the DAC model (Recasens et al., 1997) which predicts more V-to-V coarticulatory influence across unconstrained consonants, such as [p]. Additionally, for both groups, the low vowel [a] exhibits less coarticulatory resistance compared with the high vowels, in agreement with the DAC model that claims more coarticulatory sensitivity for vowels that involve less tongue dorsum raising (Recasens et al., 1997). More coarticulatory variability in height for the Greek [a] vs. [i] in NH speech has also been documented with EPG (Nicolaidis, 1997), while similar findings have been reported on other languages as well (e.g., Gay, 1974; Keating et al., 1994; Mok, 2011). It is noteworthy that substantial effects on fixed [a] seem to span the two alveolars and especially the fricative, contrary to the predictions of the DAC model, but in line with previous EPG findings on Greek NH speech (Nicolaidis, 1997). A possible explanation is that [s] displays increased variability in Greek NH speech due to the absence of contrastive fricatives in the alveolar region, thus allowing for more coarticulatory effects. V-to-V effects spanning the fricative are not as prominent in HI speech especially anticipatorily, consistent with the hypothesis that the HI fricative has a more constrained production than normal. However, anticipatory V-to-V effects seem to be relatively favoured across the alveolar stop [t] for the HI group which could denote a lower jaw/tongue position during its production compared with that of the fricative, as also supported by our C-to-V coarticulation results.

As regards coarticulatory directionality, the carryover component is relatively more prominent in NH coarticulation. The prominence of carryover vocalic effects across bilabials in NH speech has also been noted by research on other languages and is associated with the slow articulation of the massive jaw (Sussman et al., 1973; Magen, 1997; Recasens & Pallarès, 2000). HI effects follow a more variable directionality pattern depending on consonantal context. Concentrating on V-to-V coarticulation on [a], since effects on the high vowels are minimal, we note that the fricative appears to favour the carryover component, while the alveolar stop displays a slightly stronger preference towards the anticipatory direction. Less consistent prominence of the carryover level in vocalic effects may suggest differential coarticulatory patterning in HI coarticulation. Further statistical treatment of the data may reveal significant differences between NH and HI coarticulation.

5. Conclusions

According to the results of the current study, HI point vowels, and especially the high vowels [i] and [u], display a more restricted F2 and, secondarily, F1 range in comparison with NH vowels. Looking into coarticulatory effects, the fricative [s] was found to induce more vocalic raising than normal probably due to its more constrained manner of production in HI speech. Moreover, the examination of V-to-V effects along the F1 dimension showed that HI high vowels are more constrained in height than normal. Effects on the low vowel [a] are substantial for both hearing groups, although HI effects do not show consistent preference towards the carryover component as occurring in NH coarticulation.

Although the F1 frequency has been regarded as less problematic than the F2 frequency due to its visual and auditory accessibility to speakers with HI, the present data suggest that F1 coarticulation in Greek HI speech shows certain differences from that observed in NH speech. Further analysis of the current data and parallel investigation of coarticulatory effects in the F2 axis may shed more light on the differences between NH and HI coarticulatory patterns, broadening our knowledge on tongue-jaw coordination and interarticulatory organization of speakers with profound hearing loss with data from the Greek language.

Acknowledgements

This study reports preliminary results from a part of the author's doctoral thesis supported by the Greek Ministry of Education, Lifelong Learning and Religious Affairs. I gratefully acknowledge the help of my supervisor Dr Katerina Nicolaidis and co-supervisor Dr Areti Okalidou. Many thanks are due to the participants of the study and the Association of Parents and Guardians of Deaf and Hard of Hearing Children of Central Macedonia.

DUBBING ‘HERCULES’

Charalambia Siristatidou

Δημοκρίτειο Πανεπιστήμιο Θράκης

charasyris@gmail.com

ABSTRACT

This present paper presents a descriptive analysis of the humorous extracts from a children’s DVD movie called ‘Hercules’, a dubbed version of the well-known Greek hero and his labors. The analysis will be based on how successfully humour can be transferred from the source language (English) to the target language (Greek) in terms of cultural references. There will be a taxonomy of the humorous elements as well as culture-specific references in this child-targeted DVD movie based in the classification of jokes of Patrick Zabalbeascoa (1996: 2:2). Drawing on the findings of this pilot study consisting of only one dubbed DVD children’s movie, this paper is aimed to represent the strategies applied when translating cultural and humour specifics.

Keywords: English-Greek, humour, audiovisual translation, dubbing, intercultural communication, culture-specific references

1. Objectives

The objectives of this study are:

- firstly, to represent how humour is translated into the target language with respect to cultural references, translation idioms and equivalence.
- Second, to identify how humour elements could be classified according to Zabalbeascoa’s classification of jokes and whether new types of humour can emerge.
- Third, to list all the humour types, a useful tool for a future research to investigate to what extent they appear/or differentiate from other types of humour found in relevant DVD dubbed movies of Hercules.

1.1 Corpus

For this pilot study, I selected the dubbed movie of ‘Hercules’. The choice of the DVD was determined by the following factors : a) it is very popular b) it includes many humorous elements mostly culture-targeted and language-targeted (the use of slang language is extensive) and c) Hercules is a hero in mythology, known worldwide for his labours. Thus, it would be interesting to describe the humour elements that are presented in English, an international language and how successfully they are transferred into the Greek language through dubbing.

1.2 National –sense of humour joke

In this category, Zabalbeascoa (1996, 2:2) reports that by ‘National-sense-of humour joke I mean that certain joke-types and joke-themes are apparently more popular in some countries or communities than in others and constitute a kind of tradition or intertextual frame of understanding. For example, some communities like to make fun of themselves whereas some others do not and prefer to laugh at somebody else’s expense.’ In the example below, the latter takes place. It would be very interesting to analyse the reasons behind the translator’s choice to use this national joke in a children’s movie.

- Situation: Some young men are playing a game and don’t want Hercules to join them. Thus, they call him ‘geek’.

What a geek!

Translation: Αμερικανάκι

In this example, the word 'Αμερικανάκι' has a negative implication and could be considered a very offensive characterisation for the American culture and nationality. It is inappropriate and considered even to be a well hidden anti-American propaganda as this child-targeted movie will be shown to Greek audience (children above 5 years old and adults as well) who subconsciously will adopt anti-American feelings and in the worst scenario will repeat this expression, which is perceived as a mockery. An alternative translation could be a literal translation, as there is an equivalent that could be used in this case: Τι σπασικλάκι!

1.3 National Cultural-sense-of-humour

With national cultural-sense-of-humour elements, there is a need to find references of the original ones in the national culture of the target languages, in order to retain the humorous effects for the target audience.

- Situation: Panic and Pain, the two assistants of Hades in the underworld are trying to deny that Hercules is still alive.

Every boy was named Jason and the girls were all named Brittany

Translation: όλα τα αγόρια τα βαφτίζανε Παντελή και όλα τα κορίτσια Αγλαΐτσα

The equivalence priority of the translator here was first to produce a comic effect and second to find the most common names in Greek children's literature in order to elicit laughter from children.

1.4 Language-dependent joke

A language-dependent joke is basically a joke that is related to the linguistic functions of the language. In this category, the translator has succeeded in transferring the humorous elements, because Greek and English are closely related in terms of literal meaning.

- Situation: Throughout the whole movie, there are many cases that names are laughter-eliciting.

Jercules - Hunkules

Translation: Χαζοκλή – Τεκνοκλή

1.5 International Joke

The international joke is a humorous word or phrase independent of cultural or linguistic restrictions. There are no language and culture boundaries imposed by any culture. It has to do mostly with the scenario itself and the characters of the movie. Here is an indicative example of an international joke:

- Situation: Zeus is talking to Hades after a long time.

You ought to slow down. You'll work yourself to death.

Translation: Κάνε λίγο κράτει. Δουλεύεις μέχρι θανάτου. (Θα ψοφήσεις στη δουλειά)

2. General Remarks on the analysis of humour in a dubbed movie

We notice that some English words **are not translated**, as the translator considers that they will be understood by the Greek audience, including children. These are some examples: *time out*, *excellent*, *game*, *set*, *match*, *halt*.

It is worth mentioning that in this children's movie **the language is rather colloquial and slang**. Overall, this is happening probably in order to be more easily comprehensible and laughter –eliciting for the audience of children. There are a lot of instances where the names in the source language are very funny for children, such as Mr.High and Mighty being translated as Ο κος Σιγά τ'Αυγά. The translator could find easily the equivalents and there was no humorous effect lost. Some indicative examples are: *Step aside* (κάνε στη μπάντα), *hold it!* (για μισό..), *dude* (φίλε), *now we did it* (όχι, τη βάψαμε), *butt out, buddy!* (σπάσε, μεγάλε).

Unfortunately, in the dubbing process, it is expected that some of the humorous effect will be lost after all. Although in the below example the translator could find equivalence, he/she did not prefer to use this strategy but opted for another one.

- Situation: People of Thebes are complaining to Philoctetes about the power of Hercules due to his failure to protect them from future disasters.

Young man, we need a professional hero, not an amateur.

Translation: Χρειαζόμαστε έναν πραγματικό ήρωα, όχι κάποιον να κάνει το αγροτικό του.

This example is rather an unsuccessful one. Taking into account that the target audience would be children, we should not expect a child to understand the figurative meaning of the word ‘αγροτικό’. A child should not be expected to know that a graduate of medicine in order to complete his/her degree of medicine must spend a training period of one year as a village doctor. So, the children will be rather confused as they will relate Hercules labours to farm work. The joke is lost because the knowledge required to appreciate it should not be possibly expected from the audience. I would therefore suggest the following alternative, which is a word-by word translation.

Translation: Χρειαζόμαστε έναν επαγγελματία ήρωα, όχι κάποιον που είναι ερασιτέχνης.

3. Future Perspectives

It is important to bear in mind that the process of dubbing a DVD is a demanding one, especially when it has to deal with children’s movies.

As I mentioned in the introduction, the findings of this pilot study need further analysis as well as comparison to future studies of other dubbed DVDs concerning the transfer of humour and cultural references.

ABSTRACT

The aim of this paper is to present the findings of a study regarding the students' attitudes to learn Greek as a second language within the framework of Greek intercultural education. It further seeks to explore the relationship of this psychological construct with their level in the Greek language. The findings indicate that to a great extent the students who exhibited integrative and instrumental orientations were the ones of an advanced proficiency level. The paper concludes with pedagogical and teaching recommendations based on the findings and suggestions for further research.

Keywords: attitudes, L2 community, Greek as a second language, intercultural education

1. Introduction

Attitudes are the cornerstone in determining our view of the world. In addition, they are responsible for the shaping of our perception of the world and the response to the various entities around us (Oppenheim, 1998). Due to the key role that attitudes play in our society and lives, it is apparent that the study of attitudes has a long history.

The original impetus for the study of attitudes and motivation can be traced in the grounds of social psychology and namely in the pioneering work of Gardner and Lambert (1972), which paved the way for empirical research into L2 motivational research. Gardner (1985: 6) asserts that "students' attitudes towards the specific language group are bound to influence how successful they will be in incorporating aspects of that language". Thus, favourable affective disposition toward the target linguistic group offers opportunities for greater successful learning outcomes. Research carried out in this field has brought to light findings that corroborate Gardner's position, suggesting that there is a link between proficiency and the attitudes held toward the second language and the L2 community (Gardner, 1985). In particular, Gardner and Lambert (1972) conducted a series of studies which delved into learners' attitude toward the French speaking culture and the possible impact on the learners' motivation to learn the target culture and student achievement. What is prevalent in Gardner and Lambert's (1972) contribution to the study of second language motivation is the distinction between two types of orientation: integrative and instrumental. The former refers to an individual's desire to identify with the members of the speech community, to interact with them and to understand them, whereas the latter denotes the individual's desire to learn the language in order to improve his/her professional status, to pursue studies in that country, or to serve a certain utilitarian purpose. In his socio-educational model, Gardner (1985) identifies that motivation comprises three elements: effort, want and affect, while acknowledging the existence of certain other constituents: 1) the social milieu, (2) individual differences, (3) second language acquisition contexts and (4) outcomes.

The socio-educational model, however, has seen its share of criticism (Dörnyei, 1994, 2001a, 2001b, 2005; Oxford and Shearin, 1994). One of the points raised concerns that the distinction between integrative and instrumental orientation is specific to bilingual settings. Researchers have stressed the need to delve into contexts where English is taught as a foreign language. Results from studies carried out in EFL contexts have suggested that learners show instrumental orientation due to the limited contact with the native speakers or the target culture (Dörnyei, 1990, Oxford and Shearin, 1994, Warden and Lin, 2000). Thus, the impact of the context on L2 learning attitudes and motivation has been greatly stressed in the literature.

Various aspects have attracted researchers' attention by pointing directly to the relationship between second language learners' attitudes towards language learning and achievement behaviour (Ames & Ames, 1984; Csizér and Dörnyei, 2005; Dörnyei, 2000, 2001a, 2005; Guilloteaux, 2007; Lanara, 1999; Zimmerman and Schunk, 2001), parental influence and support (Gardner, 1985; Kormos, Kiddle and Csizér, 2011) and the age of learners (Muñoz and Tragant, 2001; Nikolov, 1999; Sougari and Iliopoulou, 2011).

Previous research has highlighted the basic constituents of attitudes towards L2 learning. Even though the findings (Wenden 2001; Hurd 1998; Cotterall 1995) that stress the correlation between attitudes and learning outcomes abound, there is still no sufficient information regarding how learners of different proficiency levels respond to the target linguistic-cultural group within the second language context. Thus, this study aims to contribute to the on-going research in the field of attitudes and motivation to learn Greek as a second language in a truly intercultural setting where Greek is both the subject taught and the medium of instruction in all subjects within the school curriculum of an intercultural lower secondary school.

1.1 Intercultural education in the Greek education setting

During the last three decades, Greece has experienced an immigration flow that has significantly changed the characteristics of the population; most changes are apparent on the social, economic, racial, ethnic, educational and religious level. The impact on the educational level cannot be underestimated as this particular sector has been called to respond to the great diversity present in the classroom. Thus, in light of the fairly recent situation, the Greek education system has experienced various changes in order to respond to the demands of society (Triandafyllidou and Gropas, 2007).

In the early days (1990s), reception classes (made up mainly by repatriates and their descendants and other foreign nationals) were arranged with a view to addressing the various educational, cultural and linguistic needs of newcomers. In the mid 1990s, a comprehensive legislative framework was put forward and the foundations for intercultural education were set (Law 2416/65). Since then, 26 intercultural schools have been established as a special category of schools; in these schools, reception classes for students who have little or no prior knowledge of Greek are also hosted. Even though there is no curriculum developed to specifically address and respond to the needs and knowledge of this student population, intercultural schools rather follow the mainstream curriculum of regular ones; in these schools, the teachers are asked to cater for the individual needs of the students.

2. Research methodology

2.1 Aim of the study and research questions

This study reports on the findings based on a questionnaire survey that investigated lower secondary students' attitudes studying Greek as a second language in an intercultural education setting. The results of a previous study (Sougari and Iliopoulou, 2011), which investigated the same student population, focused on delineating the students' motives on learning Greek as a second language. The conclusion drawn from that study highlighted that the students were not integratively- but rather instrumentally-motivated. Thus, it was considered important to investigate further these students' attitudes in order to examine the impact that the proficiency level has on their orientation. With a view at unraveling the attitudes that these students espouse so as to design a course that is tailored made to their needs, certain questions need to be addressed:

1. What is the impact of the students' level in Greek on their attitudes toward the Greek language?
2. Is there a relationship between proficiency level and the type of attitude held by second language learners within the framework of intercultural education?

2.1.1 Participants

To gain a better understanding of second language learners' attitudes toward the Greek language and the Greek situational context, the study focused on whether there is a relationship between the students' proficiency level, while following the practices of an intercultural lower secondary school and their attitudes towards the language in general. As regards the participants, 99 students took part in this study, while being equally distributed in the three grades of the lower secondary school, that is, 1st

grade: N=33, 2nd grade: N=33 and 3rd grade: N= 33. The study was conducted toward the end of the school year so as to ensure that all learners had adequate experience with the Greek language and the Greek style of living. Upon enrolment in the school, the students sit for the National Certificate in Greek (even though there is no official approval regarding this procedure) and subsequently are placed to the appropriate group according to their placement (i.e. beginner, intermediate and advanced). Thus, based on the students' differentiation in terms of their proficiency level, we can discern the following pattern: 1st grade: Beginners – 35%, Intermediate – 30% and Advanced – 35%; 2nd grade: Beginners – 26% and Advanced – 74%; and 3rd grade: Beginners - 29% and Advanced – 71%). With particular reference to the country of origin, the sample reflects great diversity: the majority of the students come from Albania and Georgia, being 23% and 22% respectively, whereas to a lesser extent they originate from countries such as Afghanistan (17%), Russia (9%), China (8%), Skopje (6%), Mauritania (4%), New Guinea (2%) and various other countries (9%). The sample consisted of 67% male and 33% female students; the higher presence of male students reflects the higher migration rate of males, while their families remain in their country of origin. In addition, the participants' age ranges from 13 to 18. Prior schooling received is a parameter that is acknowledged upon allocation and that is why older students such as Afghani have been allocated to the lower secondary school due to their enrolment up to the primary sector in their country of origin.

2.1.2 Data collection instrument and data analysis

Second language learners' attitudes toward the Greek language and the Greek cultures were captured with the help of an adapted version of the questionnaire proposed by Dornyei, Csizer and Nemeth (2006), which originally aimed at investigating second language learners' attitudes towards various target linguistic groups. The questionnaire was pilot tested and various changes were implemented in order to make it appropriate for the given situational context, bearing in mind the need to render the questionnaire accessible to the learners of all proficiency levels. Thus, particular attention was paid to the wording of each statement. In the case of beginners, the same questionnaire was administered in an English version so as to cater for those learners who could be regarded as low proficiency learners in Greek but had good prior knowledge in English. The questionnaire was administered to the students in class so as one of the researchers to be available for further clarification.

With specific reference to the various items of the questionnaire, it should be mentioned that the questionnaire is divided into three parts: part A elicits the bio data of the participants which allowed for the sketching of the learners' profile, namely: age, gender, country of origin, mother tongue, parents' knowledge of Greek, years of residence in Greece, knowledge of other languages, etc.; part B delves into the problems learners encounter when learning Greek and how they cope with them; and part C examines learners' attitudes towards the Greek language, the Greek culture, the language community, their disposition to seek employment in Greece and their desire to use Greek in their communication exchanges. The statements in Part C are replied in the form of a 5-point rating scale where 1 stands for strongly disagree, 2 for disagree, 3 for neither agree nor disagree, 4 for agree and 5 for strongly agree.

As regards the statistical analysis, the data underwent processing while adopting the Kruskal Wallis test, the non-parametric test, which is performed on ranked data by reflecting the relative strength of the variability in the ranks among the three possible conditions (i.e. beginners, intermediate and advanced). In the case where two independent samples (i.e. beginners and advanced) were present, the Mann Whitney U test was applied in order to determine if a difference exists between the two groups. The significance level was set at <.05.

3. Results

The present study focuses on students' attitudes that learn Greek as a second language by seeking whether there is association between their attitudes towards the Greek language and the Greek target-linguistic group and their overall proficiency in Greek. The results are looked upon with a view of delineating two sets of attitudes: namely, the integrative and instrumental orientation based on Gardner and Lambert's distinction (1972).

3.1 In search of students' integrative orientation

In the literature, integrative orientation has been regarded as the most crucial factor in motivating an individual to strive towards successful learning outcomes. To what extent is the learners' level of proficiency in alliance with their desire to identify with the target group and their appreciation of the various cultural activities? Thus, this study attempts to uncover second language learners' attitude toward their desire to assimilate in the host country and disposition towards the Greek language and the Greek cultural artifacts.

Statement 1: I would like to live in Greece

In reply to this statement, those students attending the first grade in the lower secondary intercultural school showed quite different ratings of their future plans as regards their desire to reside in Greece. There was no agreement among the three proficiency levels and that is why a significant difference emerged. It also becomes apparent that the beginners gave a higher mean ranking than the other two groups. In the case of the 3rd graders, it can also be deduced that the mean ranks that beginners reported are much higher than those of the advanced group, thus indicating a significant result (see Table 1).

	Attitude	Level ¹	1 st grade K W ²			2 nd grade MW U ³ test			3 rd grade M W U test		
			MR ⁴	M ⁵	<i>p</i>	MR	M	<i>p</i>	MR	M	<i>p</i>
1	I would like to live in Greece	B I A	22.08 21.44 8.58	4.83 4.78 3.33	.000	16.88 17.04	4.00 3.84	n.s.	22.00 13.75	5.00 4.40	.003

Table 1 Learners' integrative orientation

¹ B: beginners, I: intermediate, A: advanced, ² K W: Kruskal Wallis,

³ M W U test: Mann Whitney U test, ⁴ MR: mean rank, ⁵ M: mean

Statement 2: I like Greeks

The respondents' reaction to this statement revealed that first graders across the various levels showed very distinct attitudes towards their positive orientation towards Greeks, thus, reflecting completely disparate views. It appears that intermediate students ranked this much higher in their priorities than the other two groups. Support for this statement is evident in 3rd graders' responses, while advanced learners tended to give a higher mean ranking than their beginner counterparts (see Table 1).

Statement 3: I would like to identify with Greeks

In Table 1, significant findings highlight students' attitudes towards their desire to identify with Greeks. Bearing in mind the age of the respondents and the fact that their contact with the people in the host country was not made available until their adolescence, the respondents' reaction to this statement brings to light quite contradictory results, rendering the deduction of specific conclusions quite impossible. First graders showed significant differences in their mean rankings, with intermediate

students giving higher mean ranking in their priorities against the rest of their classmates. In the case of second graders, beginners gave a higher mean ranking than the advanced group, whereas in the case of third graders, the advanced learners appeared to give a higher mean ranking than their beginner counterparts.

Statement 4: I like the Greek language

A look at Table 1 makes quite apparent that the students belonging to the various proficiency levels of each grade showed quite different attitudes as encapsulated in their responses. Significant differences emerged in all cases indicating that more advanced students reported a higher mean ranking of their attitude toward the Greek language. Only in the case of the first graders did the intermediate group offer a higher mean ranking than the other two groups.

Statement 5: I like the Greek culture

In the case of the three proficiency levels in Grade 1, the intermediate group exhibited a higher mean ranking than the other two groups in response to the statement: 'I like the Greek culture'. More favourable attitudes emerge on the part of the advanced group of Grade 2 who differentiated from their beginner counterparts. As far as the students attending Grade 3 are concerned, they displayed similar attitudes and no significant differences emerged.

Statement 6: I like Greek films

The response to this statement brings to light similar attitudes as the ones presented in the previous statement. Advanced learners belonging to the second and the third grade responded in favour of Greek films, while giving quite distinct answers in relation to those provided by the beginner group in the respective grade. Once more, with particular reference to the first graders, the students attending the various proficiency-leveled classes showed quite different replies and significant differences emerged, while revealing that intermediate students offered a higher mean ranking than the rest.

Statement 7: I like Greek music

Similar to the previous statement, significant differences appeared in the case of first graders with the intermediate group professing to like the Greek music more than the rest of their counterparts. The difference between beginners and the advanced group among second graders is statistically significant, whereas among third graders a non-significant result was rendered, revealing similar attitudes towards Greek music.

3.2 In search of students' instrumental orientation

The following set of statements pertains to the sphere of instrumental orientation which relates to a person's attitude toward learning the Greek language while striving for the attainment of certain utilitarian goals, such as satisfying a job prospect, obtaining a proficiency certificate and achieving communication goals.

Statement 8: I would like to find a job in Greece

As regards the desire to satisfy future occupational activity, first graders showed quite distinct attitudes, where beginners gave a higher mean ranking to this priority, showing that this is one of their main goals. Statistical significant results surfaced in the case of the students comprising the two groups (i.e. beginners and advanced) of second and third graders. However, in the former, the advanced group offered a higher mean ranking, whereas in the latter, beginners were more in favor of finding a job in Greece (see Table 2).

	Attitude	Level ¹	1 st grade K W ²			2 nd grade MW U ³ test			3 rd grade M W U test		
			MR ⁴	M ⁵	p	MR	M	p	MR	M	p
8	I would like to find a job in Greece	B I A	21.17 17.28 12.68	4.83 4.56 3.17	0.41	11.50 2.62 18.76	3.96	.045	21.50 5.00 14.08	4.05	.006
9	I would like to attain a certificate	B I A	26.50 13.61 10.04	5.00 3.22 2.42	.000	20.94 4.38 15.74	n.s.		22.00 5.00 13.75	4.20	.003
10	I wish to communicate with my classmates	B I A	8.38 20.50 23.00	1.92 3.33 3.67	.000	11.25 2.25 18.84	.044		10.15 2.00 21.45	3.70	.001
11	I wish to communicate with my Greek friends	B I A	10.79 23.83 18.08	1.92 3.67 2.67	.003	14.62 3.25 17.76	n.s.		7.69 1.69 23.05	4.15	.000

Table 2 Learners' instrumental orientation

¹ B: beginners, I: intermediate, A: advanced, ² K W: Kruskal Wallis,

³ M W U test: Mann Whitney U test, ⁴ MR: mean rank, ⁵ M: mean

Statement 9: I would like to attain a certificate

Support for this statement can be found in the case of the groups which constitute the first and the third grade. In both instances, beginners allotted a higher mean ranking to this statement than their counterparts. With reference to second graders, no significant differences can be discerned as the members of this grade exhibited similar attitudes towards the pursuit of certificates as they regarded it equally important.

Statement 10: I would like to communicate with my classmates

Table 2 presents lower secondary learners' attitudes towards their wish to learn Greek in order to establish successful communication exchanges amongst the classmates. The significant differences that were yielded indicate the differences in students' attitudes across all three grades and within the various groups. To be more specific, in all cases, advanced learners wished to use Greek in their classroom interactions in order to converse with the members of the class who have different mother tongues. Thus, Greek is regarded as the medium of communication to satisfy the need to establish interpersonal relations inside and out-of-class interactions.

Statement 11: I would like to communicate with my Greek friends

First and third graders seem to hold quite different views within their groups. Thus, while looking at the former, we can discern that intermediate students once more gave a higher mean ranking than the rest, whereas in the case of the latter, advanced learners displayed a similar attitude. This could lead to an understanding of the students' incentive to use Greek in order to satisfy their communication exchanges with members of the target linguistic group.

4. Discussion and concluding remarks

In order to probe second language learners' attitudes towards Greek as a second language within the intercultural education setting, particular attention was paid to the impact that their proficiency level could have on their attitudes. The previous study by Sougari and Iliopoulou (2011) on uncovering second language learners' motives for learning Greek as a second language failed to report substantial signs of integrative orientation among the members of the three grades, while suggesting that this could be due to their age at the time of arrival in the host country. It seems that older learners resist integration into the speech community in their attempt to retain their self-identity. However, in the present study an examination of the data with respect to the students' proficiency level revealed that favourable attitudes towards the language community are held by those students whose competence in the second language is higher than those who have a lower proficiency level. What could be accounted for is that the make-up of individual classes by certain ethnic groups could very well have to do with how they respond to otherness and the cultural values of the host community. That is why, to a great extent, as regards the intermediate group in Grade 1, they seem to be more positively predisposed to the Greek reality. It

becomes evident that the integrative orientation towards learning the language that students have affects other aspects of their everyday life as well. What is worth mentioning is that quite proficient students show appreciation for the Greek culture, music and film. Therefore, it comes as no surprise that these students also express their positive disposition towards the target speech community of the host country. It appears that the proficiency level plays a key role in determining and instilling positive attitudes and allows students to develop their integrative orientation.

Students of a higher proficiency level pursue communication exchanges in in-class discussions or in their encounters with their Greek friends. It appears that the students of a more advanced proficiency level are more confident to engage in conversations, whereas the rest lack even the necessary self-confidence to interact with their classmates. Consequently, the absence of satisfactory communication with the people in their surroundings does not allow the low proficiency students to practise using the language, to develop relationships and to come into contact with their classmates and other members of the speech community. This vicious circle is counter-productive as the lesser the contact, the lesser the practice and the lesser the appreciation of the host culture and its members. However, what springs from the results in this study is that the students of a low proficiency level show a greater desire to tie up their future with the host country, that is, Greece in this case. In connection to this, they also express that the studying of Greek will serve certain utilitarian purposes; to follow an occupational activity in Greece as well as to sit for a proficiency certificate. Thus, even though low proficiency students do not have a strong integrative orientation, they seem to be instrumentally-oriented.

Once the hurdle of communication is overcome, through various challenging classroom tasks so as to make them favourably predisposed to the pursuit of communication encounters, only then can low proficiency students be integrated into the language community of the host country. Bearing in mind that the findings of the previous study (Sougari and Iliopoulou, 2011) highlighted the students' low motivation level, it becomes pertinent to consider the options available to make students integratively-oriented. Providing intercultural education could be a quite challenging endeavour on its own. Once taking into account the array of opportunities available to the teacher, s/he could alter students' dispositions so as to render them into equal members in the host country.

The results of this study bear implications for the teaching and learning a target language within a second language educational context and what is more within an intercultural education setting. As rightly stated by Triandafyllidou and Gropos (2007: 4), what is needed is to "redefine the objectives, methods and approaches of educational policy" and to host "mother tongue courses and classes on history and culture of country of origin"; these are considered quite important with the framework of intercultural education. It is important to bear in mind that "intercultural education involves not only intercultural exchange and knowledge of other cultures but also a reconsideration of the ingroup culture through the integration of culturally diverse pupils into a cohesive societal whole" (Triandafyllidou and Gropos, 2007: 5). Thus, the role of the teacher in the exploitation of cultural artifacts and the cultivation of positive attitudes should not be underestimated as s/he is the sole mediator of providing filtered information in the classroom setting and the facilitator in his/her attempt to assist his/her students to become autonomous learners and members of the host country. Some practices that the teacher could adopt are the following: (i) adoption of innovative practices, such as differentiated instruction which responds to individual learner needs and the cross-curricular approach, (ii) promotion of project work, which allows students to incorporate elements of their own culture, while working at their own pace, (iii) incorporation of group work in an attempt to instill collaboration and interaction among the members of the class, and (iii) implementation of multi-model texts, enabling even students with limited or no knowledge of the target language to engage eagerly in activities. The above mentioned suggestions do not entail rejection of the curriculum but rather an adaptation of the curriculum to the needs and interests of the students. What is important is to consider ways in which the diversity of the class could promote an understanding of otherness, a feeling of belonging, an appreciation of diverse cultural artifacts

The implementation of innovative practices is likely to encounter various hurdles, particularly on the part of traditionally-oriented teachers who fail to appreciate the impact of an innovation on learners' attitudes and learning outcomes. Future research should address teachers' response to the intercultural challenge and to the innovations that should be implemented in the intercultural classroom setting. Once teachers recognize the value of incorporating certain practices in their teaching and are properly trained, intercultural education will affect positively the attitudes and lives of second language learners. Impact of their nationality

THE DEVELOPMENT OF NARRATIVE STRUCTURE IN GREEK L1

ABSTRACT

The present study seeks to investigate how 7, 9 and 12-year-old Greek-speaking children differ in their ability to encode the temporally ordered events of a story as constituents of narrative structure. The research was conducted on the basis of a written, picture-elicited narrative. The results show that 7 and 9-year-olds show a tendency not to mark the causal relations between events, but to produce linear narratives with local temporal discourse organization. 12-year-olds begin more systematically to encode causal relations between events and episodes of the story. The ability, however, to produce complete episodes which are hierarchically organized appears as fully developed only in adult narratives. These results indicate that global-level mastery of narrative discourse organization still develops after the age of 12.

Keywords: L1, narrative development, discourse, narrative structure

1. Introduction

The acquisition of the grammatical system of any native language is considered to be completed by the age of 5 years. However, language development still continues after the age of 5. Along with the acquisition of a number of complex grammatical structures (e.g. passive constructions, relative clauses etc) and the development of vocabulary, there is evidence that important changes take place in later language development. Many researchers (Karmiloff-Smith 1979; 1986; Berman and Slobin 1994; Hickmann 2003) have demonstrated that even simple linguistic structures, such as determiners, undergo changes in their use during the transition from the local intrasentential to the global intersentential level of discourse. Thus, it seems that an important aspect of late language development is associated with the organization of utterances in long spans of connected discourse, which involves the reorganization of the already mastered linguistic structures in order to express new functions at the discourse level.

The present study concerns late language development, as it examines the development of the ability to create global narrative discourse organization in Greek-speaking children 7-12 years of age. The main objective of this study is to investigate how, with increasing age, children differ in their ability to produce coherent narrative discourse, i.e. to encode the temporally ordered events of a narrative as constituents of narrative structure.

1.1 Narrative discourse

Narrative, as the most common form of extended discourse, is the text type that has mainly been studied with respect to late language development. Narrative discourse has some distinctive characteristics in relation to other text types. The first characteristic is the temporal sequence of events. Labov and Waletzky (1967, 28) define narrative as “any sequence of clauses which contains at least one temporal juncture”. Accordingly, Smith (2003, 14) describes narrative mode as advancement in narrative time. This advancement is based on sequence, since the events of the narrative are being perceived as occurring one after the other.

However, the temporal sequence of events, although a necessary condition to characterize a text as a narrative, is not enough. Another criterion for the classification of a text as a narrative is the existence of a “deviation” or “complication” in the normal and expected course of events, which causes a series of events aiming at restoring the initial equilibrium state (Todorov 1968; Bruner 1991, 11). Therefore, besides the relation of temporal succession between events, narrative is also characterized by causal relations between one or more events.

Finally, another important dimension of narrative discourse is its high degree of decontextualization. Narratives can be abstracted from the immediate situational context and can stand on their own, since their production does not necessarily require the involvement or mediation of an immediately present addressee (Benveniste 1966; Toolan 2001, 226). For this reason, narrative discourse production triggers decontextualized linguistic choices; typical extralinguistic elements (for instance, deictics) exhibit intralinguistic functions.

1.2 Narrative structure

Research on narrative structure has aimed at providing principles or rules to capture the general properties of structurally well-formed stories. Two main approaches and two influential models, respectively, have been proposed: the story grammar model (Rumelhart 1975; Thorndyke 1977; Mandler and Johnson 1977; Stein and Glenn 1979; Trabasso, van den Broek and Suh 1989) and the Labovian model (Labov and Waletzky 1967; Labov 1972).

The present study employs the Causal network model of Trabasso, van den Broek and Suh (1989), which belongs to the tradition of story grammars. According to this model, the content of each clause in a story can be classified into one of six categories: *Setting*, where the main characters, the time and the place of the story are introduced, *Event*, which sets up a problem for one of the main characters, the character’s *Internal Response* to this event (i.e. perceptions, emotions, cognitions, beliefs etc), which evokes a *Goal* motivating an *Attempt* to solve the problem, and the *Outcome* of this attempt. These categories form an episode.

Trabasso, van den Broek and Suh (1989) showed that the structural components of episodes and the episodes themselves can be linked by causal relations in a causal network representation of any given story. The six categories of information are connected to each other with causal relations in multiple ways. These relations reflect the causal logical inferences made either by the recipient during story comprehension or by the narrator during story production. The Causal Network Model is illustrated in Figure 1. The arrows connecting the categories represent the causal relations between them:

Figure 1 Causal network model (Trabasso, van den Broek and Suh 1989)

The Causal network model has been applied to the study of story production on the basis of a picture series (Trabasso and Nickels 1992; Trabasso and Rodkin 1994). Trabasso and Rodkin (1994, 87) point out that the narration of a picture-elicited story is a joint process of event interpretation and language production. This process involves prior knowledge or interpretation, through logical inferences, of the sequence of pictured events and the relations that link the events together. This interpretation is constrained by the degree to which the narrator recognizes the protagonist’s plan aiming to resolve a problem and, subsequently, encodes the protagonist’s actions in a way consistent to this plan. Thus, the creation of a complete and coherent story results from the coherent representation of the sequence of the depicted events, which requires the ability to make logical inferences that link the events into episodes and also link episodes by causal relations.

1.3 The development of narrative structure

From a developmental perspective, studies focusing on narrative structure have examined children’s productions in spontaneous (personal or fictional) or picture-elicited narratives (Botvin and Sutton-Smith 1977; Applebee 1978; Stein and Glenn 1982; Stein 1988; Peterson and McCabe 1983; Hudson

and Shapiro 1991; Berman and Slobin 1994; Trabasso and Nickels 1992; Trabasso and Rodkin 1994; Shapiro and Hudson 1997). These studies show a gradual development of narrative structure from about 3 to 12 years, while children demonstrate global-level organization of narrative discourse much later than the acquisition of the grammatical system is completed, between ages 9-12.

What is considered as an important factor for the development of narrative structure is the hierarchical organization of narratives around a character's goal-attainment plan. According to the findings of previous research, with increasing age children produce stories of greater structural complexity: they advance from the production of simple event sequences to the production of complete episodes which are hierarchically organized. Production of complete episodes is characterized by the implicit or explicit encoding of characters' motives, causally connected to the actions they perform and their outcomes.

1.4 Objectives and research questions

Developmental studies on narrative structure in bilingual children provide evidence that the development of narrative structure is largely language-independent (Kupersmitt and Berman 2001). However, investigating narrative structure in a particular language, such as Greek, where little research has been conducted on narrative development, serves some additional objectives, besides the study of the development of narrative structure *per se*. The main objective of the present study is to provide developmental evidence for children's ability to construct narrative structure in Greek, which can complement evidence from ongoing research on the development of specific linguistic phenomena at the discourse level, such as anaphora, temporality etc.,

The present study seeks to investigate children's ability to organize the events of the story into a series of episodes consisting of a number of structural components and episodes in a hierarchical macrostructure. To this end, the study examines different aspects of the ability to construct narrative structure, on the basis of the following research questions: How Greek-speaking children differ in their ability to encode: a) the events of the story as structural units of episodes, b) characters' actions as attempts to attain a goal, c) the causal relations between the episodes of the story?

2. Method

2.1 Sample

The study is cross-sectional. The Greek-speaking subjects are primary school pupils. The sample consists of four age groups, 7, 9, 12 years-old children and adults, with 20 subjects each (Table 1). Adults were included in the sample as a control group, representing a developmental stage where linguistic and cognitive development are complete. This age group also allows the investigation of whether the ability to create narrative structure is still developing after the age of 12.

Each age group comprises equal number of male and female subjects. All children come from families of middle socioeconomic status and during the period of data collection they were enrolled in primary schools of Athens and Alexandroupolis¹. Adults were 25-40 years old, middle-high SES.

Speakers of Greek		
Age	No of subjects	
	Male	Female
7	10	10
9	10	10
12	10	10
Adults	10	10
Total	40	40

Table 1 The sample of the study

¹ The children enrolled in primary schools of Alexandroupolis consisted part of the monolingual control group of the research project "Assessing language proficiency of the Muslim minority children in Thrace", conducted during 2003 as part of the "Education of the Muslim Minority Children" Programme of the Greek Ministry of Education (see Tzevelekou *et al.* 2008 for details).

2.2 Elicitation material and procedure

Narratives were elicited on the basis of a picture series, which is an adapted version of the “cat story” picture series originally designed by Maya Hickmann (Hickmann 2003). The “cat story” comprises 6 pictures, which depict a short, simple story (Appendix I): Mother-bird leaves the nest to bring food to her little birds. A cat comes by and attacks the birds, while a dog pulls the cat down and chases him away.

Elicitation procedure was held at children’s schools, into their classrooms during school hours. Subjects were given the “cat story” in a single-page sheet and were asked to write down the story they see in the pictures. Particular emphasis was given to the elicitation conditions, in order to ensure that the subject and the researcher do not share mutual knowledge of the story and that the elicited text belongs to the expected text type. To this end, oral instructions specifically stated that the story addressee would not have the pictures available, so he/she should understand the story without any reference to the elicitation material. In this way, students were encouraged to produce narrative discourse, rather than the description of individual pictures, as well as a decontextualized story, i.e. a story that would not contain any deictic elements.

2.3 Transcription, annotation and analysis

Stories were transcribed and annotated using the CLAN program of the CHILDES system (MacWhinney and Snow 1985). Data transcription followed the conventions of the CHAT program, adapted to the characteristics of Greek on the basis of the transcription system proposed by Kati and Kantzou (2001).

For every parameter of narrative structure under study, a particular annotation scheme was created. The criteria used for the development of the individual annotation schemes are described in the respective subsections of section 3 (*Results*).

Data were statistically analyzed in order to identify the statistically significant differences between the different age groups. To this end, the non parametric *U* test (Mann-Whitney) was applied.

3. Results

3.1 Episodic structure

The first research question addresses children’s ability to create episodes which contain a number of structural units. On the basis of the Causal network model of Trabasso, van den Broek and Suh (1989) (see section 1.2), the content of each clause of the story was classified into one of the six categories of episodic structure: *Setting*, *Event*, *Internal Response*, *Goal*, *Attempt* and *Outcome*. The following general criteria were applied for annotating a clause as belonging into one of these categories: a) *Setting*: verbs in Past Imperfective (Paratatikos) (e.g. *there was*, *was sitting*), indefinite NPs introducing characters (e.g. *a mother-bird*), adverbials of place (e.g. *on a tree*), b) *Event*: presentational structures, action or motion verbs (e.g. *came along*, *showed up*, *approached*, *climbed*), c) *Internal response*: lexical elements expressing characters’ cognitions, emotions and beliefs (e.g. *he understood*, *he was aware*), d) *Goal*: volitional verbs, embedded clauses of purpose (e.g. *he wanted to eat them*, *to protect the nest*) e) *Attempt*: verbs expressing attempt or effort (e.g. *tried*) f) *Outcome*: lexical elements expressing success or failure (e.g. *fortunately*, *unfortunately*, *he did it*).

The ability to create episodes is measured by the number of units of episodic structure contained in the stories produced. The distribution of the six categories of episodic structure in the stories of the four age groups is shown in Chart 1. All structural units of episodes are included in the stories of all age groups. This indicates that children of all ages are able to construct episodes which contain basic structural components. However, there is a difference between adults and children of all age groups. The results show that the most frequent unit in children’s stories is *Event*. Events are characters’ actions which are not causally connected to other events of the story, but they are presented one after the other in a linear way, forming event sequences. This finding suggests that children’s stories of all age groups are characterized by local narrative discourse organization. This is also a first indication that construction of complete episodes is not systematic until the age of 12. In example 1, which comes from a story of a 7 year-old child, events are presented one after the other in the form of sequence and they are connected with temporal relations.

Adults' stories contain significantly less Events than all children age groups (7y-adults: $U=69$, $p=0.000$, 9y-adults: $U=114$, $p=0.020$, 12y-adults: $U=118.5$, $p=0.027$). This finding suggests that the ability to construct complete episodes is still developing after the age of 12. Only adults have gone beyond the stage of forming event sequences and they systematically encode events as units of episodic structure (example 2).

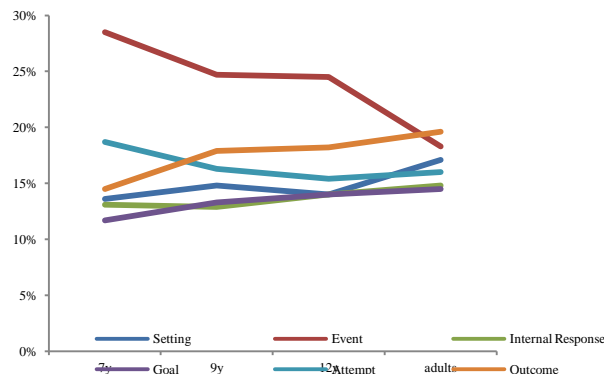

Chart 1 Structural units of episodes by age group

- (1) Όταν έφυγε η μαμά η γάτα σκαρφάλωσε επάνω στο δέντρο. Μετά ήρθε ένας σκύλος. Μετά από λίγο γύρισε η μαμά τους με το φαγητό. Μόλις σκαρφάλωσε η γάτα στη φωλιά ο σκύλος την τράβηξε από την ουρά.
'When the mother left the cat climbed up the tree. Then a dog came along. After a while their mother came back bringing food. Once the cat climbed to the nest, the dog pulled him down by the tail.' (7y)
- (2) μια γατούλα πλησίασε το δέντρο που βρίσκονταν τα παιδιά της (E). Τα κοίταζε με ενδιαφέρον (IR) γιατί μάλλον ήθελε να τα φάει (G). Αφού η γατούλα σιγουρεύτηκε ότι η Σίσυ είχε απομακρυνθεί ανέβηκε στο δέντρο (A) για να φάει τα πουλάκια. Την ώρα που ανέβαινε όμως εμφανίστηκε ο πιστός φίλος της Σίσους ο Μπόμπος σκύλος και τράβηξε τη γατούλα από την ουρά την κατάλληλη στιγμή πριν αρπάξει η γατούλα τα πουλάκια (O).
'a cat approached the tree with the bird nest (E). He was staring at them (IR), because he probably wanted to eat them (G). When the cat made sure that Sissy was away, he climbed up the tree (A) to eat the little birds. But, while he was climbing, Sissy's loyal friend, Bobo the dog, came by and pulled the cat down just before the cat catches the little birds (O).' (adult)

3.2 Characters' attempts to attain a goal

The second research question concerns children's ability to infer and appropriately encode characters' plans to attain a goal, establishing causal relations between goals and attempts. According to the Causal network model, understanding the underlying goals which motivate characters' actions is a key condition for the creation of a complete and coherent episode (Trabasso, van den Broek and Suh 1989).

Every utterance that refers to actions taken by the story characters was annotated either as an attempt to attain a goal or as a simple action without an explicitly or implicitly expressed goal. In the "cat story" there are three cases of such actions and their respective goals (in bold): a) mother-bird is leaving the nest **to bring food to the little birds**, b) the cat is climbing the tree **to eat the little birds**, c) the dog is attacking the cat **to push him away / to rescue the little birds**. The criteria used for annotating an action as an attempt to attain a goal belong to two categories: a) grammatical or lexical means which explicitly state a character's goal (e.g. embedded clauses of purpose, volitional verbs), b) pragmatic and evaluative elements implying a goal, without it being explicitly stated (e.g. *the faithful dog*, *the dog who always chases the cat* etc).

Chart 2 shows the percentages of actions encoded as attempts to attain a goal and simple actions without an underlying goal, appearing in the stories of the four age groups. The results show that adults encode characters' actions as attempts to attain a goal more frequently than all children age groups (7y-

adults: $U=77.5$, $p=0.001$, 9y-adults: $U=74.5$, $p=0.000$, 12y-adults: $U=121$, $p=0.018$), while 7 year-olds encode characters' goals less frequently than 12 year-olds ($U=123$, $p=0.028$). These results indicate that with increasing age the ability to understand and appropriately encode characters' actions as relevant to a goal plan is developing. Children, especially 7 and 9 year-olds, tend to present the relevant actions as temporally related to each other, rather than as attempts causally related to their goals (example 3). Since, as mentioned earlier, the degree to which the narrator can infer and apply in a consistent way a goal-attainment plan in a series of events affects the construction of coherent episodes, this finding reinforces the conclusions drawn from the examination of the first parameter of narrative structure (see section 3.1) that the ability to construct complete and coherent episodes is developing from 7 to 12 years of age. This ability is still developing after the age of 12, since only adults appear to systematically express and encode characters' actions as purposeful attempts.

Chart 2 Actions with or without a goal by age group

- (3) Μετά από λίγο γύρισε η μαμά τους με το φαγητό. Μόλις σκαρφάλωσε η γάτα στη φωλιά ο σκύλος την τράβηξε από την ουρά.
'After a while their mother came back with food. When the cat climbed to the nest the dog pulled him down' (7y)
- (4) Ο σκύλος την είδε και θέλησε να τη σταματήσει γι' αυτό που πήγαινε να κάνει.
'The dog saw him and wanted to stop him from what he was planning to do.' (12y)
- (5) Έλα όμως που στη γειτονιά ήταν κι ένας σκύλος. Στους σκύλους όπως όλοι ξέρουμε αρέσει να κυνηγούν τις γάτες.
'But a dog was in the neighborhood. As we all know, dogs like to chase cats.' (adult)

Moreover, qualitative analysis of the linguistic means used by the subjects to encode actions as attempts to attain a goal reveals that adults systematically express characters' goals implicitly, making references to their stereotypical properties (e.g. *the protective mother*, *the evil cat*, *the faithful/good/protective dog*, example 5). This characteristic appears only sporadically in the stories of the 12 year-olds, who tend to explicitly encode characters' goals (example 4) and is missing from the stories of the two younger age groups. This indicates that adults incorporate characters into a global cognitive schema (e.g. cats are always chasing birds, dogs are chasing cats), which contributes to the formation of a complete mental representation of the story and, consequently, to the construction of narrative structure.

3.3 Causal relations between episodes

The third research question addresses children's ability to understand, infer and appropriately encode the causal relations between the story episodes. This ability exceeds the episode level and applies to the level of the story macrostructure.

There are two cases of causal relations between the "cat story" episodes; the first episode, the episode of mother leaving the nest to bring food to her little birds, can be connected to the second episode, the episode of the cat's attack, with enablement relation, since mother's departure gives the cat the opportunity to attack. Moreover, the third episode, dog attacking the cat, is embedded to the second episode (cat's attack) and the two episodes can be connected with a cause-effect relation, since dog's attack prevents the fulfillment of the cat's plan.

The criteria used to identify the causal relations between episodes were specifically developed for the purposes of the present study (Table 2). This is because this parameter of narrative structure has not been widely studied, as most of the developmental studies focus on the encoding of causal relations at the interclausal level with causal conjunctions. On the basis of these criteria, causal relations were annotated in the stories of all age groups.

1st – 2nd episode (enablement)	2nd – 3rd episode (cause-effect)
a) lexical items (adjectives) indicating that after their mother's departure the little birds were left alone (e.g. <i>alone, unprotected, helpless</i> etc)	a) evaluative devices indicating the positive outcome for the birds of the dog's attack (e.g. <i>fortunately, saved, safe, relieved</i> etc)
b) lexical items (verbs) indicating that the cat is waiting for the mother to leave (e.g. <i>wait, stark</i> etc)	b) evaluative devices and lexical items (verbs) indicating the negative outcome for the cat of the dog's attack (e.g. <i>unfortunately, stopped (the cat), pushed/took away, prevent, force to come down</i>)
c) expressions indicating that the cat is taking advantage of mother's departure (e.g. <i>she finds the opportunity, she doesn't waste time, she wouldn't miss this opportunity</i> etc)	c) non factual <i>before</i> -clauses indicating that there is a causal connection between the two events, since the main clause event (dog's attack) prevents the <i>before</i> -clause event from happening (cat's attack) (e.g. <i>he pulled the cat down at the right moment, before he catches the little birds</i>)
d) lexical items (verbs) of cognition or perception indicating that the cat was aware that the mother was away (e.g. <i>knew, understood, observed, noticed</i> etc)	d) counterfactual conditional sentences (e.g. <i>if the dog hadn't appear, the birds wouldn't be alive anymore</i>)

Table 2 Criteria for identification of causal relations between the “cat story” episodes

The percentages of the presence and absence of causal relations between the “cat story” episodes are shown in Chart 4. Again, adults encode the causal relations more frequently than all children age groups (7y-adults: $U=32$, $p=0.000$, 9y-adults: $U=49.5$, $p=0.000$, 12y-adults: $U=74$, $p=0.000$), while 7 year-olds encode causal relations less frequently than the 12 year-olds ($U=116$, $p=0.014$). Thus, the examination of this parameter shows that the ability to express causal relations linking episodes together into a hierarchical narrative macrostructure is gradually developing between 7 and 12 years and is still developing after the age of 12.

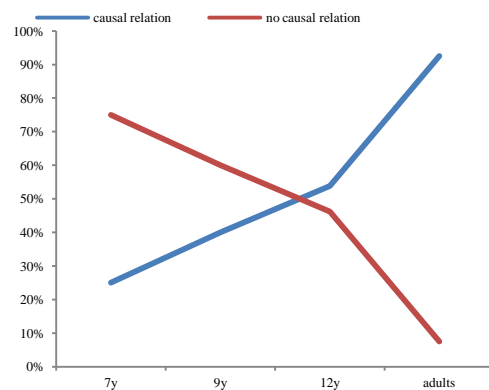

Chart 3 Presence and absence of causal relations by age group

More specifically, the examination of the two types of causal relations (Chart 5) shows that all children age groups encounter difficulties to infer and encode the enablement relation between the first (mother leaving the nest) and the second episode (cat attacking the nest) compared to adults (7y-ad: $U=60$, $p=0.000$, 9y-ad: $U=80$, $p=0.000$, 12y-ad: $U=90$, $p=0.000$). Moreover, 7 and 9 year-olds have difficulties in encoding the cause-effect relation between the second and the third episode. All children age groups tend to link the first and the second episode with temporal relation rather than with enablement relation (example 6), while the 12 year-olds show a more adult-like performance only regarding the connection between the second and third episode (examples 7-8).

Chart 4 Presence and absence of causal relations by type of relation

- (6) Αλλά μια γάτα που περνούσε από κει τα είδε και ήθελε να τα φάει και ανέβηκε στο δέντρο αλλά ένας σκύλος...
 ‘But a cat passing by saw them and wanted to eat them and she climbed up the tree but a dog...’ (7y)
- (7) και παραλίγο το κακό να γίνει. Αν δεν είχε εμφανιστεί ο σκύλος του σπιτιού τα πουλάκια δεν θα ζούσαν πια.
 ‘and things almost went wrong; if the dog had not showed up, the little birds wouldn’t be alive anymore’ (12y)
- (8) και τράβηξε την γατούλα από την ουρά την κατάλληλη στιγμή πριν αρπάξει η γατούλα τα πουλάκια.
 ‘And he pulled the cat from his tail just in time before the cat catches the little birds.’ (adult)

The difficulties of the 7 and 9 year-olds to encode the causal relation between the second and the third episode could be possibly attributed to their difficulty to control, in parallel, the local temporal relations between the events of the story and the global narrative macrostructure. The same seems to hold for encoding the enablement relation. However the enablement relation has an additional difficulty, even for the 12 year-olds. This relation is entirely the result of subjective interpretation of events, and is not supported visually by the “cat story” picture series. The two characters, mother and cat, do not come into any contact, and it is merely the absence of the former character which is causally associated with the presence of the latter. This favors the association of the two events with a temporal relation rather than a causal one.

4. Conclusions

The results of the study on the development of narrative structure in Greek-speaking children show that the ability to create global-level narrative discourse organization develops from 7 to 12 years, and the development continues even after the age of 12. Although children of all age groups demonstrate knowledge of the story schema, since they are able to produce stories which contain basic structural elements, it was observed that they favor linear event sequencing rather than causally relating the narrated events. This characteristic is more pronounced in the stories of the 7 and 9 year-olds. These two groups have more characteristics in common in most of the parameters examined, compared to the 12 year-olds. 12 year-olds seem to be in a transitional stage where they begin to attribute more consistently goals and motives to story characters and to encode causal relations between events and episodes. However, only adults demonstrate a fully developed ability to integrate events into a coherent mental representation of the story and encode them as causally related components of episodic structure and hierarchical macrostructure, producing stories of structural complexity and global-level organization.

The developmental trends found in the present study are consistent with previous research on narrative development, according to which development advances from the production of simple event sequences to the production of complete episodes (Peterson and McCabe 1983; Berman and Slobin 1994; Trabasso and Nickels 1992; Trabasso and Rodkin 1994; Shapiro and Hudson 1997), setting the age where narratives appear to approach adult-like performance at 12 years.

Children's observed tendency to favor local linear event sequencing rather than hierarchical causal connection between events, in comparison to adults, could be attributed to the cognitive effort required to control the different aspects of storytelling at the same time. Narrative production is a complex task which requires the coordination of several capacities, such as knowledge of the story schema, production of grammatical and meaningful sentences, processing and establishing interclausal - temporal and/or causal- relations, regulating information flow across utterances, causal inferencing and world knowledge. All these capacities activated in the process of narrative production draw on the same limited cognitive resources. In case of written story production, cognitive load is even more burdened by the process of handwriting, which is a particularly demanding task and is considered not to be fully automated even in secondary school-aged children (Christensen 2005). Thus, although research on each individual component of storytelling suggests that these skills are present in school-aged children, the results of the present study indicate that children, even at the age of 12, experience difficulties in putting all the "pieces" together in a complete whole, which affects their ability to construct hierarchical narrative macrostructure.

The results of the present study provide developmental evidence on the ability to construct narrative structure in Greek, which could serve as descriptors of narrative discourse production in Greek L1, with applicability to studies on Greek L2 acquisition or language impairments. Moreover, the linguistic criteria for defining the parameters of narrative structure in Greek could also be applied to studies in other research fields where narratives are being investigated, such as natural language processing.

ABSTRACT

Πολλά ουδέτερα ουσιαστικά σε -ι παρουσιάζουν ελλειπτικότητα στη γενική τόσο στον ενικό όσο και στον πληθυντικό, με γνωστότερη μεταξύ αυτών την περίπτωση των υποκοριστικών σε -άκι. Το παρόν άρθρο διερευνά την ελλειπτική κλίση των ουσιαστικών αυτών επισημαίνοντας ότι ομαδοποιούνται βάσει συγκεκριμένου χαρακτηριστικού, το οποίο και αποτελεί βάση για την προτεινόμενη ερμηνεία. Ταυτόχρονα, αξιολογούνται θεωρητικές απόψεις σχετικά με την εσωτερική δομή των κλιτικών παραδειγμάτων, τις διαφορετικές όψεις της έννοιας παραγωγικότητα (ως διαθεσιμότητας και πραγματωμένης παραγωγικότητας) και το ρόλο της γλωσσικής χρήσης και των ομιλητών.

Keywords: inflectional paradigm, defectiveness, gaps, productivity, Modern Greek neuter nouns, derivational

1. Introduction

Gaps in inflectional paradigms had been treated until recently as a peripheral phenomenon in language, of little consequence to linguistic theory (Albright 2003: 2, Karlsson 2000: 647, Baerman & Corbett 2010: 2). The revived theoretical interest in the notion of paradigm, on the one hand, and an increasing number of studies analyzing different types of paradigm gaps on the other have brought about proposals to integrate the relevant phenomena into the broader picture.¹ In several cases defectiveness may be related systematically to language structure (see among others Hansson 1999, Albright 2003, Rice 2005, 2007, Boyé & Hofherr 2010, Lucács, Rebrus & Törkenczy 2010, Stump 2010), while studying the role of language use and of speakers' strategies (Sims 2006, Daland, Sims & Pierrehumbert 2007, Löwenadler 2010, Mithun 2010) helped us to gain a better insight into the way(s) that such deficiencies emerge.

Baerman & Corbett (2010) distinguish between three main patterns of defectiveness: one affecting the forms of a paradigm, a second affecting the functions they realize and a third concerning the ways functions and forms are mapped to each other (Baerman & Corbett 2010: 4). According to these authors the defective genitive plurals in Modern Greek (henceforth: MGr) are an example of the diachronic 'decay of a paradigm', i.e. an example "where a morphosyntactic value is itself in the process of being downgraded so that latent problems in the paradigm of some lexemes may simply no longer be worth overcoming" (Baerman & Corbett 2010: 14). The genitive gap studied in the present paper does not concern just the plural, but also the singular, and affects specific groups of Modern Greek neuter nouns ending in -i. Furthermore, the missing forms do not involve hesitancy on the part of the speakers as regards the 'right' form of the genitive to be used, but rather unwillingness to use it. The paper is structured as follows: it starts with a reference to neuter diminutives derived by -άκι, which constitute the most known group affected by this gap, building on my previous treatment of this issue (Thomadaki 2008). Then explanations for this particular gap are reviewed, followed by a discussion of the notions paradigm structure and productivity with respect to the defective inflectional pattern under consideration. I will claim that the gap is related to the transparent derivational status of

¹ Compare statements such as the following: "Gaps are a reflex of grammatical competence. **Speakers have intuitions about them, and their competence allows them to identify situations in which a paradigm will be defective** for phonological reasons. It is therefore appropriate to include treatment of gaps in a model of grammatical knowledge" (Rice 2005: 170, emphasis E.Th.).

the nouns affected and will provide more data to support my view. Finally I will conclude with an overview of the main points illustrated linking them to the productivity issue.

2. MGr diminutives ending in –áki and the genitive gap

Diminutives carrying the suffix –áki appear to be a well-known case of defective MGr nouns. They also constitute the most productive pattern of diminutive derivation in Modern Greek (Babiniotis 1970: 214, Daltas 1985: 69-70, Mackridge 1985: 158, Stephany 1997: 149, Thomadaki & Stephany 2007: 117). In contrast to other diminutive suffixes such as –úla (FEM), –ítsa (FEM) (examples 1) or –úlis, –ákos, (both masculine, examples 2) requiring feminine or masculine bases respectively, no such constraint holds for the neuter suffix –áki (examples 3).

- | | | |
|------------------|--------------------|----------------------------------|
| (1) domata (FEM) | domat-úla | ‘small tomato’ |
| bala (FEM) | bal-ítsa | ‘small ball’ |
| (2) papus (MASC) | pap-úlis | ‘dear grandpa’ |
| anthropos (MASC) | anthrop-ákos | ‘poor little man’ |
| (3) domata (FEM) | domat-áki (NEUT) | ‘special kind of small tomatoes’ |
| anthropos (MASC) | anthrop-áki (NEUT) | ‘miserable little man’ |
| trapezi (NEUT) | trapez-áki (NEUT) | ‘small table’ |

Diminutives derived by the suffixes –áki, –úla and –ítsa miss their genitive plural forms. In addition, those suffixed by –áki also miss their singular genitive form as the examples in Table 1 (e.g. trapezaki ‘table:DIM’, domatúla ‘tomato:DIM’, balítsa ‘ball:DIM’) show.² The starred forms represent the possible realization of the missing forms in each case.

	Diminutives derived by –áki	Diminutives derived by –úla	Diminutives derived by –ítsa
NOM./ACC.SG	trapezáki	domatúla	balítsa
GEN.SG	*trapezakjú	domatúlas	balítsas
NOM./ACC.PL	trapezákja	domatúles	balítses
GEN.PL	*trapezakjón	*domatulón/*domatúlon	*balítsón/*balítson

Table 1 Defective diminutives

No gap is attested in the paradigm of diminutives formed by other suffixes such as –iðio (e.g. kratíðio ‘small state:NEUT’) or –úlis (e.g. paterúlis ‘dear father:MASC’) (Table 2).

	Diminutives derived by –iðio	Diminutives derived by –úlis
NOM.SG	kratíðio	paterúlis
GEN.SG	kratíðiu	paterúli
ACC.SG	kratíðio	paterúli
NOM.PL	kratíðia	paterúliðes
GEN.PL	kratíðion	paterúliðon
ACC.PL	kratíðia	paterúliðes

Table 2 Non defective diminutives

Furthermore, diminutives suffixed by –áki that have acquired an idiosyncratic meaning, such as suvláki ‘souvlaki’ (from suvla ‘spit’), sakáki ‘jacket’ (from sakos ‘sack’), plakáki ‘tile’ (from plaka ‘slab’), and loanwords, such as sokáki ‘backstreet’ (< Turkish sokak) are fully inflected (Table 3).³ In contrast, the reanalysis of the loanwords pasumáki ‘slipper’ (< Turkish pasmak) and tsarðáki ‘hut, home’ (< Turkish çardak) as diminutives suffixed by –áki has resulted to defective inflection (Table 3).

² The same defective pattern applies to neuter diminutive adjectives and nouns derived by –úli (e.g. mikrúli ‘small:NEUT’ (< mikró), perioðikúli ‘magazine:DIM’ (< perioðikó) and those derived by –éli (e.g. moruðéli < morúði ‘baby:DIM’ < moró ‘baby’).

³ Non-defective lexicalised diminutives carrying the suffix –áki (such as sakáki) should be distinguished from examples such as jeráki ‘hawk’, avláki ‘ditch’, vamváki ‘cotton’, mustáki ‘moustache’. The latter are lexicalised diminutives too, but they carry the suffix –i(on), similarly to other neuter nouns ending in –i (compare: 1. jeráki < ierák-ion < ierák-s ‘hawk’ and 2. molívi < molyv-ion < molubdos ‘lead’). They are, of course, not defective, similarly to non derived neuters such as skáki ‘chess’, spanáki ‘spinach’.

	non defective diminutive	Loanword ending in –áki	
		Reanalyzed as diminutive	no reanalysis
NOM./ACC.SG	suvláki	pasumáki	sokáki
GEN.SG	suvlakjú	*pasumakjú	sokakjú
NOM./ACC.PL	suvlákja	pasumákja	sokákja
GEN.PL	suvlakjón	*pasumakjón	sokakjón

Table 3 Comparing non defective lexicalised diminutive and loanwords

A lexicalized, and hence fully inflected, neuter diminutive (e.g. suvlaki) follows the pattern of neuter nouns ending in –i, exemplified by the noun molívi ‘pencil’ in Table 4.

NOM./ACC.SG	molívi
GEN.SG	molivjú
NOM./ACC.PL	molívja
GEN.PL	molivjón

Table 4 Inflection of neuter nouns ending in –i

Since the missing genitive forms of defective diminutives ending in –áki could be ‘recovered’ according to this pattern (see Table 1), it follows that diminutives ending in –áki exhibit potentially the same pattern too. Thus, they represent a subgroup within neuter nouns ending in –i.

The recoverability of the missing genitive form of a diminutive ending in –áki is demonstrated by occasional examples attested in texts of lower/ everyday style such as 4 and 5 (source: Corpus of Greek Texts (<http://sek.edu.gr/>), Goutsos 2010).

- (4) (a) Vunakjú ‘Vunaki:GEN.SG’
 (b) Monastirakjú ‘Monastiraki:GEN.SG’
 (5) (a) korðelakjón ‘ribbon:DIM:GEN.PL’⁴
 (b) γερανakjón ‘hoist:DIM:GEN.PL’⁵

Therefore, the gap results from speakers’ tendency to avoid the relevant genitive forms rather than from a genuine inability to form them. Grammar books referring to the defective inflection of these neuter nouns attempt to record this avoidance behavior.

Speakers use a number of strategies to compensate for the defective genitive under consideration. They may resort to either the genitive form of the base (i.e. non diminutive) noun (e.g. tu trapezjú ‘ART:GEN table:GEN’) or to a periphrastic expression (e.g. apo to trapezáki ‘of the table:DIM:ACC’). Further, a high-style genitive form (examples in 6) may typically be used in expressions containing place names ending in –áki.

- (6) Platia Kolonakíu ‘Kolonaki:GEN square’
 Nero Lutrakíu ‘Lutraki:GEN table water’
 Dimos Tibakíu/Muzakíu ‘municipality of Tibaki/ Muzaki:GEN’
 Stena Dervenakíon ‘Dervenakia:GEN pass’

The genitive forms in (6) conform to the inflectional pattern of neuter nouns ending in –o, exemplified in Table 5 by the noun klimákio ‘group (of a larger party)’.⁶

NOM. /ACC.SG	klimákio
GEN.SG	klimakíu
NOM. /ACC.PL	klimákia
GEN.PL	klimakíon

Table 5 Inflection of neuter nouns ending in –o

⁴ The form occurs in the text of a recipe: *Διπλώνομε την κρούστα [...]. Την κόβουμε σε σχήματα κορδελλακιών* ... ‘We fold the crust [...]. We cut ribbon-like strips.’ (source: CGT, translation E.Th.).

⁵ The form occurs in a magazine article: *Επίσης ο ΟΓΑ διέκοψε τη χορήγηση των ανυψωτικών συστημάτων, των γνωστών “γερανakiών”, πιθανώς επειδή δεν χρειάζεται τους ασφαλισμένους με τετραπληγία* ‘Also, OGA has suspended supplies of lifting machinery, the so called ‘geranakja’, to insured quadriplegic persons, probably because these persons are not needed’ (source: CGT, translation E.Th.).

⁶ It seems that the alternative genitive forms in (6) constitute an instance of heteroclisis (Stump 2006), an issue which will not be pursued further here.

In sum, the genitive gap under consideration has the following features:

- it affects systematically both genitive singular and plural
- it is possible to ‘recover’ the missing forms
- it affects consistently only transparent diminutives.

In order to understand why this is so, further groups of defective neuter nouns ending in –i shall be introduced in section 5 after referring to possible explanations for the genitive gap found in the relevant literature (section 3) followed by a discussion relating defectiveness to paradigm structure and productivity.

3. Possible explanations for the genitive gap

Since the gap is most prominent in diminutives ending in –áki, it was originally discussed with regard to the question whether defectiveness is directly tied to the semantic (or pragmatic) feature DIMINUTIVE (Triandafyllidis 1963, see also Thomadaki 2008). As suggested by Triandafyllidis (1963: 146, 149), the discourse functions of a diminutive, i.e. its usual syntactic slots, tend to ‘discourage’ the use of a genitive form, thereby contributing to the emergence of the gap. However, Triandafyllidis (1963: 150) finally dismisses this explanation arguing that some types of diminutives do occur in genitive forms (compare the examples: *tis varkúlas* ‘ART:GEN boat:DIM:GEN’, *tis yatítsas* ‘ART:GEN cat:DIM:GEN’ in Triandafyllidis (1963: 150), see also Tables 1 and 2 above). Instead, Triandafyllidis (1963: 150) opts for an explanation based on the diachronic pressure for elimination of synthetic case forms, which is reinforced by the tendency to preserve formal stability within inflectional noun paradigms on the dimensions of stem shape and of stress. Due to this tendency marginal forms such as *tu Rináki* ‘ART:GEN Rinaki’ emerge in certain contexts according to Triandafyllidis (1963: 154-156, 157-158),⁷ who consequently focuses on the formal means taking over the function of the avoided genitive rather than to the gap itself. Nevertheless, it remains unclear how the specific genitive gap under discussion could have resulted from the interaction of factors guiding the restructuring of MGr inflection in general. Moreover, the diachronic pressure leading to the elimination of synthetic case forms is too broad an explanation to account for the particular features of this gap.

As far as stress is concerned, it must be noted that both the singular and plural genitive forms of neuter nouns ending in –i bear obligatory stress on the last syllable, so that the genitive diverges from the stress pattern of the nominative/accusative. According to Drachmann & Malikouti-Drachmann (1999: 907) this pattern of stress shift represents an irregular (opaque) stress pattern, tending to leveling. However, the assumption that the gap is caused by the obligatory stress shift is far from convincing as long as it does not offer a substantiated answer to the question why only diminutives ending in –áki are targeted by the gap and not the entire class of nouns ending in –i (or other classes of nouns shifting their stress onto the last syllable in genitive).

More recently Sims (2006: 121) defined the role played by stress shift in the avoidance of genitive forms in MGr nouns not as a consequence of stress variation per se, but rather as an issue relating to the predictability of stress placement. According to her description, the implicational relations between the paradigm cells of MGr noun inflectional classes, extending on both the dimension of case formatives and of stress patterns, build a multidimensional inheritance hierarchy (Sims 2006: 102), which allows the identification of paradigm cells qualifying for a gap. She argues that an overwhelming 98% of the genitive plural gaps cluster with certain inflection classes of feminine and masculine nouns (e.g. *níki* ‘victory’, *óra* ‘hour’, *mitéra* ‘mother’, *turístas* ‘tourist’, *náftis* ‘sailor’, *patéras* ‘father’). The genitive plural of these nouns can be associated either with stress shift (obligatory stress on the last syllable) or with a (more or less) columnar stress pattern. For instance, in the genitive plural of the noun *petalúða* ‘butterfly’ there would be a choice between a form stressed on the ultimate syllable (*petalúðón*), parallel to the noun *óra* ‘hour’ (GEN.PL *orón*), and a form stressed on the penultimate (*petalúðon*), parallel to the noun *mitéra* ‘mother’ (GEN.PL *mitéron*). Through experiments testing the interaction between stress type and lemma frequency as well as subjects’ confidence about the production of the required genitive plural form, Sims shows that competing stress patterns do not directly activate the paradigmatic gap. Nevertheless, competing stress patterns in combination with low frequency create

⁷ The expression consists of a genitive article form followed by the NOM/ACC form of the neuter hypocoristic noun *Rináki* (derived by truncation and subsequent suffixation from the female name *Irini* ‘Irene’). The few examples of this aberrant construction cited by Triandafyllidis’ (1963: 151-2) are drawn mainly from dialects.

uncertainty about the form of the synthetic genitive plural, thus speakers tend to avoid it in favor of the periphrastic prepositional phrase (Sims 2006: 100).

However, Sims's account pertains to genitive plural gaps in feminine diminutives derived by the suffixes *-úla* or *-ítsa*, not to the gap in neuter diminutives ending in *-áki*.⁸ In fact she admits that it is unclear why a gap exists in this latter case (Sims 2006: 72, fn. 49), given that the genitive plural of nouns ending in *-i* (and by the same token that of diminutives ending in *-áki*) is always predictable from the genitive singular. Nevertheless, by employing the notion of paradigm structure as a necessary element for the explanation of MGr gaps (Sims 2006: 120), her analysis offers a plausible description of the interdependence between the genitive singular and plural in nouns ending in *-i*.⁹ Further, her analysis correctly integrates stress patterns into MGr paradigm structure, thereby relating the genitive plural gap she analyses not to stress shift but to competing stress patterns.

The claim that paradigms have internal structure and that inflectional forms stand in relation to each other, thereby following predictable patterns, offers a sound basis for the discussion of gaps.¹⁰ Gaps are detected by comparing a particular lexeme to other lexemes, all of which are expected to obey the same inflectional pattern. Contrary to the expectations created by the relevant paradigmatic pattern, defective items lack some form(s). Thus, reference to the notion of paradigm structure is necessary in order to understand and explain the gap discussed here.

Stating that diminutives ending in *-áki* lack their genitive forms means that we recognize that this particular subgroup fails to obey a valid inflectional pattern, which is realized by other nouns of the same group, e.g. by lexicalized diminutives ending in *-áki* (e.g. *sakáki*, *sokáki* etc.) and by nouns ending in *-i* (e.g. *kutí* 'box', *xéri* 'hand' etc.). Given that diminutives ending in *-áki* constitute a subset of the neuter nouns ending in *-i*, it follows that their potential genitive forms would look like the relevant inflectional forms of these nouns (e.g. *peđáki*: *peđakjú*: *peđakjón* parallel to *peđí*: *peđjú*: *peđjón*), in the same way that their nominative/accusative plural form (e.g. *peđákja*) parallels the relevant form of nouns ending in *-i* (e.g. *peđjá*). In addition, the strong interdependence between the genitive singular and genitive plural of these nouns, expressed mainly through the obligatory stress shift on the last syllable, could explain why the gap affects uniformly the genitive singular and genitive plural in the case of diminutives ending in *-áki*.

Diminutives derived by *-áki* are not really different from non-defective neuter nouns ending in *-i* as far as their paradigmatic pattern is concerned. Their genitive forms are not impossible on strictly semantic, phonological or morphological grounds, but rather unacceptable. Speakers avoid their use, thereby signaling some kind of information specific to the particular group.

In a previous attempt to consider the role of linguistic use, I focused on differences in the frequency of occurrence of each grammatical form in an inflectional paradigm (Thomadaki 2008: 134-137). It is well known that frequency of use may determine the 'lexical strength' of a form within a paradigm (Bybee 1985; 1991: 70, 78; 2001: 113-116), which may lead to a resistance to regularization. As far as the genitive gap under discussion is concerned I have claimed in Thomadaki (2008) that the overall low token frequency of genitive forms in corpora of MGr discourse and the high productivity of diminutives suffixed by *-áki* combine to cause the rejection of the genitive forms. The high productivity of the pattern deriving these diminutives sets them apart from other neuter nouns ending in *-i*. Speakers tend to 'interpret' the rare possibility of encountering genitive forms of a diminutive as a regular 'gap' for this clearly delimited group of nouns.

4. Productivity as profitability

Bauer (2001: 213) considers 'productivity' to be ambiguous between 'availability' and 'profitability'. While availability is "a yes/no matter", profitability is "a matter of degree" and it can be measured. That is possible words are not all equally probable, due to the complex interaction of the constraints imposed upon each type of formation in a particular language (Bauer 2001: 207). According to Bauer (2001: 209-210) "availability is a matter of what the language system determines; profitability is a matter which is determined by language norms". Bauer's distinction is easily and naturally interpreted, as far as derivation is concerned, it can, however, be usefully extended to inflection: in effect, any kind

⁸ Thus it is important to distinguish between the two cases, as Thomadaki (2008: 131) also noticed.

⁹ According to Sims (2006: 118), their interdependence can be formulated as an implicational relation from the gen.sg to the gen.pl. Adopting a different theoretical framework Thomadaki (1994) also maintained that these two paradigm cells are interdependent.

¹⁰ "Defectivity is intimately tied to the notion of inflectional paradigm" according to Karlsson (2000: 647).

of morphological process may be less than fully productive (see Jackendoff (1997: 121), cited in Bauer (2001: 17), Dressler (2003) on ‘grammatical productivity’).¹¹

The distinction between availability and profitability seems suitable for the description of the status of the missing genitive forms under consideration. Although genitive forms are available for every neuter noun ending in –i, i.e. they constitute possible (or potential) words, the profitability of the relevant inflectional pattern (its utilization in terms of actual use) is extremely low in the case of diminutives ending in –áki. Given that such a diminutive could be derived from almost every noun, the low profitability trend concerning their genitive forms becomes more robust with every new member of the group (Thomadaki 2008). In essence, the genitive gap in diminutives ending in –áki exists in terms of profitability, not of availability. Thus, the distinction between availability and profitability is compatible both with the avoidance of the genitive forms, as well as with their occasional attestation.

Diminutives suffixed by –áki constitute a productive derivational pattern and since the gap applies consistently to items being assigned derivationally to this pattern, one could conclude that speakers take into account the derivational status of a diminutive noun in –i in order to decide whether it lacks its genitive forms or not. If a lexeme loses its derivational status (i.e. no diminutive meaning is present), the (available) genitive forms become acceptable. Therefore, it is the assignment of derivational status as such that sets apart a diminutive from a non defective neuter ending in –i. Note that this assumption is compatible with the view that the diminutive meaning cannot explain the gap adequately.

Insofar as the ‘derivational status’ of –áki diminutives builds a kind of restriction rendering the relevant nouns incompatible with the full inflectional pattern, it reflects the way language use leads to generalizations about groups of lexical items concerning their inflection. In other words, inflectional patterns are obligatory and general, hence highly productive, but they do not apply blindly to the respective groups of inflected lexemes, because their profitability depends on the interaction of various factors. In the case of neuter nouns ending in –i profitability depends on ‘derivational status’.

5. The impact of derivation

The various groups of derived and simple neuter nouns ending in –i cannot be treated as a homogeneous class as far as inflection is concerned, for the reason that almost 2/3 of them do not display the fully fledged pattern exemplified by the noun *molívi* ‘pencil’ in Table 5.¹² The genitive gap under consideration affects compounds (examples 7a-e), backformations from verbs (example in 8) and derivations suffixed by –íði (9a) and –(il)íki (9b), besides the diminutives discussed so far.

(7) (a)	papaðopéði	*papaðopeðjú	*papaðopeðjón	‘a priest’s child’

(9) (a)	kanoníði	*kanoniðjú	*kanoniðjón	‘cannon fire, shelling’
(b)	proeðrilíki	*proeðrilikjú	*proeðrilikjón	‘presidency (derog.)’

¹¹ Using the term ‘grammatical productivity’ Dressler (2003) “posit[s] the notion of productivity on the level of the potential system of grammar” (Dressler 2003: 34), and acknowledges degrees of productivity for inflection (Dressler 2003: 44).

¹² It is indicative of the diversification within the class that out of the approximately 2650 neuter nouns ending in –i listed in Kourmoulis’ Reverse Dictionary (1967/2002) ca. 800 are fully inflected.

Although nouns such as these exemplified above, resulting from derivational or compounding processes, are formally parallel to simple neuter nouns carrying the final *-i* such *peði* ‘child’ or *xéri* ‘hand’ they do not display the full inflectional pattern. Note that the genitive gap appears even if a non-defective simple noun appears as the right constituent of the compound (compare 7a, b and e with the fully inflected simple nouns *peði* ‘child’ (gen.sg: *peðjú/* gen.pl: *peðjón*), *kutí* ‘box’ *kutjú/kutjón*, *xartí* ‘paper’ *xartjú/xartjón*). This means that the respective constituents of the compound do not retain the inflectional properties of the simple nouns.¹³

In contrast to the examples quoted in (7) through (9), certain compounds or derivations with similar morphological structure are not defective (see examples 10 and 11). An explanation which comes to mind is that the latter compounds or derivations are lexicalized and have accordingly lost their semantic transparency. Thus *kalokéri* does not mean ‘good weather’, but rather ‘summer’, neither is *skupíði* ‘rubbish’ automatically related to *skúpa* ‘broom’ or *skupízo* ‘sweep’. Similarly a lexicalized diminutive such as *suvláki* is non-transparent and must be paraphrased as ‘meat prepared on a skewer’ rather than ‘small skewer’. Lexicalization, however, seems to be inadequate as an explanation for the fully inflected examples in (11a) and (11b). Neither the backformation *kiniyi* (11a, from the verb *kiniyó*), nor the derivation *armatolíki* (11b, from *armatolós* ‘armed Greek during the Ottoman era’) may be considered as more lexicalized than the backformations in (8) or the derivation in (9b). However, the fully inflected *kiniyi* can be traced back to an older form *kiniyion* (gen.sg. *kiniyíu*, gen.pl. *kiniyion*), rendered as *kiniyi*, *kiniyjú*, *kiniyjón* in Demotic or MGr, while the defective noun *kolibi* constitutes a more recent derivation. The same is true of *proedrili* (9b) as compared to *armatolíki* (11b).

(10)(a)	<i>kalo-kéri</i> good-weather	<i>kalokerjú</i>	<i>kalokerjón</i>	‘summer’
(b)	<i>mesi-méri</i> middle-day	<i>mesimerjú,</i>	<i>mesimerjón</i>	‘noon’
(c)	<i>pano-fóri</i> over-wear	<i>panoforjú</i>	<i>panoforjón</i>	‘overcoat’
(11)(a)	<i>kiniyi</i>	<i>kiniyjú</i>	<i>kiniyjón</i>	‘hunting’
(b)	<i>armatolíki</i>	<i>armatolíkjú</i>	<i>armatolíkjón</i>	‘region controlled by <i>armatolós</i> ’
(c)	<i>skupíði</i>	<i>skupiðjú</i>	<i>skupiðjón</i>	‘rubbish, trash’

From the data presented thus far it follows that the genitive gap affects not only diminutives but also other types of derived or compound neuter nouns ending in *-i*, while simple (i.e. non derived) nouns ending in *-i* display the fully-fledged pattern. Also, lexicalization or frequency of use results in activating the full inflectional pattern in the case of a derived or compound lexical item. In other words, derivational transparency seems to trigger the genitive gap. Since transparency is a matter of degree (i.e. it reflects linguistic use), the more transparent the derivational character of a neuter noun ending in *-i* is, the more likely it is to be affected by the gap. This view allows a more realistic and usage-orientated insight as to how the genitive gap under consideration works. At the same time it does not contradict the view that the fully-fledged inflectional pattern is available for all neuter nouns ending in *-i*.

Furthermore, the inflectional forms of diminutives, compounds and other derived neuter nouns in *-i* (e.g. forms such as *peðaki* ‘small child:SING’ – *peðakja* ‘small child:PL’) appear to realize just an opposition of singular vs. plural.¹⁴ Nevertheless, they can be assigned case properties too (i.e. *peðaki* ‘small child:NOM/ACC.SING’ – *peðakja* ‘small child:NOM.ACC.PL’) through their association to the fully-fledged inflectional pattern valid for the wider class of neuter nouns in *-i*.

The availability of this fully-fledged inflectional pattern also manifests itself in the way that loanwords of Turkish origin become morphologically assimilated into MGr inflection. While the nouns in (12) are incompletely integrated into the pattern of neuter nouns ending in *-i*, only exhibiting a number distinction, those in (13) have also developed genitive forms.

¹³ It is preferable to analyze the final *-i* as a formal marker of the compound stem than as part of the second compound constituent (as Ralli 2007: 177 proposes). The former analysis relates the presence the final *-i* more directly to the inflectional pattern of the noun.

¹⁴ See Thomadaki & Stephany 2007 on child language data concerning this issue.

- (12)(a) áti – átja - *atjú - *atjón ‘horse’
 (b) zóri – zórja – *zorjú - *zorjón ‘difficulty’
 (13)(a) γléndi- γlendjú- γléndja – γlendjón ‘fun, feast’
 (b) réli- reljú – rélja – reljón ‘hem’

Of course, in the case of loanwords, it is meaningless to speak of a ‘defective’ inflectional pattern, since loanwords fall by default outside the inflectional system of the recipient language, in contrast to native lexical items, and their integration into this system proceeds analogically and item-wise. But as in the case of defective neuter nouns discussed here, the profitability of the available inflectional pattern is dependent upon linguistic use.

6. Summarizing – Further questions

The genitive gap affecting groups of neuter nouns ending in –i (diminutives, derivations, compounds) discussed in this article revealed some important aspects related to inflectional defectiveness:

- The gap affects in tandem genitive singular and plural, so it is different from other instances of genitive gap referred to for MGr. The relatedness between the singular and the plural genitive form claimed to be an intrinsic feature of the inflectional pattern of neuter nouns ending in –i (Sims 2006) helps to explain why this cannot be a coincidence.
- The gap results from a strong preference on the part of the speakers to avoid the genitive forms rather than of the speakers’ genuine inability to form them, since such forms are occasionally attested. The gap affects subgroups of nouns within a wider non defective inflectional class.
- It has been argued that the speakers’ avoidance of genitive forms depends on whether the relevant neuter nouns ending in –i have a transparently derivational status or not. Lexicalized nouns of the subgroups do not show any gap.
- The latter testifies to the availability of the fully-fledged inflectional paradigm, realized by non defective neuter nouns ending in –i, and furthermore it points to the speakers’ ability to relate defective subgroups to this pattern.
- The fact that the genitive gap heavily depends on usage and the profitability of the inflectional paradigm is limited as far as genitive forms are concerned show that inflectional patterns are not a priori ‘productive’, but constitute a matrix into which nouns may possibly fit.

A question arising from the discussion above is the following. Why should exclusively neuter nouns in –i become affected by this specific type of defectiveness, which depends, as argued above, on whether a respective noun has a transparently ‘derivational status’ or not? An answer to this question may require a closer look at the structure of inflectional paradigms of MGr nouns in general, taking also into account the use of alternative genitive forms such as tu Kolonakiú (see examples 6 above), which possibly involve heteroclisis. Moreover, the proposed explanation raises questions about the lexical storage of inflected words, since speakers are able to discern which neuter nouns in –i are defective and which are not.

*I thank the audience of the 10th ICGL whose remarks have contributed to the improvement of the original version. All remaining shortcomings are of course my own responsibility.

ACRONYMS AND THE PLACEMENT OF DEFAULT STRESS IN GREEK

Nina Topintzi

ABSTRACT

This paper aims to identify the stress pattern of Greek acronyms experimentally and to provide insights over default stress, in light of work suggesting that this arises in morphologically-bare forms (Krämer 2009), such as acronyms. Two experiments with novel acronyms were conducted. The first tested stress preferences; the second attempted to understand those by deliberately priming speakers to attend to morphology through the use of suffix-like endings in acronyms. A clear preference for final stress was evident throughout; in acronyms with suffix-like endings, this is attributed to a combination of morphology and lexical frequency effects of the least frequent words. In acronyms ending in non-native codas - thus free of such influences - this is due to default stress placement, a finding that challenges previous work on Greek default stress.

1. Introduction and Aims

The study of nonce words, and acronyms in particular, has gained momentum in recent years, as a source able to reveal the underlying linguistic knowledge that speakers have when they are confronted with new data of their language. Following this trend in Greek acronyms, we find a general survey of acronyms by Vazou & Xydopoulos (2007) who briefly touch upon their phonological properties, with further elaboration by Nikolou (2010) on the number of phonological words acronyms consist of and by Malikouti-Drachman & Drachman (2011) on factors that may affect their stressing. In this paper, we explore acronym-stress too, but focus on production and stress patterns as revealed by quantitative data. To our knowledge, this is the first work to do that, along with the independently conducted work by Nikolou, Papadopoulou and Revithiadou (2011), that was also presented at ICGL 10 and can be found in this volume.

The present investigation aspires, first, to identify the stress pattern(s) characteristic of Greek acronyms. To this end, we constructed two experiments investigating various phonological, morphosyntactic, morphological and lexical frequency factors that can potentially regulate the attested stress distribution. Our second aim is a consequence of the first; as it will become obvious in the course of this paper, we establish that the default pattern for acronyms (final stress) does not coincide with that generally claimed for the language (see below) and we therefore briefly discuss the consequences of this result.

Our main finding is that the preferred pattern in acronyms is ultimate stress. This is especially the case in C-final acronyms that end in non-native codas, e.g. p, v, θ, etc. However, when the acronym ends in a string of sounds like -os or -i that can be construed as suffixes, speakers may divert from the default¹; in that case, the emerging stress distribution matches the frequency patterns of the *least* frequent words. It is thus the combined effect of morphology and lexical frequency that becomes relevant in acronyms. In addition, the preference for final stress comes at odds with claims that the antepenult is the default (Revithiadou 1999) or the more recent proposal that the penult is instead the default (Malikouti-Drachman 2001, Kappa 2002, Protopapas et al. 2006). On the contrary, it is compatible with work by Apoussidou (on virtual learners and her finding (2011: 125) that “neither

¹ We take it that final stress is at the very least the default pattern in acronyms. On the *general* default pattern in Greek, see section 4.

stress on the antepenult... nor the penultimate syllable... were the default pattern for untrained forms; rather, the final syllable was a preferred position”.

The paper is structured as follows: Sections 2 and 3 describe the first and second experiments respectively and outline their major findings. Section 4 briefly considers issues stemming out from the findings regarding the final default stress in acronyms.

2. 1st Experiment (Exp.1)

2.1 Methodology

Our 1st experiment involved a written task whose aim was to identify whether there was any clear pattern in acronym stressing. 17 subjects – first year undergraduate students of Linguistics at the University of Ioannina – were tested, but eventually 2 were excluded, as their responses indicated a lack of understanding of the instructions. The choice of subjects was driven by their ability to use IPA for phonemic transcription, which was integral for the experiment’s purposes. The experiment consisted of two sub-tasks, henceforth referred to as 1A and 1B.

For 1A, the full names of 32 novel organizations were provided and subjects were asked to create corresponding acronyms. No restrictions were posed with regard to their structure (number of syllables, segmental material). Subjects were required to phonemically transcribe the acronym in IPA and to indicate stress and syllable structure. For example, for the organization *Κεντρική Επιτροπή Γενικών Εξετάσεων* “Central Committee of General Examinations” subjects produced either the acronym [cé.ðe] or [ce.ðé]. This subtask produced 480 tokens in total, i.e. 32x15.

The task in 1B was more controlled; subjects were presented with 38 novel organization titles alongside with their ready-made acronyms and were asked to provide syllabification and stress assignment [total 38x15 = 570 tokens]. Thus, for the acronym ΤΥΔΑΛ which stood for *Τεχνική Υπηρεσία Δήμου Άνω Λιοσίων* “Technical Service of Ano Liosia Municipality”, subjects – almost uniformly - offered [ti.ðál]. For examples of acronyms in each task, see Appendix A.

2.2 Results

2.2.1 Task 1A

Three basic questions were asked: (a) How long were the acronyms in terms of number of syllables? (b) Where was stress located? (c) What was the break down of stress position by the number of syllables? Figures 1-3 present the results to the respective questions.

Figure 1 (L) Acronyms by number of syllables (Task 1A)

Figure 2 (R) Position of stress in acronyms [1=ultima, 2=penult, 3=antepenult] (Task 1A)

Fig.1. shows that the preferred length of acronyms is disyllabic, followed by trisyllabic constructions. Few quadri- and mono-syllabic acronyms arise too. Fig.2. reveals that most acronyms are stressed on the ultima, a significant number is stressed on the penult, whereas stress on the antepenult is a rarity. Fig.3. provides a detailed break-down of how frequently each stress pattern appears on acronyms ranging between 2-4 syllables. In disyllabic acronyms, final and penult stress occur with roughly the same frequency. In trisyllables however, ultimate stress is predominant, with some occurrences of penult and antepenult stress. Surprisingly, in quadrisyllables, only one type of stress emerges, namely, the final one.

Figure 3 Break-down according to length of acronym and stress pattern (Task 1A)

2.2.2 Task 1B

The same questions were asked in Task 1B. The answers follow in Figures 4-6.

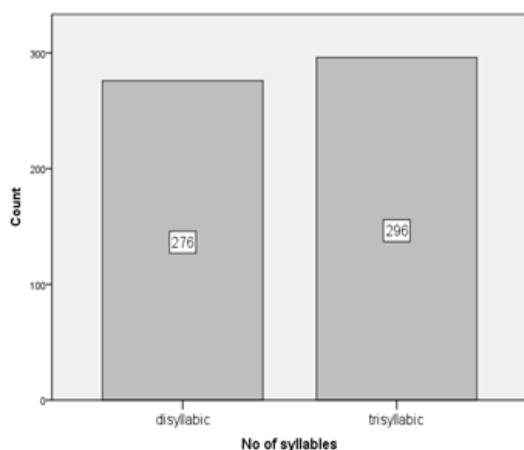

Figure 4 (L) Acronyms by number of syllables (Task 1B)

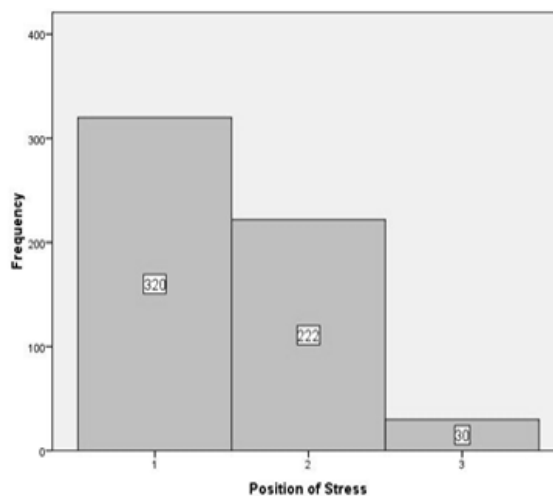

Figure 5 (R) Position of stress in acronyms [1=ultima, 2=penult, 3=antepenult] (Task 1B)

Since the length of the acronyms was pre-determined given the experiment's design, Fig.4. is not particularly informative, but is nonetheless included for clarity. Fig.5. replicates the results of Task 1A for that question. The same roughly holds for Fig.6.

Figure 6 Break-down according to length of acronym and stress pattern (Task 1B)

2.2.3 An asymmetry

The results of both sub-tasks of Experiment 1 are comparable: final stress tends to be preferred in acronyms larger than 2 syllables long, but in disyllables no preference appears. Importantly, antepenult stress, i.e. the alleged default according to Revithiadou (1999) is hardly ever attested. Also, task 1A shows that the preferred size of acronyms is disyllabic (monosyllabic: 3%, disyllabic: 65%, trisyllabic: 26%, tetrasyllabic: 6%).

An interesting asymmetry crops up when one looks the internal structure of disyllables and trisyllables with respect to stress. Thus, although it is true that disyllables receive either final or penult stress in roughly equal proportion, there is for the most part preference for final stress if the acronym ends in a closed syllable and a slight tendency for penult stress if it ends in an open syllable (see Table 1). This is not true for trisyllables though, where no matter the internal structure of the acronym, final-stress is consistently preferred (Table 2). To facilitate comparison, consider the cells in bold in the figures below.

	ultima	penult
CV.CV	50	63
CV.CVC	45	9
V.CV	9	20
V.CVC	12	2
VC.CV	7	3
CV.V	3	11
CV.CCV	2	9
CCV.VC	1	5
CCV.CV	2	9

Table 1 (L) Break-down according to stress pattern and syllable structure in disyllables

	ultima	penult	antepenult
CV.CV.CV	22	1	5
V.V.CV	13	2	0
CV.CV.V	12	8	7
V.CV.CVC	9	2	0
CV.CV.CVC	8	0	0
CV.CV.VC	6	1	0

Table 2 (R) Break-down according to stress pattern and syllable structure in trisyllables

To explain this asymmetry we first considered the possibility that other factors could influence stress placement. For instance, Malikouti-Drachman & Drachman (2011) have claimed that the reason an acronym like [ika] for *Ιδρυμα Κοινωνικών Ασφαλίσεων* "Social Security Foundation" receives

penult stress is because of a preference to stress the morphosyntactic head, here *Τόρυμα*. In addition to this possibility, we also entertained the idea that acronym-stressing is sonority-driven (cf. Kenstowicz 1994 on Mordwin, Kobon, Chukchee), in that stress looks for the most sonorous vowel in the word to dock on, following the standard sonority scale of *a>e,o>i,u*. The relevant measurements appear in Appendix B, but the upshot is that none of these factors proved important in our data.

In conclusion, results from the first experiment revealed a preference for stressing the ultima in acronyms, with an asymmetry between disyllabic and trisyllabic acronyms in that in disyllabic acronyms closed syllables tended to attract the stress, with the reverse pattern emerging for the trisyllabic ones. Factors such as morphosyntactic head and vowel sonority did not prove significant in stress placement, nor in explaining the asymmetry indicated (but see Appendix B for details). However, other factors, such as the morphology of the constructed acronyms, were not taken into consideration, and it is to that which we turn to in the second experiment.

3. 2nd Experiment (Exp.2)

Since morphosyntactic head or sonority considerations offered no further insight to the asymmetry outlined above, we conducted an additional experiment, this time testing whether lexical frequency and/or morphological factors could regulate acronym/nonce word formation. This line of thinking is inspired by recent work by e.g. Guy et al (2008), Zuraw (2007) and many others who have shown that “speakers have encoded frequency information within a variety of static phonotactic constituents as well as within the targets, results, and contexts of phonological and morpho-phonological processes. In other words... speakers have statistical knowledge of language sound structure at a variety of levels” (Frisch 2011: 2144).

3.1 Methodology

Although acronyms themselves lack morphological substance (Vazou & Xydopoulos 2007: 247), we deliberately created acronyms whose endings could be construed as extant suffixes, e.g. *-os*, *-i*. We did that so as to be able to evaluate the role of any morphological or lexical frequency conditioning. Our hypothesis has been that speakers’ preferences regarding stress placement in acronyms might mirror what we find in attested words with respect to either: (I) morphology alone, (II) lexical frequency alone, or (III) both.

To test the hypothesis, we designed a more controlled experiment that only utilized disyllabic acronyms of the type CV.CV or CV.CVC. Specifically, we constructed 10 novel acronyms for each of the following categories (see Table 3) with specific endings and genders [10 speakers * 6 categories * 10 acronyms * 2 repetitions = 1200 items plus 200 trisyllabic filler acronyms]. These were read out loud by one of the authors, recorded and played back to the participants using PRAAT’s adjusted MFC5 perception experiment. Participants would first hear the whole organisation’s title which was also presented in a written form on the screen, and then hear the acronym twice, e.g. the choice over *Πλατφόρμα Ολικής Μηχανοργάνωσης* was between *ΤΙΟΜΗ* or *ΠΟ’ΜΗ* (forced-choice task, all participants would hear each acronym twice, once with the stress on the ultimate presented first, and once with the penultimate presented first, and the selection of which set came first or second was random). The participants were then asked to choose the preferred acronym².

Orthographic ending	IPA	Gender	as in the word...
a. -ου	-u	Feminine	[alepú] ‘fox’
b. -η	-i	Feminine	[fisi] ‘nature’
c. -ι	-i	Neuter	[póði] ‘foot’
d. -ος	-os	Masculine	[filos] ‘friend’
e. -ες	-es	Masculine	[pansés] ‘pansy’
f. non-native coda	e.g. Vf#, Vk#	Gender irrelevant	

Table 3 Categories of novel acronyms

²We did not opt for the participants to produce the acronyms themselves and for us to record them, because we wanted to avoid 2 issues: 1. the interference of our transcription as to which syllable is stressed (which would also require tests of inter-transcriber agreement), and 2. the possibility of uncertainties in the productions of the speakers themselves.

We also ensured that both the head of the phrase of the acronym as well as of its complement were of the gender sought after. For instance, ΠΙΟΜΗ could be an acronym for: Πλατόρμα_{Fem} Ολικής Μηχανοργάνωσης_{Fem}, where both head and complement primed for Feminine gender, but not for Πλάνο_{Neut} Ολικής Μηχανοργάνωσης_{Fem}, Πλατόρμα_{Fem} Ολικού Μηχανισμού_{Masc} or Πλάνο_{Neut} Ολικού Μηχανισμού_{Masc}, where at least the head or the complement are of different gender than the one sought after. Our aim was to prime for a specific stress pattern, through specific morphology.

To be able to evaluate possible effects of lexical frequency, we counted the lexical frequency of attested words with the above characteristics (ending, gender, σ-structure and number of syllables) in the corpus of: <http://speech.ilsp.gr/iplr/downloads.htm> (Protopapas et al. in press).

3.2 Results

Our initial analyses focused on the same questions, as in Tasks A and B of Experiment 1, to ensure that results were replicated in this experiment too. As the figures below reveal, the initial results indeed resemble those of Experiment 1.

Figure 7 (L) Break-down of stress position in all items

Figure 8 (R) Break-down of stress-preference placement by speaker [N.B.:mixed refers to an equal preference for stressing both syllables]

Evidently, ultimate stress is preferred (Fig.7.), a preference that is clear for 5 of the speakers (Fig.8.; 50%). 4 others provided mixed responses (no clear tendency for stress placement was found in those speakers; rather they tended to stress equally on both syllables) and only one showed a systematic preference for penult stress.

We then proceeded to answer the following questions posed by our hypothesis that are taken up in the next subsections.

- Q1: Does morphology alone regulate the stress pattern in acronyms?
- Q2: Does lexical frequency alone regulate the stress pattern in acronyms?
- Q3: Is the combined effect of morphology and lexical frequency that regulates the stress patterns in acronyms?

3.2.1 Does morphology alone count?

To determine the role of morphology in acronym stressing, we effectively asked whether any of the suffixes *-ος*, *-η*, *-ι*, *-ες* or *-οι*, are associated with any specific stress pattern independently of frequency and phonology (e.g. syllable structure, word-size, etc.). This question could only be answered for the suffixes *-ού* (Fem.) and *-ές* (Masc), as these are always reported to receive final stress (cf. the grammar of Holton et al. 2004: 35, 40-41). In the remaining suffixes, stress is variable, so not much else can be said on a morphological basis only.

Still, it is the case that if the morphological pattern alone were to be mirrored in the acronym, then all of the *-ες* and *-οι* final acronyms should be stressed in the ultima, which is clearly not the case,

since stress in *-ov* acronyms is pretty random (ultima 51%, penult 49%), whereas *-ες* acronyms do show a preference for final stress, but this is by no means as strong as predicted (ultima 63%, penult 37%). For concreteness, the overall picture with respect to the position of stress for each of the endings tested is presented in Fig.9., where we can also see a clear preference for stressing the ultima in non-native codas.

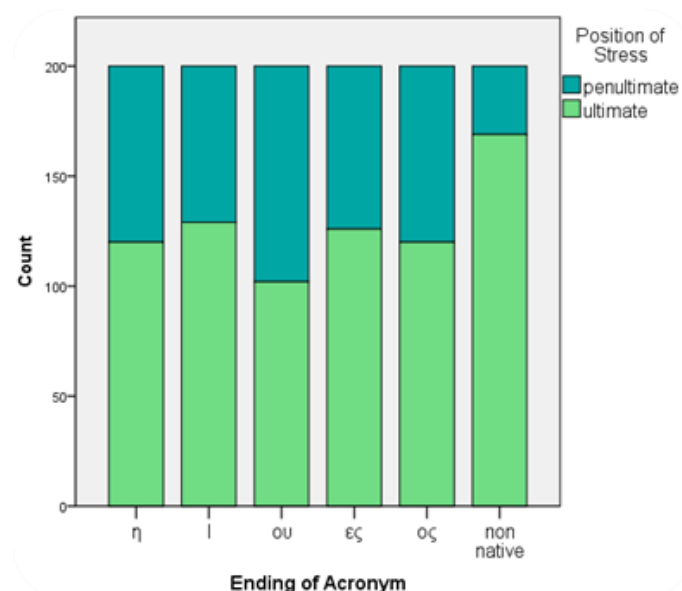

Figure 9 Break-down of stress position by ending

Overall, Fig.9. reinforces the impression of a final stress preference for disyllabic acronyms in Greek. Moreover, it shows that acronyms of CV.CVC syllabic structure have the same general distribution as those of CV.CV, with the exception of CV.CVC constructions that have a non-native coda. The latter clearly attract the stress on the ultima.

It can thus be concluded that morphology alone does not seem to predict position of stress. According to our morphology-based hypothesis, acronyms ending in *-ov* and *-ες* should be stressed on the ultima, a pattern that was not borne out.

3.2.2 Does lexical frequency alone count?

To decide on the influence of lexical frequency, we counted the frequency of all words ending in *-ος*, *-ες*, etc. irrespective of morphological information, thus along the target masculine nouns ending in *-ες*, we also included other *-ες* forms like *εἶδες* ‘you saw-2SG-PAST’, *λαβές* ‘handle-FEM-PL’ etc. The results attained were limited in some respects due to the structure of the corpus; in particular, the corpus really only provides comparison between syllables stressed in the final position and syllables in all other positions, that is, while the corpus indicates whether the stressed syllable is found in the *initial*, *medial* or *final* position, one does not know the length of each word where the syllable has appeared. Therefore, the only legitimate comparison we can presently perform is that of the frequency of occurrence of a stressed syllable in the final position vs. the frequency in all other positions, omitting finer comparisons between the penult and antepenult. In addition, since the corpus offers phonetic and not orthographic transcriptions for this analysis, a distinction between the homophonous *-ι* and *-η* could not be made. With these caveats in mind, consider the relevant results.

Frequency of syllable being stressed in final position vs. not being stressed (in whole corpus in millions)			Expectation for ultima	Results		Met?
	<i>Stressed</i>	<i>Not stressed</i>		<i>Ultima</i>	<i>Penult</i>	
/i/	118.457.881	161.871.572	Not stressed	64,5%	35,5%	Not met

/i/	118.457.881	161.871.572	Not stressed	60%	40%	Not met
/os/	58.555.149	75.682.644	Not stressed	60%	40%	Not met
/u/	69.169.946	141.436.418	Not stressed	51%	49%	Not met
/es/	65.051.777	67.689.173	No preference	63%	37%	Not met

Table 4 (Non-)matching of frequency of endings in corpus with those in acronyms

The sub-columns under the heading 'Frequency...' indicate the frequency of final and non-final stress in the corpus. This creates an *Expectation* on what the pattern should be in acronyms if these follow the corpus tendencies. The column *Results* depicts what actually happens in the acronyms tested. The final column *Met?* designates whether the *Expectation* has been met or not in acronyms.

As said, the frequency of *-i* final words in the corpus merges together all types of orthographic *i*'s (5 in Greek in total) including *-ι* and *-η*. The preference for stress here is non-final, as is for words ending in *-ος*, and *-ου* while for *-ες* no preference emerges from the corpus. Consequently, none of the expectations on the basis of overall frequency in the corpus are met, since a tendency for final stress is still observed. This suggests that lexical frequency alone is also not sufficient to generate the attested patterns.

3.2.3 Do morphology and lexical frequency combined count?

This leaves us with one more possibility: the combined effect of lexical frequency and morphological information. This time what we counted was the frequency of all CVCV(C) disyllabic words in the corpus that matched the morphological criteria, thus for the *-ος* ending, we considered only the *-ος* masculine nouns and not the masculine adjectives (e.g. *όμορφος* 'beautiful') or the feminine nouns (e.g. *μέθοδος* 'method') with the same ending. We then made three measurements for each of the endings utilized:

- Out of all the disyllabic CVCV(C) nouns in nominative that appear in the corpus, we counted how many were stressed in the ultima and how many in the penultima (frequencies are shown in percentages, Table 5)
- Out of all the disyllabic CVCV(C) nouns in nominative that appear in the corpus, we added the frequency (in this instance frequency refers to "frequency of occurrence of this word form (letter sequence) in the selected corpus, per million words (tokens)", Protopapas et al. 2008) of the 20 most frequent tokens in the ultima and of the 20 most frequent tokens in the penultima and compared which of the two syllables is most frequently stressed (Table 6)
- Same as before, but for the 20 least frequent tokens (Table 7)

	Frequency in corpus		Expectation	Results		Met?
	<i>Ultima</i>	<i>Penult</i>		<i>Ultima</i>	<i>Penult</i>	
<i>-ι</i>	43%	57%	Mixed	64,5%	35,5%	Not met
<i>-η</i>	39%	61%	Penultimate mostly	60%	40%	Not met
<i>-ος</i>	27%	73%	Penultimate	60%	40%	Not met
<i>-ου</i>	100%	0%	Ultimate (grammar descriptions)	51%	49%	Not met
<i>-ες</i>	100%	0%	Ultimate (grammar descriptions)	63%	37%	Met(?)

Table 5 Stress patterns of words with specific morphological endings in the corpus and their (non-)matching in acronyms

As is evident from Table 5 the expectations with regard to the stress patterns that should arise in acronyms based on the frequencies of the words in the corpus with the corresponding morphological endings are not borne out. The same holds when the expectations are based on the 20 most frequent words (Table 6). Note that the *-ου* and *-ες* categories should be uniformly finally stressed according to grammar descriptions. However, they were excluded, because insufficient number of them arose in the corpus.

	Frequency of 20 most frequent words		Expectation	Results		Met?
	<i>Ultima</i>	<i>Penult</i>		<i>Ultima</i>	<i>Penult</i>	
<i>-ι</i>	314,205	296,984	Mixed	64,5%	35,5%	Not met

-η	741,817	2892,163	Penultimate	60%	40%	Not met
-ος	116,148	833,775	Penultimate	60%	40%	Not met
-ου	-	-	Ultimate (grammar descriptions)	51%	49%	-
-ες	-	-	Ultimate (grammar descriptions)	63%	37%	-

Table 6 Stress patterns of 20 most frequent words with specific morphological endings in the corpus and their (non-)matching in acronyms

Interestingly however, the situation is reversed, once one looks at the stress patterns that are expected to emerge in acronyms based on the least frequent words. Here, the expectations largely match the actual results.

Frequency of 20 least frequent words			Expectation	Results		Met?
	<i>Ultima</i>	<i>Penult</i>		<i>Ultima</i>	<i>Penult</i>	
-ι	3,823	2,604	Slightly Ultimate	64,5%	35,5%	Met(?)
-η	12,111	5,107	Ultimate	60%	40%	Met(?)
-ος	3,281	1,152	Slightly Ultimate	60%	40%	Met
-ου	-	-	Ultimate (grammar descriptions)	51%	49%	-
-ες	-	-	Ultimate (grammar descriptions)	63%	37%	-

Table 7 Stress patterns of 20 least frequent words with specific morphological endings in the corpus and their (non-)matching in acronyms

Thus far we have not commented on the fact that participants' responses revealed a mixed pattern for the ending *-ου*, contrary to our expectations on the basis of the morphology, and contrary to its quite similar ending *-ες*. Once again, but on a more speculative note, we believe that key to this lack of preference is the combinatorial effect of morphology and overall lexical frequency. It is notable that on the basis of traditional grammars, *-ου* words should be stressed on the ultima (cf. §3.2.1), but on the basis of overall lexical frequencies we expect non-final stress – and indeed by a large margin (cf. Table 4, where non-finally stressed *-u* ending tokens are twice as many as the final-stressed ones). Starkly competing expectations are thus generated, which speakers seem to balance out by showing no particular stress preference in acronyms. To put it differently, this emerging mixed pattern has masked potential effects from morphology or from overall frequency. This line of thinking can extend to *-ες*, where on the basis of morphology we expect final stress and on the basis of overall lexical frequency we expect no preference. Our results reveal a 63% preference for the ultima, i.e. approximately in the middle between the two tendencies³. Of course, the reasoning above cannot apply to the *-ι*, *-η* and *-ος* endings, simply because morphology imposes no clear stress preference for them, hence morphology and lexical frequency cannot directly conflict with one another.

3.3 Summary

The overall picture of Exp.2. is comparable to that of Exp.1., in that there is a strong tendency for final stress. Notably, in acronyms with non-native codas (which of course are not subject to morphological or lexical frequency effects), stress is virtually always final. Of all the measurements we made, it was the combination of morphological and lexical frequency effects that matched to an extent the empirical facts of acronyms. Unlike what one would possibly expect, it was actually the stress patterns of the *least* frequent words that matched the stress patterns of the acronyms.

This effect is not as surprising, as it appears at a first glance. A similar result is reported in Crowhurst et al. (2003: 159) who find that the frequency distribution of stem-final stress in Russian is skewed, being more frequent for low-frequency lexical items than high-frequency ones. Given the fact that frequent words often present irregular patterns (cf. past forms in *go-went* or *βλέπω-είδα*), one could

³How stress patterns are affected when morphology and overall lexical frequency preferences compete has not been the topic of the present investigation and thus will require further testing. From the present results however, it seems that speakers' preferences lie in the middle of the two extremes, but not with complete precision, since in that case *-ες* should have a 75% preference for ultimate stress, and not 63%, unlike *-ου* which was split exactly in half.

perhaps argue that regularity should after all be sought after in infrequent words. The last section briefly outlines the implications the stressing of acronyms has for default stress.

4. Discussion

One thing that is clear from the experiments above is that the default stress pattern for acronyms is not the antepenult or even the penult, i.e. patterns that have been claimed to arise as defaults in the core language (Revithiadou 1999, Malikouti-Drachman 2001, Kappa 2002, Protopapas et al. 2006). Instead, a final, possibly iambic, stress pattern is assigned this role (see also Tzakosta 2004, who shows that trochees are attested with less frequency than anticipated in Greek child speech). We have also shown that this pattern is quite systematic in acronyms ending in non-native codas, where neither lexical frequency nor morphological information effects are in order, whereas in acronyms ending in sequences reminiscent of suffixes of the language, stress distribution is largely regulated by the combined effect of these two factors. Speakers may thus divert from the default under the pressure of the factors above.

What does all this mean for Greek default stress in general? The answer seems to depend on how one chooses to interpret the results; if one adopts the reasoning of researchers like Krämer (2009: 9 in ms) who states that “...since nonce words cannot have lexically stored stress marks we can claim that an analysis of the observed nonce word stress patterns amounts to an analysis of Italian default stress”, then the nonce acronyms of Greek that are free of morphological or lexical frequency effects may be used as an argument in favour of final stress as a default in Greek. On the other hand, proponents of the (ante-)penult default stress in Greek, as suggested by noun-inflection or compounding, may claim that what we see in acronyms is specific to them, in the sense that they have their own sub-phonology and as a result cannot extend to the general language. The problem however is that one could equally claim the reverse, i.e. that the real default arises in acronyms – when stripped of any other factors that may influence their stressing – and what we see in the morphologically-rich constructions of nominal inflection and compounding actually constitutes a sub-phonology⁴.

While it is not clear at present how this debate can be resolved, it certainly points to the need for additional research on Greek stress. Till then, the only thing that can be said with certainty – given the comparable results of Nikolou, Papadopoulou and Revithiadou (2011) – is that the final syllable is a favourite location for acronym stress.

⁴ Exp.2. has shown that, when morphological information is added to the acronyms, stressing preferences change with somewhat less instances of final-stress, suggesting that even an acronym-specific sub-phonology cannot be completely disconnected from the overall grammar. This raises a number of questions; initially we believe that the limits and contents of this sub-phonology must be clearly stated. That is, if morphology does have access to this sub-component of the grammar (as seems to be the case on the basis of our experiment), and can influence the distribution of stress patterns within it, then how much and what type of information can it extract from the grammar, and particularly, is it possible for us to derive information about the grammar from this component? This is not a topic that our investigation set out to answer, but we believe is of crucial importance for the continuation of this discussion.

APPENDIX A

1. Exp.1. Tasks *A* and *B* – Examples of produced acronyms in IPA

Task A

Participants were given the organisations' full title and were asked to provide an IPA transcription with syllabification and stress. For example:

- Νέο Αναλυτικό Τιμολόγιο Έργων Οδοποιίας ("New Analytical Pricings for Street Constructions") would provide answers like 'nat.erg.o, 'na.te.o, na.'te.o etc.
- Ομοσπονδιακή Επιτροπή Τραπεζικών Υπαλλήλων ("Federal Committee of Bank Clerks") would provide answers like o.e.'ti, o.'e.ti, o.me.'ti etc.

Task B

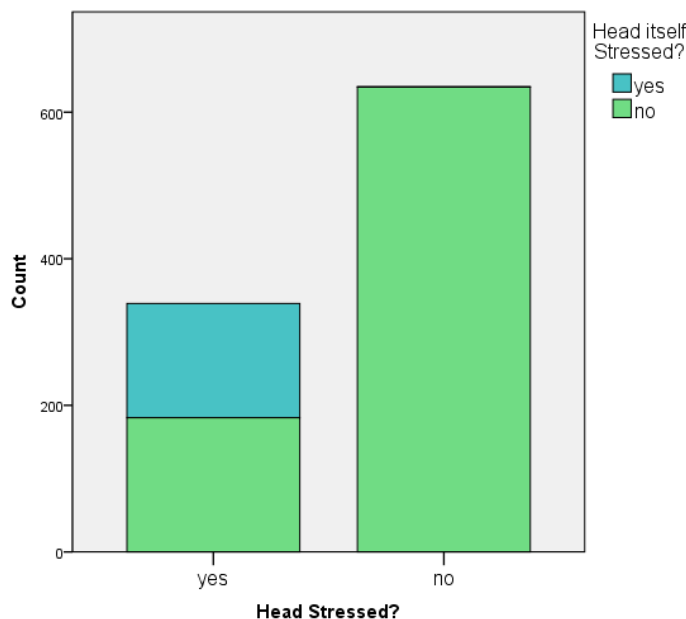

Participants were given the organisations' full title and acronym and were asked to provide syllabification and stress. For example:

- Γενική Εταιρία Κατασκευών ("General Construction Company")→ΓΕΚΑ would provide answers like 'ye.ka or ye.'ka
- Νομαρχιακή Εκτελεστική Επιτροπή ("Prefectural Executive Committee")→NOMEKE would provide answers like no.'me.ce, no.me.'ce.

APPENDIX B

1. Exp.1. Tasks *A* and *B* – Influence of position of morphosyntactic head on stress patterns

In tasks *A* and *B*, 64% of the constructed acronyms did not receive stress on the syllable containing the morphosyntactic head, which means that only 36% of the acronyms were stressed on the head. Out of those instances, in less than half (156 out of 339 tokens) was the actual syntactic head stressed (that is, the head started with a vowel). Comparable results were found in Experiment 2.

2. Exp.1. Tasks *A* and *B* – Influence of vowel hierarchy on stress patterns

Vowel hierarchy did not emerge as a major contributing factor to stress position; out of all the tokens where violation was possible (since not all acronyms have a segmental make-up that allows for violation, e.g. acronyms containing the same vowel in all syllables, or vowels of equal sonority) half of the items respected the hierarchy and half did not (305 violating vs. 308 non-violating tokens). The effect of vowel hierarchy revealed a half-half split, which suggests that, even though its effect might not be statistically significant, it might act as a contributing factor to stress position, a fact to be investigated in the future.

WORD DERIVATION IN CHILD SPEECH: EVIDENCE FROM PRESCHOOLERS

Marina Tzakosta

Maria Hadzidaki
University of Crete, Greece
martzak@edc.uoc.gr

ABSTRACT

The goal of this paper is to assess word derivation, more specifically diminutive and augmentative formation, in the speech of preschool native speakers. Cross-linguistic studies as well as studies on Greek diminutivization have exempted the role of morphology in word formation. Here, using a picture naming task we show that, on the one hand, certain phonological aspects of Greek, such as stress, word position and syllable structure, and, on the other hand, external factors such as frequency rates are involved in word formation processes. Our findings underline the fact that apart from morphological variables, additional language-internal and language-external variables need to be considered in word formation learning and teaching.

1. Introduction

Word formation is a very productive process which is active during language development. Most importantly, it reveals the capacity of the acquirers of a language to master their mother language's vocabulary and, eventually, the morphophonological characteristics of the latter (cf. Werker et al. 2002). In general, in Greek and cross-linguistically, derivation is defined as a word formation process which usually takes the form of affixation (cf. Pállη 2005). Diminutivization applies mostly in the form of suffixation. It primarily expresses affection and is broadly used in child-directed speech (hereafter CDS). Before we turn to the Greek facts and in order to compare cross-linguistic and Greek child data, it is important to present how diminutives are formed in child speech in various languages.

In Russian, diminutivization is a non-regular but frequently attested process. It takes the form of suffixation; the use of suffixes depends on word gender and word phonological shape. Some representative examples are provided in (1) below.

- (1a) sestra 'sister',
(1b) sestr**ICHKa** or sestr**JONKa** 'sister-DIM.'

According to Voeykova (1998), the preference for certain suffixes depends on high input frequency; it is only after the age of 1;08 years that 'conscious' use of diminutive forms starts in child speech. However, such claims do not lead to safe conclusions since they come from one child only (Voeykova 1998).

In Lithuanian, diminutivization is the most frequent word formation process. Like in Russian, it takes the form of suffixation and –again – the preference of certain suffixes depends on high input frequency. Savickiene (1998) claims that diminutive vocabulary enrichment is reported – like in Russian –after the age of 1;08 years. The most frequent suffixes seem to be *-elis* and *-ele*, for the masculine and the feminine gender, respectively. This is shown in (2a) and (2b) below.

- (2a) sen-**elis** 'grandfather',
(2b) sen-**ele** 'grandmother'

In Finnish, which is an agglutinative language, simple diminutivization is realized by suffixation and stem changing processes. Suffixed diminutivization is illustrated in the data in (3a-b) and stem changing diminutivization is exemplified in (3c-e) (Laalo 1998).

- (3a) -nen → kala 'fish' - kalanen 'little fish'
(3b) tyttö 'girl' - tyttönen 'little girl'

- (3c) nenu ‘little nose’ - derived from nenä ‘nose’
- (3d) simmu ‘little eye’ - derived from silmä ‘eye’
- (3e) kännny ‘little hand’ - derived from käsi ‘hand’

However, diminutivization is not a frequent word formation process in adult speech, although it is a frequent process in child and child-directed speech. The data from one child acquiring Finnish as a mother language report the extensive use of the second type of diminutivization, namely stem changing diminutivization, already by the age of 0;10 years (examples in (3c-e)). This preference is explained by the fact that the products of diminutivization are forms which are characterized by their ‘easy’ and simple phonological shape (Laalo 1998), i.e. their simple syllabic and prosodic structure. In Greek, for example, diminutive suffixes are usually composed by simple syllabic structures lacking complex onsets and codas and are characterized by the unmarked prosodic patterns, i.e. they are disyllabic. This is the case with the diminutive suffixes *-aci* or *-ula*.

Hebrew diminutivization is realized through two fundamental processes; suffixation and reduplication which are both productive and frequently attested. Representative examples are provided in (4a) and (4b), respectively.

- (4a) kos ‘glass’, kosit ‘wineglass’
- (4b) kaxol ‘blue’, kxalxal ‘light blue’

Data come from eight children (age range: 1;02-5;06) and from this point of view we can make some general assumptions based on them. More specifically, diminutive forms emerge rather late in child Hebrew, i.e. after the age of two. Hebrew children do not make use of adult forms and prefer to produce diminutives of the *-i* pattern (cf. Ravid 1998).

In Italian, data from one child varying in age between 1;04-3;09 display that diminutivization takes place through suffixation and infixation. Recursivity is quite frequently and early attested in child speech, as shown in (5a) (De Marco 1998). According to De Marco (1998) semantic acquisition in Italian occurs only after augmentatives also emerge.

- (5) albergh-ett-uccio ‘hotel-dim-dim’

The remainder of the paper is organized as follows: in section 2 we discuss the literature on diminutive formation in Greek, while section 3 presents the methodology followed for the design and realization of our experimental task. Section 4 presents and discusses the results while section 5 concludes the paper.

2. Diminutive formation in Greek

The central aim of this paper is to investigate word derivation in the speech of Greek preschool children with typical language development. Therefore, the focus is placed, on the one hand, on the mechanisms which drive the activation of word formation processes in acquisition and, on the other hand, on whether these mechanisms are only morphological in nature or whether word formation is driven by extra-morphological, i.e. phonological principles, such as stress placement, word position, and syllabic structure complexity.

Given the existing literature on Greek, diminutives appear around the age of 2;0 in the speech of native speakers of Greek (Stephany 1995). Diminutivization seems to be determined by transparency of meaning, transparency of morphology, and productivity (Dalalakis 1996). In other words, diminutive forms have specific meaning, and, as a result, specific anaphora, and they are easy to decompose since they are morphologically simple and transparent. This is in accordance with the ideas developed in Dalalakis et al. (1999) who have reported that complex words take longer to process than simpler ones independent of length. Moreover, morphologically transparent complex words are processed faster than lexicalized complex words. For example the word κουκλ-άκ-ι is more transparent than the originally diminutive form σακάκ-ι which is not considered to be a diminutive form anymore; it is rather a lexicalized word. In addition, morphologically licit decomposition is easier than morphologically unmotivated decomposition. This is attested in the cases of κουκλ-άκ-ι vs. αυγ-ουλ-άκ-ι.

In addition, Dalalakis (1996) tested nine subjects diagnosed with Developmental Language Impairment (DLI) who varied in age between 5;0 and 16;0 years of age. Dalalakis tested 80 real (62,6%) and 20 novel words (42,4%) on the basis of two tasks, one testing comprehension and one testing production. The results showed that subjects performed better in the comprehension task

(82,2%) as opposed to the production task (75,6%) in real **-aki** diminutives. Both DLI and typically developing controls showed that performance improves with age.

Thomadaki (2007) reported that the **-aki** suffix is the most frequently attested followed by **-ula** and **-itsa**. She further claimed that type frequency rather than token frequency contributes to suffix productivity.¹ In addition, the emergence of new diminutives is related to child vocabulary growth in general.

3. Methodology

The aim of this paper is to investigate the productivity of word formation processes at the level of both diminutive and augmentative forms. The tested diminutive and augmentative suffixes are provided in (6) and (7), respectively, and are drawn from the suffixes corpus of Πάλλη (2005). The reasons we have opted for these specific suffixes are that, first, following Thomadaki (2007) these diminutive suffixes are the most frequently attested in the data and, second, both the tested diminutive and augmentative suffixes have equivalent phonological structures. More specifically, diminutive and augmentative suffixes are mostly disyllabic (with simple syllabic structures). In this template, the first syllable of diminutive suffixes is stressed.

άκι, -ούδι, -ίτσα,
- ούλης/ -ούλα/ ούλι

(7) - αρος/ -αρα
- ακλας/ -ακλα
- ος/ -α

Our participants have been 20 monolingual Greek-speaking preschoolers with typical language development, 11 girls and nine boys, whose age ranges between 4-6 years. Our tool has been a picture naming task consisting of 20 pictures. Subjects were asked to derive 20 nominal words with literal meaning from already existing nominal forms. The data were collected through free interaction with the children in true class settings. The task directed our subjects to produce diminutive, augmentative and compound forms; however, the former was designed in such a way so as to avoid any bias regarding the use of specific diminutive and/ or augmentative suffixes. The data were recorded and orthographically transcribed.

Our working hypotheses are summed up in the following; first, derived forms are more frequently attested compared to compound forms given the simpler morphophonological structure of the former. Second, diminutives are preferred to augmentative forms due to input frequency effects in CDS, and, third, certain suffixes are more frequent than others due to phonological principles.

4. Results and discussion

The data massively show that derivation, in general, and diminutivization, in particular, are very productive word formation processes. This observation is in line with the existing literature on Greek child speech. More specifically, d preferred to compounding with a 95% production rate as opposed to a 5% rate. We argue that this behavior is expected given that compounding presupposes semantic knowledge of the constituents of the compound form as well (cf. Tzakosta 2009, 2010, 2011a, b, Tzakosta & Manola in press, Kalligiannaki & Tzakosta under review, Tzakosta & Mamadaki this volume). Previous research has demonstrated that compound forms are more complex in the sense that they are polysyllabic words and undergo stress readjustment (cf. Ralli 2007, Tzakosta 2009, 2010, 2011a, b).

In addition, diminutives are preferred to augmentatives in ~65% of the tested cases. Diminutive preference is further inferred by the fact that ~40% of the augmentative forms are not successfully answered as opposed to 15% of diminutives. Graph 1 presents the rates of emergence of diminutive and

¹ However, Thomadaki (2007) does not make clear why type frequency rather than token frequency contributes to suffix productivity.

augmentative forms. More specifically, ~60% of the tested forms are used both in their diminutive and augmentative shape. In addition, 30% of the tested forms are used only in their diminutive shape in as opposed to a less than 5% preference for only augmentative forms (see examples in (1)). Almost 10% of the tested forms, a rate which is quite high, do not appear in their diminutive or augmentative form (see representative data in (1b)).

Graph 1 Use of dim & augm suffixes

- (1a) varel-**ák**-i 'small barrel-NEUT.NOM.SG.'
- (1b) varéli 'barrel- NEUT.NOM.SG.' (S4)
- (1c) vivli-**ák**-i 'small book-NEUT.NOM.SG.'
- (1d) vivli**ár**-a 'big book-FEM.NOM.SG.' (S5)
- (1e) melis-**úl**-a 'small bee-FEM.NOM.SG.'
- (1f) méli**sa** 'bee-FEM.NOM.SG.' (S8)

- (1h) krevát-**a** 'big bed-FEM.NOM.SG.' (S10)

Graph 2 presents the statistical rates of the diminutive suffixes most frequently attested in the data. Our results are in line with Thomadaki (2007). More specifically, -aki is massively produced by preschool native speakers of Greek, followed by all other suffixes which exhibit much lower rates. It is worth mentioning that non-diminutive forms display a 10% rate of emergence.

Graph 2 Frequency rates of diminutive suffixes

In addition, there are sparse cases of diminutive recursivity as shown in (2). Though not frequently, attested, such data verify the dynamics of recursivity in word formation.

(2) mil-**ar-ak-ák**-i ‘small apple-NEUT.NOM.SG.’(S1)

Graph 3, on the other hand, presents the statistical rates of the augmentative suffixes most frequently attested in the data. –αροζ/ -αρά is the most frequently attested augmentative suffix. Like in graph 2, the non-augmentative forms exhibit a very high percentage (~40%), much higher than most augmentative suffixes.

Graph 3 Frequency rates of augmentative suffixes

If we observe the facts depicted in graphs 2 and 3 in combination, we may conclude that the high rates of non-diminutive and non-augmentative forms are due to the fact that, first, word formation is not completed in the speech of preschool children. In addition, augmentative forms are more ‘difficult’ especially because of their low frequency in CDS. For example, we argue that the pnce for the –άκι suffix is attributed to the fact that diminutive production is favored by frequency effects; –άκι displays much more familiarity effects in CDS compared to other diminutive suffixes. Moreover, the target language’s phonology affects production; diminutive suffixes carry word lexical stress as opposed to augmentative suffixes. This is illustrated in (3). Therefore, suffixes which carry lexical stress are firstly acquired and produced. Conversely, suffixes with variable stress patterns are more susceptible to being perceptually ignored.

(3a) péd-aros ‘beautiful boy-MASC.NOM.SG.’

(3b) cefal-áros ‘big headed-MASC.NOM.SG.’

Finally, graph 4 displays the production rates of compound and non-compound forms. It is more than obvious that non-compound forms exhibit much higher rates compared to compound forms. We claim that non-compound forms are preferred because, first, compounding is a ‘difficult’ word formation process which presupposes acquisition/ knowledge of inflection and derivation. It also presupposes a quite large vocabulary size since a compound lies on the semantic knowledge of compound constituents. Second, the development of word formation knowledge is not a sole morphological phenomenon; it depends on a combination of factors which drive language development, such as frequency rates in CDS as well the acquisition of phonological principles which are activated at each stage of language development. Such phonological principles are word position, stress and syllabic structure complexity.

Graph 4 Production rates of compound and non-compound forms

5. Conclusions and relevant implications

The aim of the present study was, first, to investigate word derivation in the speech of Greek preschool children with typical language development. More specifically, the focus was, on the one hand, on the mechanisms which drive the activation of word formation processes in acquisition and, on the other hand, on the examination of whether these mechanisms are morphological in nature or whether word formation is driven by extra morphological strategies.

Our results revealed that the development of word formation is not a morphological phenomenon only but it depends on a combination of factors which influence language development. Such factors are frequency rates in CDS, vocabulary knowledge and the acquisition of phonological aspects of the language being acquired.

Our working hypotheses have all been verified; more specifically, derived forms are more frequently attested compared to compound forms given the simpler morphophonological structure of the former. In other words, derived forms are massively preferred to compound forms since derived words presuppose the activation of simpler word formation mechanisms. Second, diminutives are preferred to augmentative forms due to input frequency effects in CDS, and, third, certain suffixes are more frequently attested than others due to phonological principles.

Such findings underline the fact that all the above factors need to be seriously taken into consideration in class and whenever language teaching material is designed. We firmly believe that if the order of acquisition of word formation mechanisms is taken into account in language planning, then L1 and L2 teaching will be facilitated and more effective.

In this paper we have tested fundamental but not all of the phonological principles which may be related to word formation. More specifically, we examined frequency effects, stress patterns and syllabic complexity but we have not taken word position into consideration. That would be a priori difficult given that diminutive and augmentative formation takes the form of suffixation which means that right word edges are favored. However, it would be useful to test whether the right edge of the word (suffixation) is more effective than the left edge of the word (prefixation). This is an issue left for future research.

martzak@edc.uoc.gr

ABSTRACT

In this paper we evaluate the linguistic mechanisms which determine compound formation in the speech of L2 learners of Greek. More specifically, we used a structured questionnaire in order to test one-word compounds produced by Bulgarian, Romanian and Russian learners of Greek. Our findings were compared to findings from other studies on L2 compound formation. The data revealed that there are specific mechanisms which determine word formation and compound learning. We claim that such mechanisms are driven by Universal Grammar and their use in language teaching would facilitate language learning.

1. Introduction and theoretical background

Compounding is the most complex word formation process because it presupposes, on the one hand, the acquisition of derivation and inflection, and, on the other hand, vocabulary knowledge of the language being acquired or learned. One-word Greek compounds – or, else, lexical compounds are of two major types; [[**stem**] + [**stem**] + **derivational suffix**] and [**stem** + **word**] compounds. Words like *lemon-ó-dasos* ‘lemon forest – NEUT.NOM.SG.’ in which stress is shifted belong to the first type. In *lemon-o-dásos*, on the other hand, the second compound constituent preserves its morphophonological characteristics, i.e. its prosodic shape, gender and inflectional endings; therefore, it belongs to the second compound type (Drachman and Malikouti Drachman 1994, Malikouti-Drachman 1997, Nespor and Ralli 1994, 1996, Ralli 1992, 2002, Pállη 1996, 2005, 2007).¹ Two-word compounds belong to the so-called morphosyntactic – or, else, ‘loose’ – compounds (cf. Κολιοπούλου 2006, Pállη 2005, 2007) which fall outside of the scope of the present study.

Most research has focused on the theoretical analysis of compound forms (Drachman and Malikouti Drachman 1994, Malikouti-Drachman 1997, Nespor and Ralli 1994, 1996, Ralli 1992, 2002, Pállη 1996, 2005, 2007); however there is growing research on the perception and production of Greek compounds by atypical populations (cf. Jarema et al. 1999) and L2 learning of English nominal and deverbal compounds by Greek learners (cf. Agathopoulou 2003). The present study investigates the acquisition of Greek compounds by L2 speakers of the language placing emphasis on Bulgarian, Romanian and Russian learners of Greek. Our research questions are related to the examination of the mechanisms which drive compound formation as well as the extent to which these mechanisms are drawn from a shared pool of repair strategies among languages. More specifically, we are interested in investigating the degree to which Universal Grammar or both influence L2 compound learning irrespective of the learners’ linguistic background.

The first studies with typically developed adults, and typically developing preschool and primary school children have been conducted by Tzakosta (2009) and Τζακώστα & Μανωλά (in press), respectively. In these and related studies which will be discussed below data were collected on the basis of two off-line structured questionnaires. T(est)1 examined the formation of existing real compounds such as *spanakopita* ‘spinach pie-FEM.NOM.SG.’, whereas T(est)2 investigated the formation of non-existing morphologically possible but semantically ambiguous or vague compound words, such as *molivopita* ‘pencil pie-FEM.NOM.SG.’. The scientific goals of this experimental task are, first, to delve into the mechanism which drive compound formation, second, to investigate the degree to which

mnemonic or true word formation mechanisms determine compound formation, third, to examine the extent to which universal word formation strategies govern compound formation in different target groups irrespective of the typological similarities/ differences of mother and second languages or whether these similarities/ differences prescribe word formation.

Tzakosta (2009) makes a first survey on the tendencies that Greek native speakers exhibit regarding compound formation, especially with respect to some of its major aspects. The study revealed that Greek native speakers do not make mistakes in the formation of existing compounds, though they can produce variable forms which are equally grammatical/ acceptable (Test 1). Variability is connected to stress assignment and, consequently, to the preferred compound type, i.e. [[stem + stem] + deriv. suffix] or [stem + word] as well the occurrence (or not) of the linking vowel. However, variability in word formation is not extensive regarding headedness. Heads are almost exclusively located at the right edge of the compound. Head perception is ambiguous only in novel compounds (Test 2). Moreover, test 2 bared an extensive degree of variation in the formation of non-existing forms. The linking vowel appears across-the-board in compounds whose second constituent starts with a consonant. Its emergence is optional if the second constituent starts with a vowel. Linking vowels are always present in [stem + word] compounds. Apparently, they do not emerge due to the impact of phonology, but rather due to the selection of a specific compound structure over another. Mnemonic knowledge governs the formation of existing forms (Test 1). However, non-existing novel compounds are formed mainly on the basis of word formation processes (Test 2).

Τζακώστα & Μανωλά (in press) demonstrated that primary school Greek children improve faster compared to preschool Greek children. They assume that this is due to systematic teaching during the educational process. They further showed that a) accurate perception of compound heads, b) the function of the linking vowel, c) the alternative use of different compound structures, i.e. [[stem + stem] + derivational suffix] and [stem + word], in combination with d) the possibility for stress readjustment and stress shift without change in meaning are important cues for language instruction. According to Τζακώστα & Μανωλά (in press), accurate comprehension of the mechanisms which are relevant in compound formation has two further implications.² First, it facilitates the perception of monomorphemic³ or polymorphemic words and the successful morphological segmentation of the latter. Second, this metalinguistic capacity provides preschool and primary school children with the additional possibility to incorporate newly acquired or learned words in word families and to understand the historical, structural and typological connection of Modern to Ancient Greek.

Additional studies on the acquisition of compounds by L2 learners based on the experimental material presented above (Tzakosta 2009) have been conducted by Tzakosta (2010, 2011a, b) and Kalligiannaki & Tzakosta (in press). More specifically, Tzakosta (2010) revealed that Dutch adult learners of Greek provide equivalent results with Greek native speakers with respect to the performance of the L2 experimental group regarding the variables of headedness, the linking vowel, the compound types and stress shift/ readjustment with the addition that L2 learners are highly influenced by their mother tongue (L1 transfer). As a result, the emergent compound types develop fused characteristics carrying properties from both Dutch L1 and Greek L2. Like native speakers, the L2 experimental group displayed that activation of mnemonic knowledge is extensive in T1 but not attested in T2 which is governed by word formation mechanisms.

In addition, Tzakosta (2011a) who tested Turkish learners of Greek demonstrated that both native speakers and L2 learners of Greek draw from the same pool of learning strategies governing compounding. However, it is important to note that Turkish L2 learners of Greek are also highly influenced by their mother tongue. It is important to note that the recruitment of two different age groups of Turkish learners of Greek revealed that older speakers have better knowledge of Greek. More specifically, all L2 learners show a preference for [[stem + stem] + derivational suffix] forms in both tests. Again like native speakers of Greek, Turkish L2 learners display strong activation of mnemonic knowledge in Test 1 as opposed to Test 2.

Moreover, Tzakosta (2011b) tested German learners of Greek and came to the conclusion that German learners of Greek display equivalent patterns of variation like native speakers of Greek. Tzakosta's assumption is that this is due to the fact that, to some extent, both native speakers and L2 learners draw from the same pool of universal constraints governing compounding. Like in the case of the studies discussed above, compounding in the speech of German L2 learners of Greek seems to be highly influenced by L1 word formation mechanisms. This L1 influence tends to be minimized in the

² Cf. Γαβριηλίδου (2004) for additional proposals.

³ We assume single morphemes words to be words which are inflected but not derived or compound (Tzakosta 2004).

speech of speakers who reach a high level of proficiency in Greek. Mnemonic knowledge is minimized in the formation of non-existing words both in L2 where word formation is productive.

Finally, in the same line with the previous studies, Kalligiannaki & Tzakosta (in press) exemplified that Albanian, Russian and Swedish L2 learners of Greek could potentially be (or become) bilinguals given the major findings of the data; first L2 groups provided equivalent results to L1 preschool acquirers of Greek, though they did not score as high as native speakers. Second, there is clear variation in the scores of different L2 groups; more specifically, the Russian and Swedish speakers performed better than Albanian learners in the formation of both existing (T1) and non-existing (T2) compounds. The discussion regarding the general characteristics of compound formation in Greek, Albanian, Russian and Swedish revealed that Greek is typologically more adjacent to Russian and Swedish than Albanian. In other words, typological similarity is responsible for the fact that the Swedish and Russian speakers perform better in forming compound words than the Albanian speakers. Therefore, the closer two languages are regarding their morphological synthesis the easier and faster they are learned or acquired. This entails that the inter-language typological adjacency should be seriously taken into consideration in the design and substantiation of the relevant teaching material and the teaching methods.

To sum up, all of the above studies' findings move to the same direction. More specifically, L2 learners of Greek exhibit equivalent tendencies to native speakers regarding compound formation and both acquirers and learners of Greek draw from the same pool of repair mechanisms which determine compound formation.

2. Objectives of the study and research methodology

The goals of the present study are summed up in, first, investigating the perception and production of Greek one-word compounds by Bulgarian, Romanian and Russian learners of Greek, and, second, exploring the preferred compound types, the position of heads, the role of the linking vowel, and, the emergence of morphologically variable forms.

We recruited 10 Greek native speakers and 10 L2 learners of Greek (two Bulgarian, two Romanian and six Russian) who were asked to fill in two written questionnaires, T1 and T2; we used the questionnaires designed and used in Tzakosta (2009) and subsequent works which demanded the formation of nominal and deverbal compounds. T1 examines the formation of real compounds (215 forms), like *pefkodasos* 'pine forest-MASC.NOM.SG.', while T2 investigates the formation of novel compounds (155 forms), i.e. morphologically possible but semantically non-existing words, like *molivodasos* 'pencil forest-MASC.NOM. SG.'.

Our theoretical approach is differentiated from the one followed in Kalligiannaki & Tzakosta (in press). More specifically, we do not rely on the typological similarities or differences between Greek and the mother languages of our subjects in order to evaluate the validity of the mechanisms activated during compound formation. Conversely, we deliberately 'ignore' such linguistic aspects and exclusively rely on the data per se in order to make generalized teaching proposals without taking the learners' linguistic background into consideration. In other words, we adopt a more pedagogical rather than linguistic approach of our topic.

Our working hypotheses which are based on the findings of relevant previous studies (cf. Tzakosta 2009, 2010, 2011a, b, Τζακόστα & Μανωλά in press, Kalligiannaki & Tzakosta in press) are the following:

- Both Greek native speakers and L2 learners of Greek are expected to prefer producing [[stem + stem] + derivational suffix] compounds because of the unmarked prosodic pattern of the latter. In other words, [[stem + stem] + derivational suffix] compounds are characterized by stress shift which results in the untepenultimate stress pattern of Greek.
- linking vowels/elements comprise compound perceptual cues. In other words, linking vowels/elements are supposed to drive accurate compound perception and production.
- Heads almost always emerge at the right edge of the word for both native speakers and L2 learners.
- Native speakers' and L2 learners' compound perception is influenced by language frequency and language use. Words of high frequency are not recognized as compounds; therefore, they are produced based on mnemonic knowledge. On the contrary, words of low frequency are produced through the activation of word formation mechanisms.
- Mnemonic mechanisms are activated in T1 while true word formation capacity is attested in the formation of novel compound forms.

- Both native speakers and L2 learners draw from the same pool of word formation mechanisms governed by Universal Grammar (hereafter UG).

3. Results and Discussion

In this section we present the results of our data regarding the major variables tested in this study, namely the preferred compound type, the position of heads and the emergence of the linking vowel. Graph 1 presents the statistical results of L2 learners regarding T1, i.e. the questionnaire which evaluates the formation of existing compounds. The first interesting outcome is that irrespective of the L1 linguistic background of our subjects they all show equivalent tendencies. More specifically, it seems that heads and the linking vowel constitute important perception and production cues since they exhibit very high rates of accurate and correct emergence in the data for both native speakers and L2 learners. Moreover, although native speakers do not make a clear preference for [[stem + stem] + derivational suffix] or [stem + word] compounds, Bulgarian and Russian learners show a preference for [[stem + stem] + derivational suffix] compounds, while Romanian learners opt for [stem + word] compounds. In addition, native speakers and Bulgarian and Russian learners productively use variable forms like *ponokefalos* vs. *kefaloponos* ‘headache-MASC.NOM.SG.’ without any change in meaning. In relation to that, it seems that our subjects have a good knowledge of the Greek vocabulary since the rates of non-answered questions and non-compound forms emerging instead of compound ones are very low for all groups of learners.

Graph 1 Statistical results for existing compounds (T1)

Graph 2 enhances the validity of the results of T1 in the sense that T2 data move to the same direction like those in T1. More specifically, heads correctly appear at the right edge of the word and linking vowels accurately emerge where needed almost across-the-board for all groups of subjects, native speakers and L2 learners. The rate of non-answered questions in T2 is low for native speakers and Bulgarian L2 learners but is very high for Romanian and Russian learners. At the same time, variable forms emerge extensively in the data of native speakers and Bulgarian learners and are almost non-existing in the data of Romanian and Russian L2 learners. This might imply that Romanian and Russian learners are still in the process of learning compound formation mechanisms, which are, in turn, evidence for vocabulary mastery. Moreover, [[stem + stem] + derivational suffix] compounds are clearly preferred by all subjects groups. We assume that this is proof for the fact that unmarked patterns, like the antepenultimate stress template, emerge when true word formation mechanisms are activated.

Graph 2 Statistical results for non-existing novel compounds (T2)

Such results verify all our working hypotheses. To sum them up, it appears that all subjects groups prefer to produce forms which fall within unmarked phonological patterns. All groups use cues for accurate perception and correct production of compound forms. More specifically, heads and linking vowels determine to a great extent correct production of both existing and novel compounds. However, we cannot ignore the fact that word use and word frequency govern mnemonic mechanisms. Novel compounds, on the other hand, are governed by UG repair strategies.

The data further showed that all subjects groups' statistical results are related to the proficiency level of the learners rather than the typological similarities and/ or differences of the learners' L1 background with the L2 target language. This further implies that the same teaching methods can be used for different learners' groups. More specifically, the structure of compound types, headedness and the use of the linking vowels, constitute important perceptual and teaching cues and facilitate morphology and vocabulary learning.

4. Conclusions

In this study we tested the capacity of Greek native speakers and Bulgarian, Romanian and Russian learners of Greek to form compound words. The data revealed that irrespective of the morphological synthesis of the learners' L1 background, both native speakers and L2 learners demonstrate equivalent results for most tested variables. In other words, certain linguistic aspects, such as unmarked stress patterns, the use of the linking vowel and right headedness constitute strong perceptual cues, and, consequently, strong teaching tools for all groups. Moreover, the results of the present study are in line with the results of previous studies (cf. Tzakosta 2009, 2010, 2011a, b, Τζακόστα & Μανωλά in press, Kalligiannaki & Tzakosta in press); this supports our claim that UG mechanisms determine word formation even at advanced proficiency levels.

ABSTRACT

Η παρούσα μελέτη εξετάζει την κατανόηση κλιτικών και αυτοπαθών αντωνυμιών στην Ειδική Γλωσσική Διαταραχή (ΕΓΔ). Παρουσιάζονται τα αποτελέσματα μιας δοκιμασίας επιλογής εικόνας, που χορηγήθηκε σε 14 ελληνόφωνα παιδιά με ΕΓΔ και σε δύο ομάδες ελέγχου 48 παιδιών τυπικής ανάπτυξης (ΤΑ). Τα παιδιά με ΕΓΔ παρουςίασαν έλλειμμα στην κατανόηση των αυτοπαθών αλλά όχι των κλιτικών αντωνυμιών σε συνθήκες συντακτικά απλών προτάσεων, ενώ τα παιδιά ΤΑ είχαν υψηλές επιδόσεις και στα δύο είδη αντωνυμιών. Σημαντικές δυσκολίες διαπιστώθηκαν στα παιδιά με ΕΓΔ αλλά και στα παιδιά ΤΑ στην κατανόηση των κλιτικών και όχι των αυτοπαθών αντωνυμιών σε συνθήκες συντακτικά σύνθετων προτάσεων.

Keywords: clitics, reflexives, *na*-clauses, secondary predicate constructions, specific language impairment, Greek

1. Introduction

Cross-linguistic research on the acquisition of pronominal and anaphoric reference has shown that while typically developing (TD) children do not have problems interpreting reflexive anaphors (*himself*, *herself*) (1), sometimes they erroneously allow strong pronouns (*him*, *her*) to co-refer with an inter-clausal antecedent (2) (Chien and Wexler, 1990; Grodzinsky and Reinhart, 1993). However, further research has revealed that children's interpretation of pronominal elements varies across sentence constructions; co-reference errors do not appear with quantificational antecedents (3) (Chien and Wexler, 1990; Philip and Coopmans, 1996; for a different view see Elbourne, 2005) or in cases where clitics are involved instead of strong pronouns (4) (Baauw, Escobar, and Philip, 1997; Escobar and Gavarró, 1999; McKee, 1992; Varlokosta, 1999/2000). Moreover, asymmetries have been observed in the interpretation of pronominals in simple contexts compared to more complex ones; while clitics are well-interpreted in simple transitive clauses (4), they are misinterpreted in Exceptional Case Marking (henceforth, ECM) contexts (5) (Baauw et al., 1997; Escobar and Gavarró, 1999; Hamann, Kowalski, and Philip, 1997; Varlokosta, 1999/2000). Erroneous interpretations in ECM contexts are evident in the case of strong pronouns as well (6), giving rise to a much stronger effect than the one reported for clitics (Philip and Coopmans, 1996). In contrast, reflexive anaphors tend to be well-interpreted across conditions, simple clauses (1) and ECM constructions (7).

(7) Mum_i sees *herself*_{i/*k} dance

[Child language: Mum_i sees *herself*_{i/*k} dance]

Selective asymmetries in the interpretation of pronominal and anaphoric elements have been also reported for children with Specific Language Impairment (henceforth, SLI), a developmental language disorder, typically associated with normal non-linguistic cognitive abilities but severe difficulties in language comprehension and production (van der Lely, 1996; among others). However, the findings reported in the existing studies regarding the observed asymmetries in the interpretation of pronominals and reflexives are not always compatible. In particular, van der Lely and Stollwerck (1997) report that performance of their English-speaking SLI group on conditions with strong pronouns was worse compared to conditions with reflexives in the case of sentences with referential antecedents; the pattern was reversed in the case of sentences with quantificational antecedents, with reflexives presenting greater difficulties compared to strong pronouns. In contrast, in an online priming study, Hestvik, Schwartz, Tornyoova, Almodovar, Love, and Swinney (2007) observed good comprehension of pronouns by English-speaking SLI children who were impaired in structures derived by *wh*-movement. The authors argue that the deficit observed in SLI children concerns true movement relations and not pronominal/anaphoric relations, which are encoded at a non-syntactic level of representation. In a similar vein, Novogrodsky and Friedmann (2010) present evidence of intact performance regarding the interpretation of strong pronouns and anaphoric reflexives by their group of Hebrew-speaking SLI children, despite observed impairments of the group in the production and comprehension of structures derived by *wh*-movement (relative clauses and *wh*-questions). They also conclude that SLI children do not have difficulties with all kinds of syntactic dependencies (contra van der Lely, 1996; van der Lely and Stollwerck, 1997). Studies on the comprehension of pronominal clitics present controversial findings, as well. Jakubowicz, Nash, Rigaut, and Gérard (1998) do not observe difficulties regarding the interpretation of pronominal clitics in their group of French-speaking SLI children, who produced coreference errors in only 10% of the cases, whereas Varlokosta (2002) reports some difficulties regarding the comprehension of pronominal clitics in her group of Greek-speaking SLI children, who produced coreference errors 28% of the time. Great difficulties are observed by Varlokosta (2002) in the performance of her SLI cohort on strong pronoun conditions, where coreference errors were produced in 50% of the cases. In contrast, Stavrakaki and van der Lely (2010) report that their group of Greek-speaking SLI children present a deficit in the interpretation of pronominal clitics (55% correct performance) but not in the interpretation of strong pronouns (87.5% correct performance) or reflexives (100% correct performance). Last, an asymmetry in SLI children's interpretation of clitics in simple transitive sentences compared to complex contexts has been reported by Varlokosta (2002): whereas clitics are misinterpreted in simple transitive clauses, like (8), in 28% of the cases, they are misinterpreted 67% of the time in complex contexts that involve a secondary predicate construction (SPC), as in (9); interestingly, very few misinterpretations are found in complex contexts that involve a *na*-clause, as in (10), where coreference errors are observed in only 17% of the cases.

(8) O Gufi_i *ton*_{*i/k} skepase
Goofy covered him

(9) O Gufi_i *ton*_{*i/k} iðe ðemeno
Goofy saw him tied up

(10) O Gufi_i *ton*_{*i/k} iðe na xorevi
Goofy saw him dance

It is apparent that the cross-linguistic findings regarding pronominal and anaphoric reference in SLI are inconclusive since it is not clear (a) whether the interpretation of strong pronouns presents greater difficulties compared to the interpretation of reflexives (van der Lely and Stollwerck, 1997 vs. Hestvik et al., 2007; Novogrodsky and Friedmann, 2010), and (b) whether the interpretation of clitics is unproblematic or less problematic compared to the interpretation of strong pronouns (Jakubowicz et al., 1998; Varlokosta, 2002 vs. Stavrakaki and van der Lely, 2010). Moreover, the findings of the two Greek studies concerning pronominal and anaphoric reference in SLI raise the following issues: (a) Is the comprehension of pronominal clitics less deficient compared to the interpretation of strong pronouns? (Varlokosta, 2002 vs. Stavrakaki and van der Lely, 2010); (b) Is the comprehension of pronominal clitics more deficient compared to the interpretation of anaphoric reflexives? (Stavrakaki and van der Lely, 2010); (c) Is the comprehension of clitics better preserved in simple contexts compared to complex contexts? (Varlokosta, 2002).

In the present study we address some of the above issues by investigating the comprehension of pronominal clitics and anaphoric reflexives in a group of 14 Greek-speaking SLI children with a picture selection task. In particular, we examine (a) whether the comprehension of pronominal clitics is more deficient compared to the interpretation of anaphoric reflexives in simple transitive clauses, and (b) whether performance on clitics becomes more deficient in complex structures that involve a *na*-clause or a SPC. Unlike Varlokosta (2002), where the SLI group was indirectly compared to TD children without strict matching procedures, we compare our SLI cohort to two control groups of TD children, one matched on language ability and one matched on chronological age.

2. The present study

2.1 Participants

The participants of the study were: Fourteen (14) monolingual Greek-speaking children with SLI (12 male), aged from 5;5 to 7;10 years (mean age: 6;2, SD: 0.77), and two control groups of TD children: (a) one group matched on language ability (LA) (n=28) on the basis of raw scores from a subset of the Diagnostic Test of Verbal Intelligence (DVIQ) (production of vocabulary) (Stavrakaki and Tsimpli, 2000), aged from 3;11 to 6;0 (mean age: 4;7, SD=0.65) (see Table 1); and (b) one group matched on chronological age (CA) (n=28), aged from 5;0 to 7;8 (mean age: 5;9, SD=0.87). Each SLI child was matched individually for language ability to two TD children (within 3 points of the DVIQ). The SLI and CA groups were matched individually for chronological age (within 6 months); there were no significant differences in chronological age between the two groups ($p > .1$). All children demonstrated a normal range of nonverbal IQ, in addition to hearing and spatial acuity preservation, no history of frank neurological impairment, no psychological or emotional disturbance, and none received any kind of medications.

SLI group	Age (years/month)	DVIQ scores (vocabulary)	LA group	Age (years/month)	DVIQ scores (vocabulary)

Table 1 Participants (SLI and LA): Age and DVIQ scores

2.2 Materials and procedure

A picture selection task was employed, which contained 40 clauses in 8 different conditions divided into simple and complex contexts: (i) simple contexts: referential antecedent with a clitic (11); referential antecedent with a reflexive (12); quantificational antecedent with a clitic (13); and quantificational antecedent with a reflexive (14); (ii) complex contexts: clitic in a *na*-clause (15); reflexive in a *na*-clause (16); clitic in a SPC (17); and reflexive in a SPC (18). Simple structures contained 6 sentences per condition, whereas complex structures included 4 sentences per condition.

Dad saw him dance (<i>na</i> -CL) | [complex context] |
| (16) | <i>O babas ide ton eafto tu na horevi.</i>
Dad saw himself dance (<i>na</i> -RFL) | [complex context] |
| (17) | <i>O babas ton ide demeno.</i>
Dad saw him tied up (SPC-CL) | [complex context] |
| (18) | <i>O babas ide ton eafto tu demeno.</i>
Dad saw himself tied up (SPC-RFL) | [complex context] |

All participants were presented with two black and white cartoon pictures at a time in one page of A4 size, while they heard a test sentence that corresponded to one of these pictures. Participants then were asked to point to the correct picture. Test sentences always followed an introductory sentence to set the context. The pictures depicted two occasions: one which matched the spoken sentence (the *match*) and one which did not match the spoken sentence (the *mismatch*) (see Fig. 1 for an illustration of test sentence 11). All items were randomised across conditions. Fillers were also included and the order of the pictures (presented on the left or right side) was reversed across conditions, in order to avoid habituation effects. A few practice items were included prior testing in order to make sure that children were familiar with the procedure. Repetition of test sentences was allowed, when necessary. The task was administered within one session.

Fig. 1 Introductory sentence: *Ehume enan baba ce enan maθiti.* We have a dad and a student.
Test sentence: *O babas ton zografizi.* Dad is painting him.
Picture A: *match* (correct) / Picture B: *mismatch*

3. Results

Our data revealed that Greek-speaking SLI children have selective difficulties in the comprehension of clitics and reflexives. As it is shown in Table 2, pronominal and anaphoric reference in simple contexts does not cause difficulties to SLI and TD children given the relatively high scores of accuracy all groups attained (above 79%). However, although no asymmetries were observed between clitics and reflexives in simple contexts for both TD groups ($p > .1$), the SLI group performed significantly better on clitics (with a referential or a quantificational antecedent) compared to (a) reflexives with a referential antecedent ($\chi^2=8,513$, $p=.004$; *Cramer's V* = .225); and (b) reflexives with a quantificational antecedent ($\chi^2=10,573$, $p=.001$; *Cramer's V* = .251).

	CL	RFL	QNT-CL	QNT-RFL	na-CL	na-RFL	SPC-CL	SPC-RFL
SLI group	0,94 (0,23)	0,79 (0,41)	0,94 (0,23)	0,76 (0,42)	0,59 (0,49)	0,86 (0,35)	0,52 (0,50)	0,91 (0,28)
LA group	0,95 (0,21)	0,87 (0,33)	0,85 (0,35)	0,87 (0,33)	0,57 (0,49)	0,91 (0,28)	0,61 (0,49)	0,89 (0,31)
CA group	0,97 (0,17)	0,95 (0,21)	0,95 (0,22)	0,95 (0,21)	0,57 (0,49)	0,94 (0,24)	0,57 (0,49)	0,99 (0,09)

Table 2 Overall scores (mean/Sdv)

In contrast, the performance of all groups (SLI, LA, and CA) dropped significantly in the complex conditions (*na*-clause, SPC). Specifically, less accurate scores were obtained within all three groups in (a) *na*-clauses with clitics, compared to simple contexts with clitics (SLI group: $\chi^2=25,900$, $p=.000$; *Cramer's V* = .430; LA group: $\chi^2=60,952$, $p=.000$; *Cramer's V* = .467; CA group: $\chi^2=69,649$, $p=.000$; *Cramer's V* = .499); and (b) SPCs with clitics, compared to simple contexts with clitics (SLI group: $\chi^2=34,035$, $p=.000$; *Cramer's V* = .493; LA group: $\chi^2=52,964$, $p=.000$; *Cramer's V* = .435; CA group: $\chi^2=71,770$, $p=.000$; *Cramer's V* = .506). Selective asymmetries in the interpretation of clitics and reflexives were also observed within complex contexts; (a) clitics but not reflexives were misinterpreted in *na*-clauses (SLI group: $\chi^2=10,036$, $p=.002$; *Cramer's V* = .299; LA group: $\chi^2=33,595$, $p=.000$; *Cramer's V* = .387; CA group: $\chi^2=40,510$, $p=.000$; *Cramer's V* = .425); and (b) clitics but not reflexives were misinterpreted in SPCs (SLI group: $\chi^2=17,785$, $p=.000$; *Cramer's V* = .395; LA group: $\chi^2=24,381$, $p=.000$; *Cramer's V* = .330; CA group: $\chi^2=59,321$, $p=.000$; *Cramer's V* = .515).

Additionally, whilst no asymmetries were observed between the SLI and the LA group, reflexives were significantly better interpreted by the CA group compared to the SLI group in simple contexts with a referential antecedent ($\chi^2=16,811$, $p=.000$; *Cramer's V* = .258) and in simple contexts with a quantificational antecedent ($\chi^2=20,571$, $p=.000$; *Cramer's V* = .286).

4. Discussion

The present study investigated the ability of Greek-speaking SLI children to assign reference to pronominal clitics and reflexive anaphors in simple and complex constructions, and compared their performance to the performance of two control groups of TD children, one matched on language ability (LA) to the SLI cohort and one matched on chronological age (CA). Our results from TD children revealed that both control groups (LA and CA) performed high in all simple contexts, while they manifested difficulties with the comprehension of clitics in complex contexts, like *na*-clauses and SPCs. Our results regarding high performance on clitics and reflexives in simple contexts are in line with previous findings for Greek (Varlokosta, 1999/2000; 2002), as well as with cross-linguistic findings (Baauw et al., 1997; Escobar and Gavarró, 1999; Hamann et al., 1997; McKee, 1992), and indicate that TD children acquire reference assignment in simple contexts at an early age. Our results regarding low performance on complex contexts with clitics compared to simple contexts with clitics, as well as the asymmetry observed between complex contexts with clitics and complex contexts with reflexives are also compatible with previous cross-linguistic findings, where similar dissociations have been observed (Baauw et al., 1997; Escobar and Gavarró, 1999; Hamann et al., 1997; Varlokosta, 1999/2000; 2002).

Our results, however, revealed a pattern that was not manifested in previous research on Greek; unlike Varlokosta (1999/2000; 2002), where an asymmetry was observed between *na*-clauses and SPCs, with higher performance of TD children on *na*-clauses compared to SPCs, our findings revealed

similar difficulties regarding the interpretation of clitics in both complex contexts. One difference between this study and the previous studies lies in the choice of experimental task: while in the present study a version of the picture selection task was used, in Varlokosta (1999/2000; 2002), an act out version of the truth value judgment task was employed. The methodological difference between this study and the previous ones may have contributed to the observed differences in the results. We will not analyze further these differences, but for discussions regarding task effects, see Baauw and Zuckerman (2009), Conroy, Takahashi, Lidz, and Phillips (2009), and Sanoudaki and Varlokosta (2011). What is crucial for our purposes is the fact that the difficulties in the interpretation of clitics in complex structures observed in previous studies were replicated in this study as well, and, notably, that these difficulties appear to be persistent in TD children that are 7-year-old (compare with other studies where similar errors have been observed in younger TD children; 3;5 to 6;3 year-old children in Escobar and Gavarró, 1999; 3;6 to 5;10 year-old children in Varlokosta, 1999/2000; 2002). In six of the twenty eight children in the CA group, that were 6;10 to 7;8 (mean age: 7;3), coreference errors were observed 58% of the time in *na*-clauses with clitics and 62.5% of the time in SPCs with clitics. In contrast, performance of these children on *na*-clauses and SPCs with reflexives was 100% accurate. The errors observed in complex contexts with clitics have been attributed to overgeneralization of A-chains (Reinhart and Reuland, 1993) by children, a result that is due to incomplete lexical acquisition of the grammatical features of personal pronouns (Baauw et al., 1997; Philip and Coopmans, 1996). The idea is that children treat pronominal elements as [-R], instead of [+R], resulting in configurations that violate the Chain Condition (Baauw et al., 1997). This approach faces a number of problems, particularly if one takes into account the feature specification of Greek pronominals and reflexives (Nerantzini, Papadopoulou, and Varlokosta, 2011; Varlokosta, 2011). For the purposes of the present study, we will only point out that if one adopts the analysis of incomplete lexical acquisition of the grammatical features of personal pronouns as an explanation for the coreference errors observed in complex contexts with clitics, one has to maintain the idea that the grammatical features of pronouns are not acquired before the age of 8, an idea that seems quite odd and faces empirical problems as well (see Vasić, 2006).

Let us now turn to the findings for the SLI group. Regarding performance on clitics, similarly to the TD control groups, our SLI cohort performed very high on simple contexts. This finding is in line with previous studies that show spared interpretation of clitics by SLI children in simple constructions (cf. Jakubowicz et al., 1998), or less deficient interpretation of clitics compared to strong pronouns (cf. Varlokosta, 2002), but incompatible with studies that show deficient interpretation of pronominal clitics in SLI (cf. Stavrakaki and van der Lely, 2010). The spared interpretation of clitics in simple contexts indicates that (a) SLI children do not have a deficit related to the grammatical nature of object clitics (i.e. to the grammatical features they carry) (contra Tsimpili and Stavrakaki, 1999), and (b) SLI children do not have a deficit related to feature checking in syntactic dependencies that incur movement or chain formation, such as object clitics (contra Stavrakaki and van der Lely, 2010) (for evidence of unimpaired production of object clitics by SLI children, see Manika, Varlokosta, and Wexler, 2011). In contrast, the findings of this study are compatible with approaches arguing that SLI children do not have difficulties with all kinds of syntactic dependencies (cf. Novogrodsky and Friedmann, 2010).
